GOOD workmanship needs no coat of paint to enhance the execution, for like sculptor's work, wood workmanship is best judged in the nude without drapery or color.

WET your bricks, wash your sand, slake your lime, but perish not your mortar with water, or your work will not be worth its bond.

LET no building workman be too proud to take a hint from the humblest laborer that attends him, for the experienced looker-on betimes sees more than the doer.

ARTIFICIAL, like natural drainage, is governed by gravitation, and the absence of a proper fall in either is as opposed to nature as a swamp is to health.

A HOUSE in danger, a family in peril.

THE builder that deceives the architect wrongs the client as well. and if he connives at bad workmanship he demoralizes the workman and constitutes himself a criminal.

Garden mold may be good for vegetables, but as a component of mortar it spells early ruin.

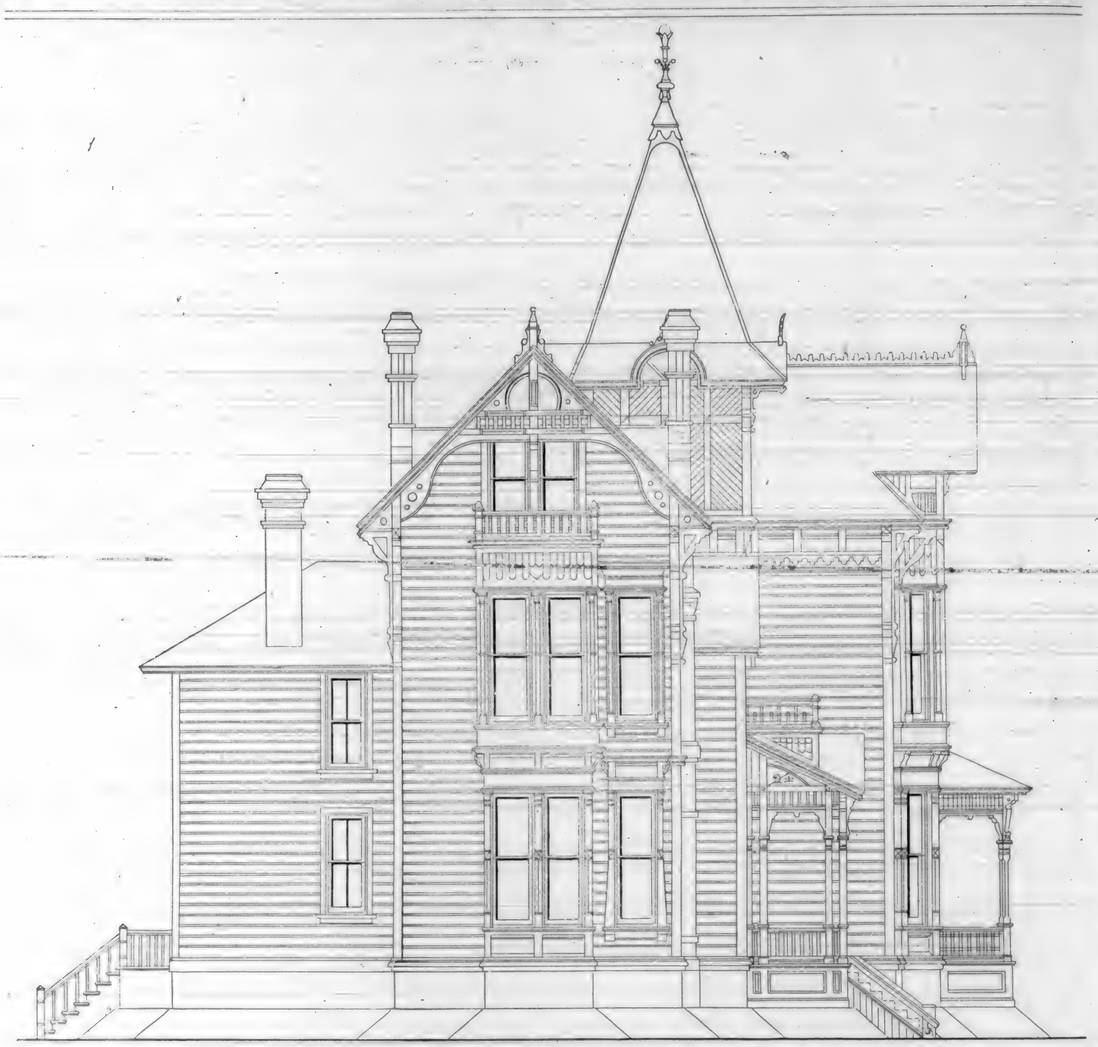

PLATE 3—SIDE VIEW OF COUNTRY DWELLING. COST, ABOUT $7000.

Our Illustrations.

PLATE 1 presents to our readers the elevation of a neat and commodious residence, suitable for a country or suburban dwelling, Plates 3, 5 and 6 being the same house, as seen from different points. Very little ornamentation on the outside has been adopted, the main idea being to show a handsome front with as little expense as possible.

In the arrangement of the rooms, as shown in Plates 2, 4, and 7, some new and striking features will be noticed. The kitchen is a little "snuggery" all to itself, and yet is in distinct connection with the yard, dining-room, and hall; an alarm at the front door can be attended to by the servant without passing through any room. The veranda is so situated that it can be used by the gentlemen for a smoking-room.

The bed-rooms on the second floor are all well supplied with closet-room. The bath-room is in the rear; two windows contained therein, so that perfect ventilation is secured. In the attic are the servant's room, children's play-room, and a billiard-room.

This house can be built for any amount from seven to ten thousand dollars, according to finishes used.

A Plethora of Money.

IN any city the amount of money loaned by savings banks on property is regarded by nearly every one as the thermometer by which the rise and fall in the values of real estate are determined

There is an immense amount of money lying idle in this city. In fact, simply to get it out of the way and that it may earn a little something for its owners, one of our principal savings banks last month invested quite a large sum in U. S. bonds. This one bank now holds nearly $10,000,000 in bonds of our own proud country.

One of the principal causes of this showing is the general prosperity among the working-men. There is no need whatever to run in debt. Consequently on the *pay-as-you-go-and-save-what-you-can* system, thousands of small depositors are placing their money in the banks; and it is these small amounts from a great number of people that is the cause of our savings institutions having a plethora of money.

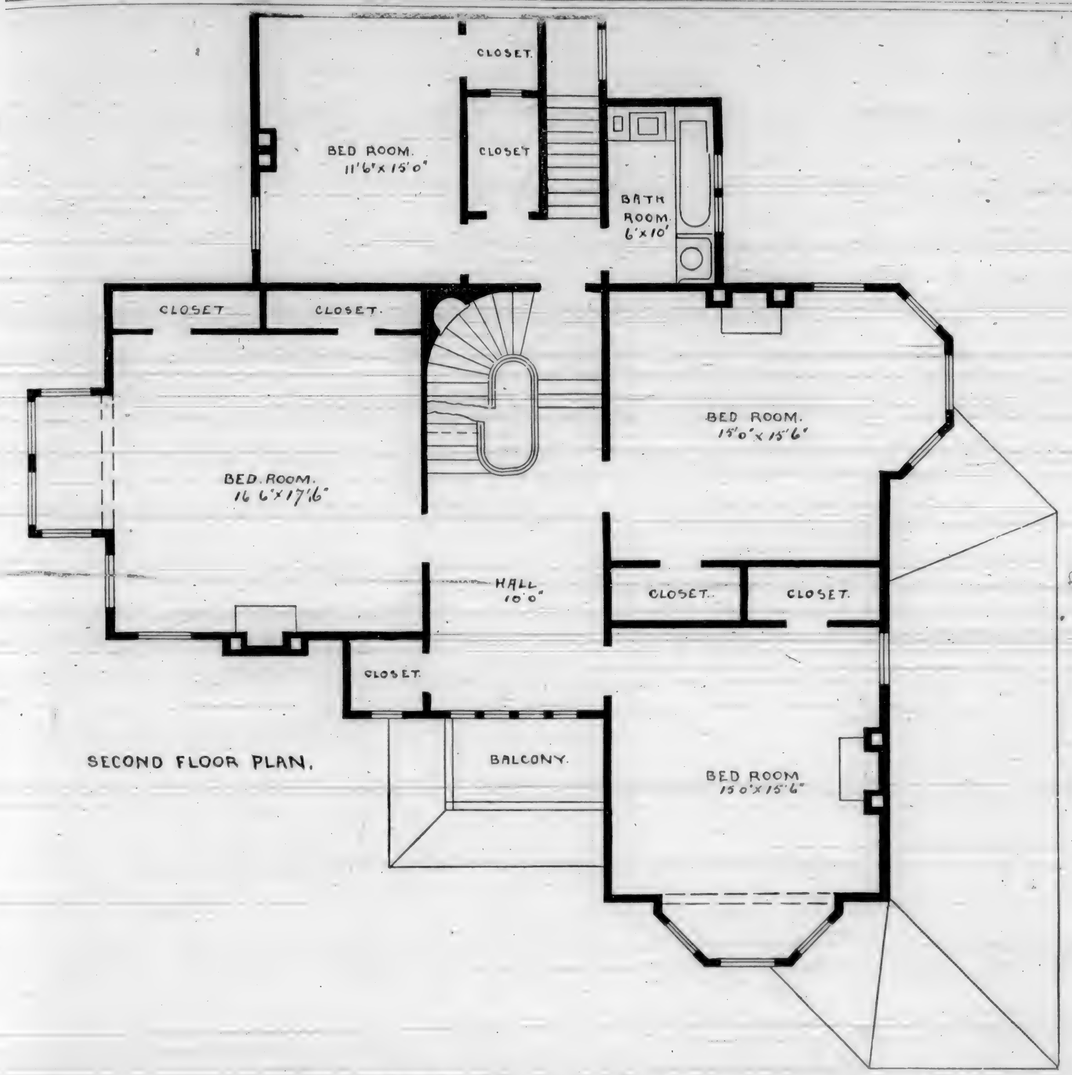

PLATE 4—SECOND FLOOR PLAN OF COUNTRY DWELLING.

Are Plastered Ceilings Obsolete?

MODERN architecture, says a correspondent, in its relation to modern discoveries of new material and the skill of artisans in the use of old material under improved conditions, both in a utilitarian and decorative view, seems to demand something of a departure from ancient methods of constructing and ornamenting buildings.

Weight of material where it does not serve to strengthen or elaborate a design, must certainly be considered obsolete in architecture. In this connection it might be well to consider the impropriety of using plaster ornaments for decorative purposes. In their representation of the vegetable kingdom they are not and can not be true to nature in any proportionate comparison, except it may be its facial outlines. In elaborating architectural beauty or engineering strength, the same may be said with the added detraction that the more we elaborate the more we weaken the structure. Consequently the application of plaster to ornamentation is by some designers but a lingering relic of unskilled artisans, and should, they think, have no place in architectural construction, except as a modeling convenience. They reason that with the skill now being applied in the use of metals and woods of various kinds, even plaster ceilings should be considered as but a temporary and imperfect method of inclosing rooms.—*The Inland Architect and Builder.*

Wheeler's Patent Wood Filler.

WE invite the attention of our patrons to an advertisement appearing in this journal, offering certain paints and "wood fillers," which are recommended as something superior, and warranted to surpass all others in that line. Being as go d as they are recommended to be, they are worth the attention of all architects, painters, wood polishers, and owners.

PERSPECTIVE is necessary in drawings; but do not carry its principles into practice in putting together workmans' ip.

HOUSES may not be built from the roof downwards, though they are often burned in that direction by plumbers' fires.

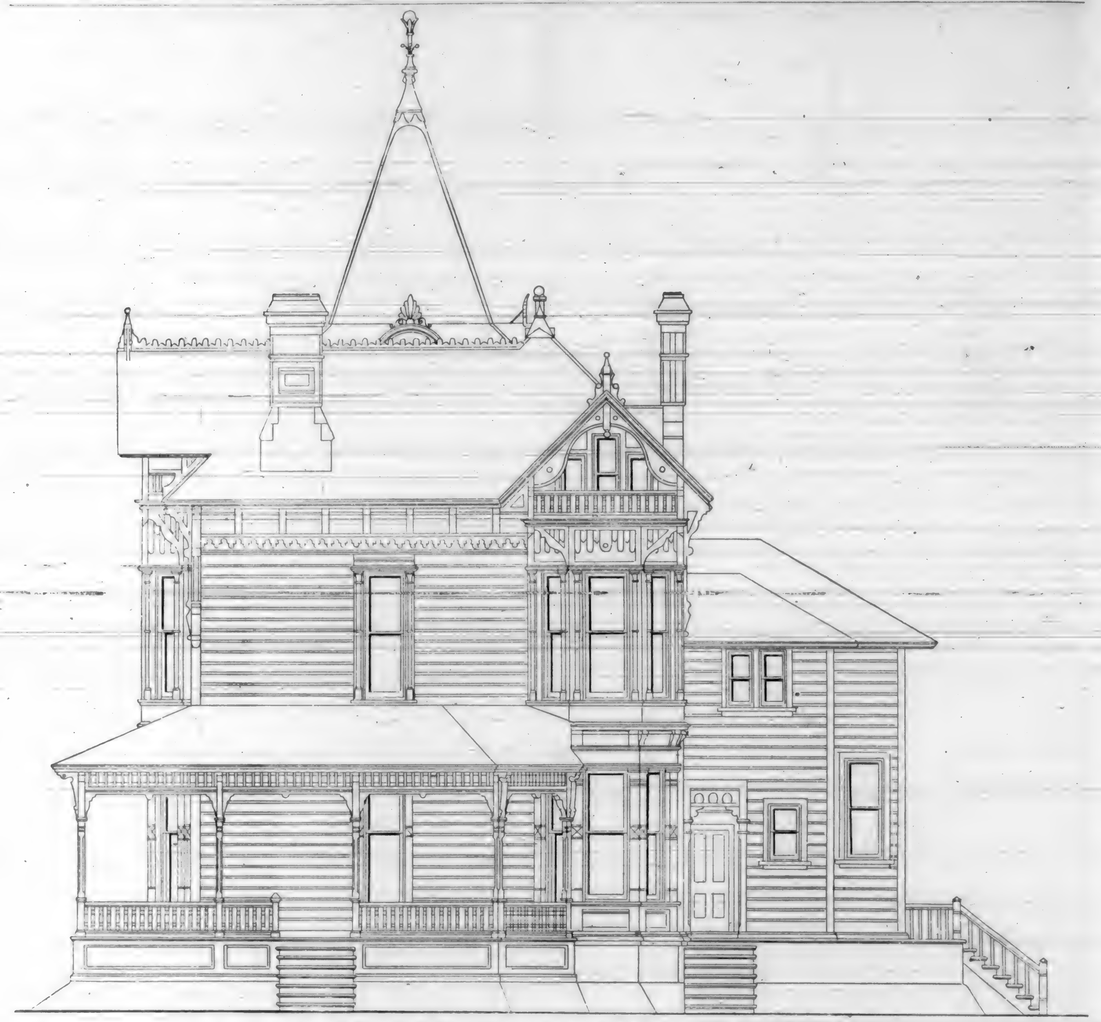

PLATE 5—SIDE VIEW OF COUNTRY DWELLING. COST, ABOUT $7,000.

Look Out For Dampness.

IT would be well for those who move into new houses in the spring to make careful inquiry as to the time when the walls were put up. The increased and unsatisfied demand for houses in this city has induced builders to press their work to completion in spite of cold weather. During the open fall the foundations for many new buildings were laid ; under ordinary circumstances the work would have been postponed until spring. Once begun, the temptation to complete a building has been so strong that walls have been built up in every part of the city when it was so cold that mortar froze, if not as soon as spread, at least during the succeeding night. Such buildings are not fit to live in. The walls will be damp for years, and will be quite sure to cause sickness. A sewer-builder related the following a few days ago : He had been summoned to a house on Prairie Avenue to discover the cause of apparent leakage from some unknown source in the basement. The occupant had an impression that the water came from a sewer. It was soon found that the water, which stood in little pools over the cemented floor, was not sewage. The conclusion was then that it came from the service pipes ; but they were found to be absolutely tight. It was finally discovered that the water had been dripping down the inside of the walls, inside the plastering, and arrested by the cemented floor, had spread out over it and formed the pools spoken of. These invariably evaporated during the night, but the hollows filled again when the sun began to warm the walls in the morning, and the dripping continued during the day. Had there been a wooden floor in the basement, the water would have escaped into the earth and no one would have known it. Inquiry revealed the fact that the house had been built during the previous winter, and an examination of the mortar behind the plastering showed that it was as soft as when laid. It needs no argument that such a house should be avoided. The one in question was a fashionable Southside block.—*Sanitary News, Chicago.*

THE *Lancet* thinks that children should wear woolen next the skin, and wear longer clothing, suspending it from the shoulders and we would hear more of health.

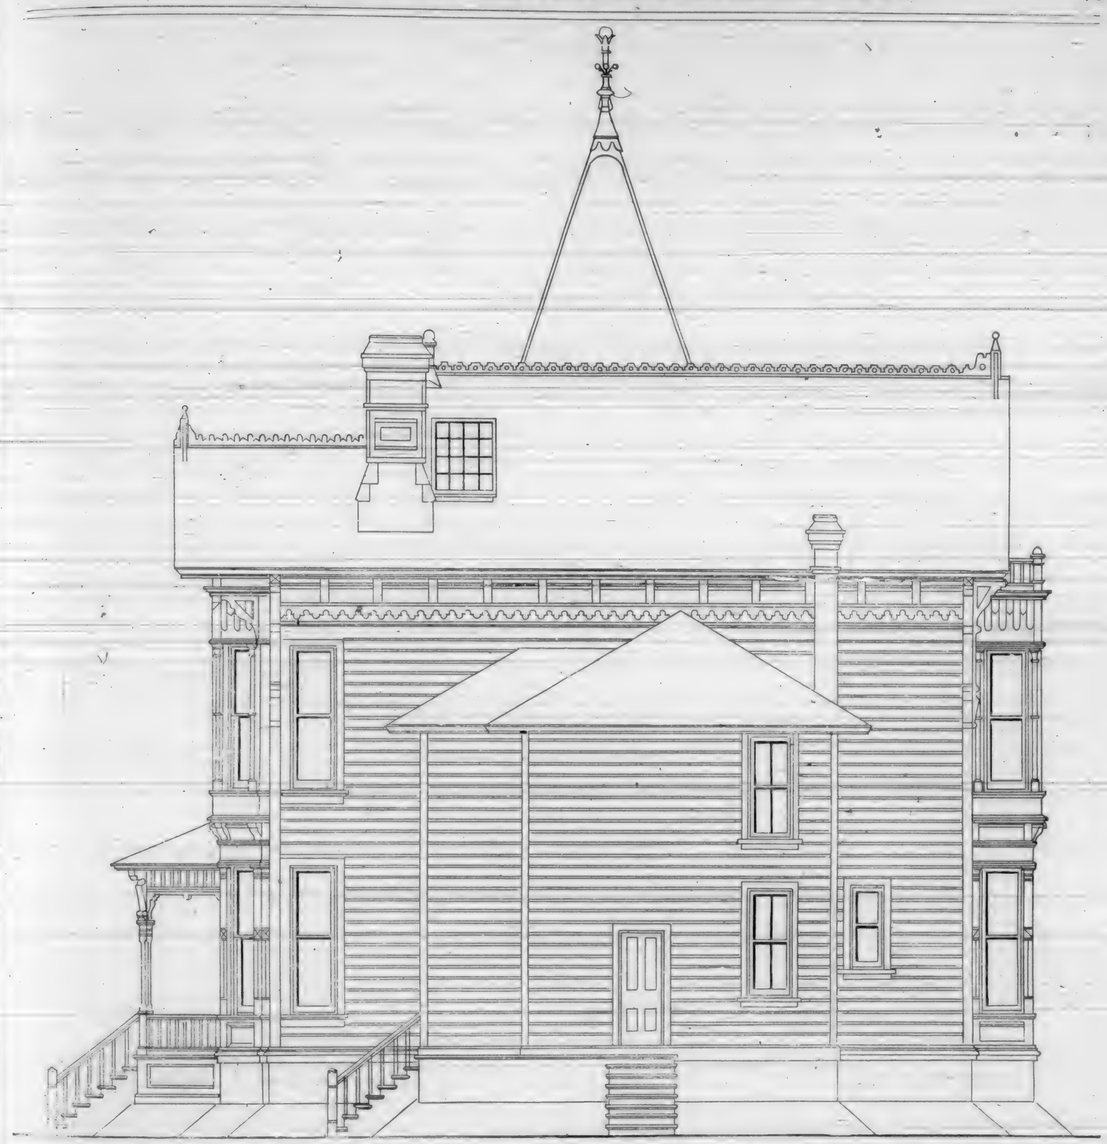

PLATE 6—REAR VIEW OF COUNTRY DWELLING.

Painting Canvas Roofs.

ONE of our readers complains that in painting a canvas roof the quantity of paint necessary to fill the canvas was so enormous, especially in hot weather, that he was quite astounded, using several gallons where he expected to use as many quarts. While this large quantity is an advantage, inasmuch as it is the resisting medium of the roof (and the larger the quantity the better in many respects is the roof), it seems desirable to obtain a coating with a less expenditure of oil and paint. In painting carriages and wagons a very good practice has been to make a quantity of wheat or rye flour paste, and with this give the canvas, after it is laid upon the roof or panel, a good and even coat The paste should be about as thick as that used for paper-hanging. This will leave the canvas as tight as a drumhead, and, at the same time, fill the surface sufficiently to prevent so great absorption of the oil. Glue size has the same effect and is easily applied. It is said that panels painted in this way are very durable, and that the paint never cracks or scales off. White-lead in oil colored with ocher is probably one of the best paints which can be applied upon the roof. Possibly, for the sake of its fire-proof qualities, a final coat or two of mineral paint might be of advantage.—*Metal Worker.*

Revised and Enlarged edition of the Steel Square and its uses now ready—Price $1.00.

A recent decision of the Post Office Department is to the effect that a letter, after being sent, can be recalled by the sender upon his making application to the postmaster, who has authority to recall the same by telegraph.

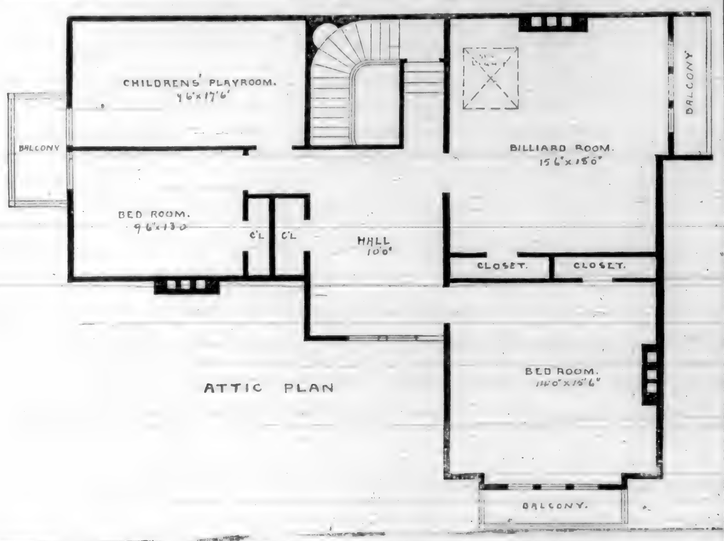

PLATE 7—ATTIC VIEW OF COUNTRY DWELLING.

The "Bulletin's" No. 1 of "New Series."

WE regret that our contemporary has "*deemed it advisable to present another series of similar designs by the same architects*" as notwithstanding the statements of the *Bulletin* to the contrary, the first series possessed no merit whatever entitling it to the respect of any one familiar with the science of architecture. We have yet to find the first architect or qualified builder who has not expressed himself unfavorably in reference to series No. 1. The few meritorious, copied-from-published-books-features that appeared were so unskilfully handled and were so manifestly the conception of others that the *Bulletin's protégé* received *no credit* from informed sources for originality; and the very stupid efforts at specification writing demonstrated the utter unfitness of the plagiarist to prepare an intelligent set of documents. In very many, if not in all of them, there were things written down in the "specifications" which have never been observed in the practical construction of the plans accompanying. We say this upon the broad principle that many of the requirements of the specifications were so thoroughly at variance with all consistent constructive practice, and so entirely unnecessary, that no competent builder ever gave them the least consideration beyond the smile induced by their ridiculousness.

The following, from the editor's remarks accompanying No. 1 of series second, has afforded much merriment to architects generally, seasoned with remarks not mentionable in a respectable journal, to wit: "It is apparent that they (the former series) have been instrumental, in a great measure, in introducing and popularizing a new style of architecture in San Francisco, as is evidenced by the form of many of the dwellings which have been erected here within the past two years." The statement quoted is so supremely ridiculous and erroneous that it would puzzle even the *Bulletin's* man to invent another more thoroughly destitute of truthfulness. Series No. 1 had about as much to do with influencing a change in style of architecture in San Francisco as the explosion of Blossom rock in the Bay of San Francisco some years ago had to do with influencing the various dynamite plots in Russia, England, and other places across the ocean.

It is but little better than a studied insult to the architects in San Francisco to assert that a single one of them, of intelligence and standing, ever derived a single thought from anything that has heretofore appeared in the *Bulletin* or that may hereafter appear from the same source. The introduction of the Eastlake style, as it is wrongfully termed, in the Eastern States was known and understood by architects generally in this city, and examples of the style had been introduced in California before Series No. 1. made its appearance; and whatever inspirations were received leading to the change in style referred to, was from original sources, and not from the imperfect attempts of the copyist who has served the *Bulletin's* purposes of leading innocent owners, in many cases, into trouble, by inducing them to undertake—with mistaken ideas of building values—the erection of buildings at prices beyond possibilities. For, as we stated in our several reviews of the first series, not one of the plans published could, with the then ruling prices for materials and labor, and much less so at the present time, be built as required by the documents defining the materials to be used and the manner of construction, be erected any way near the cost stated. We care nothing for the bolstering up, erroneous statements of the *Bulletin* or its *protégé*, that the figures of cost given have been confirmed by actual experiments. It is not true; and as we have at other times stated, we again repeat, that no one of the entire series could or can be erected for the amount published as the "total cost," making all proper allowance for the changes in price of materials and labor; more especially if all the *unusual* and *unnecessary* things called for were carried out according to the letter of the documents—a something never intended by him, if their author possessed mediocre intelligence as an architect. If not by the rules governing constructive architecture, the rule of commonsense would set aside as unwise and unmechanical many of the written requirements of the former series.

No. 1 of second series is no improvement upon those which have preceded it in the matter of "specification;" and the striking similarity of the *plan* to numbers of others in use removes all idea of originality. The unhandsome and disproportionate perspective elevation alone possessing *features* of originality in the attempts made to change appearances from *scores* of similar designs to be found in published books. As to the total of cost stated, no honest man competent to determine values would risk his reputation in making any such an assertion as that found in connection with No. 1 of series second, as a fair and reasonable estimate of cost. Thirty-three per cent. added will not pay the cost of erecting such a cottage in the manner required by the "specifications," and fifty per cent. more than the "total cost" would leave but little if any balance in the hands of the man who would undertake the work at that advance.

We have expressed ourselves thus plainly, not that we care a fig for our contemporary's departure from its legitimate line of publication, and seeking by unusual methods to increase its circulation, but because of the misleading and deceptive features of the case, in inducing people to anticipate results *entirely beyond possibilities*, and fixing standards of values at rates injurious to honest contractors, as no man living can carry out the requirements of the last nor either of the former issues for the "*total cost*" stated, without considerable loss to himself. And we hold that every attempt, of whatever character, calculated to lessen the opportunities of the working classes to receive fair remuneration for their services, is a wrong deserving the severest rebuke.

Revised and Enlarged edition of the Steel Square and its uses now ready—Price $1.00.

Dr. Ayers on Sewer Gases.

THE doctor recently read a paper before the San Francisco Medical Society, giving utterance to theories upon sewer gases of a dangerous character. We had prepared a lengthy review of the practical fallacies advocated by him, but we are compelled for want of space to lay it aside. There is nothing new in the theories advanced, as they have appeared in published works upon the subject, although the doctor's effort may have impressed those who do not pursue sanitary literature with the idea of originality.

If the doctor is correct in his assertion, that sewer gases are not promotive of "any special type of disease," then indeed is the whole fabric of sanitary science defective and false. For tens of thousands of the ablest physicians and scientific-sanitary engineers and learned men of all classes throughout Christendom have borne testimony to the fact that those gases are both dangerous and deadly in their effects upon human health; and if so, as ninety-seven per cent. of intelligent people believe, they are and should be rated as of "special type," aside with small-pox or any of the numerous malarial diseases which prostrate humanity on beds of illness, and in the order of their operations fill coffins daily. And it will require infinitely better and stronger proofs than the mere say so's of a San Francisco physician, or the author of a book, to disabuse the public mind in reference to a something which has, by the teachings of those fully competent with the doctor to judge of the nature and effects of sewer gases, and the practical experiences and observations of innumerably many intelligent people, become a settled and accepted fact.

The doctor's assault of the plumbing law passed by the late legislature of California, and his ridicule of the appointment of an "engineer" of plumbing work, simply betrays his ignorance of the subject ridiculed. The "engineer" is an imaginary personage of the doctor's invention, as the law provides for no such official. And as the learned gentleman appears not to have investigated the law sufficient to understand one of its simplest provisions, it would have been wiser on his part to have withheld assertions based upon personal, unintelligent notions. It is not only likely, but very certain, that many of those who have assisted in procuring the passage of the plumbing laws referred to are in every practical sense the peers of the learned doctor, in all matters pertaining to sewer gases, and from their practical experience in connection therewith would be able to give the doctor some good advice and information.

A Great Work.

HISTORY OF THE PACIFIC STATES.

It seems to be the fashion in this country, upon the commencement of any great enterprise, to call upon the government for aid that it might be successfully carried to completion. But in the "History of the Pacific States" by Hubert Bancroft, we have an example of what can be done by the genius of one man, unaided by any governmental aid.

For the past fifteen years Mr. Bancroft has kept constantly employed no less than a dozen secretaries, cataloguing, indexing, abstracting and arranging the material from which he writes; and it is the great secret of Mr. Bancroft's success, that he has the faculty of utilizing labor in literary as in business pursuits—leaving to the author only the work of the artist; that of the artisan being performed by the secretaries.

We propose to notice each volume as it appears. We recommend it to our friends. We urge for it the serious consideration of good men; of all who have a family to rear, sons and daughters to educate; and we do so for the following reasons:

Firstly—Such work should be encouraged. The author, Mr. Hubert H. Bancroft, has performed this labor at an immense cost of time and money. Literary work of this kind does not pay pecuniarily. It is impossible that it should. Therefore, if the intelligent and prosperous members of the community withhold from it their sympathy and support, what encouragement is there for any one ever to sacrifice pleasure and gain to the public good?

Secondly—It is a history of our own country. Now, historical knowledge is the most valuable of all knowledge, for the reason that history is the recorded experiences of mankind. By knowing what others have done, we may profit by their successes while avoiding their mistakes. And of all histories, the history of our own country should be read and studied first, because it more nearly concerns us. Children should be educated not only to respect their parents and love their home, but to respect their country and tenderly to cherish its institutions. And how can they know about their country if books are not placed within their reach?

Thirdly—It will pay pecuniarily. The well-informed, intelligent man can make more money than the careless and unthinking. It is not necessary to talk of the benefits to society and to individuals of such a work as this; they are obvious. Therefore, we appeal, with all the strength and influence at our command, to every respectable member of this community, and say buy the works of Hubert H. Bancroft. Subscribe for them all at once, cheerfully, promptly; then read them, and speak of them to your friends, and thereby lend your support to a great and praiseworthy undertaking.

We will speak more fully hereafter of the scope of this great work. The full set will contain thirty-nine volumes. Two volumes are now ready for delivery, and it is proposed to have each successive issue finished so as to be delivered every fourth month.

IN the hand-saws used in England the cutting stroke is a push outwards from the shoulder of the workman. This mode of using the tool has been perpetuated by the Anglo-Saxon race in the United States, Canada, and the British Colonies. The blade of the saw is thus thrown in *compression*, and in order that it may have sufficient stiffness to prevent it buckling, it requires to be made far thicker than if it had to transmit the same force in tension only. The liability to buckle is illustrated by lads beginning to learn to saw, who not unfrequently injure a saw-blade by the unsteadiness of the thrust they give to it, which leads to the teeth catching on one side of the cut and a sharp bend or even a crack being caused in the blade. As it is almost impossible to remedy such an injury perfectly, the saw becomes permanently damaged. On this account chiefly, also, English saw-blades for hand-work are (and require to be) made of a much better quality of steel than would otherwise be necessary.

In Germany, Italy, and most of the European Continent, as well as throughout the chief peoples of Asia, handsaws are used in tension, the cutting stroke being a pull towards the chest of the worker. In consequence, the blades are made very much thinner than those of English saws, less material is converted into saw-dust and less exertion is required for given rate of cutting.

The English method, however, has this advantage, that a man standing upright can exert a considerably greater force in thrusting forward with his arms than he can in pulling inward. This is still more the case if he leans forward over his *work* because he can then throw a large portion of his *weight* on the saw-handle to drive it forward. The result is that if an English carpenter be pitched against an equally strong German carpenter, each armed with his own tool, the Englishman will saw through as great, or possibly a greater, length of the same thickness as the German will. But the Orientals *sit* to this sort of work, and planting the feet against the log being sawn, pull outwards by the contraction of all the muscles of the body. As is well known to us from our familiarity with the English style of rowing, this is by far the most powerful attitude into which the human muscular system can be thrown. Thus, unless the peculiar shape and position of his work compels, say, the Japanese carpenter, to assume an awkwardly cramped position, he is enabled, with his thin, broad, saw-blade, to get through his work with far less fatigue and with greater rapidity than an Englishman can.

Thin saws worked in tension, being extremely pliable, are more likely to make a cut that is not quite straight. The thick saw-blade of English or American make has superior stiffness, and, therefore, superior guiding power to keep the advance of the cut always in the same straight line, but this superiority in guiding power is again neutralized by the fact already mentioned of the thrust tending to bend the blade, while the pull on the thin saw tends to straighten its blade.—*Cutting Tools.*

IF the Western Union Telegraph Co., as is stated, has purchased the right to use Baxter's long distance telephone, it will not be long before conversation can be carried on between San Francisco and New York with probably two breaks only.

Revised and Enlarged edition of the Steel Square and its uses now ready—Price $1.00.

Architects Sometimes Wrongfully Blamed.

As a rule, in competitions on plans, where the bidding is not restricted to selected parties, there is generally some one of the number who is wild in his estimate, frequently falling fifteen, twenty-five, and even fifty per cent. below all others. The difference of from ten to twenty-five per cent. is of common occurence; and when the bids are opened, and the low figure announced, those who have figured intelligently very naturally feel a disgust for the low man, knowing that in the sum mentioned there is not a sufficient amount to enable him to carry out and complete the work proposed by the plans and specifications, in a workman-like manner, and pay the actual cost of materials and labor. That the more careful and correct bidders should feel aggrieved, is right and proper, as every undervaluation of work encourages owners in the belief that by a little manipulation, and unrestricted bidding, some simpleton may be found who will obligate to give a dollar and ten or twenty cents worth for every dollar received under the contract. And it being the common tendency of the human mind among all classes of people, to seek the cheapest, without regard to actualities—propositions which present a saving are generally accepted, leaving the contingencies to take care of themselves. Consequently those who name a fair and honest price for the thing proposed, are presumed to be unreasonably high in their figuring, and are rejected; while the mistaken or perchance designing low man is accepted, not upon the quantum merit of the case, but because of the offer to do for a certain sum that which others of better intelligence and more just and business-like purposes feel cannot be done for the amount proposed. If the responsibilities and involvements in such cases, fell exclusively upon those guilty of such business indiscretions, there would be no cause of complaint; for if men will deceive themselves by assuming competency in estimating, while practically ignorant of all correct rules of reaching values, a little of the sweetening of bitter experience is well deserved, and should operate as a corrective. But the fact that the bad influence of all such examples works an injury to others, makes the matter one of general interest, and brings it within the province of reasonable and justified complaint. The wrongful blame upon architects lies in the fact that many of the disappointed give vent to their feelings in disaproval of architects permitting "such fellows to figure in their offices." There may be grounds for such murmuring in some cases, but not as a rule; for every well-informed architect knows full well, and in some cases by bitter experiences, that very low figuring is premonitory of trouble; and architects of intelligence and standing are never anxious to surround themselves with making contract conditions which indicate storms and disagreeable occurrences in the future. Yet, being the managing men in preparing the papers and receiving the bids, they are generally held responsible for the blunders and mistakes of all who are permitted to figure, although unable to know or control the figuring of any. In fact, those who are allowed to figure are generally guarded and careful not to extend any information to the architect, through fear of being "given away," and the webs of obscurity and secrecy are tightly woven around the figuring of those in the competition, so that no one may gain or use the advantages of knowing the figures of others. Consequently the architect should not be held responsible for the irregularities of bidders, inasmuch as he holds and exercises no control over the figuring, and it is a great injustice on the part of competitors to invent and express accusations reflecting upon the office in which they figure, because some one of their own class may have made enormous calculations of costs and values.

We intend no reference to those "architects" who impose upon the public by assumptions, presumptions, and artifices which never enter the minds of intelligent and educated men in the profession, who would scorn to be guilty of an unjust or unprofessional act. Nor are architects always responsible for the admission of all the parties joining in competitions, as owners very frequently of their own knowledge, or through friends, know some "good man," whose estimate is wanted, and who cannot be ruled out by the architect, except at the risk of being charged with special purposes in view, or with motives of a personal character. And further, the "low man" frequently proves to be one who has enjoyed the benefits of large experience, and whose "low figures" are wholly the result of oversight. As in one case within our own experience as architects, the contractor overlooked the entire item of labor, amounting to more than twelve hundred dollars, yet he failed to discover his error until long after the work was commenced. The building was satisfactorily completed, and the loss sustained without murmuring, but the effect was bad, inasmuch as through the error of a competent contractor a building was produced far below its value, and stands to be pointed at as a house costing only a certain sum—which is a fact as far as the owner is concerned, but not so as a whole, as the contractor sunk the amount stated, which does not appear in connection with the contract cost. Numerous illustrations might be cited, showing the absence of a fair, perfect system of figuring among the greater number of contractors operating in San Francisco and we think that complaints should be made in that direction rather than against competent architects, who understand fully that contracts let to good men at remunerative prices, are always attended with more pleasant and satisfactory results to all parties.

SPIRIT of turpentine is now made, says a contemporary, from sawdust and refuse of the saw mill. It is extracted by a sweating process, yields fourteen gallons of spirits, three to four gallons of resin, and a quantity of tar per cord.

Building Activities.

The transactions in real estate during the past thirty days indicate a healthful state of affairs generally, with a large amount of capital still seeking investment in desirable business property. The general talk favors the presumption that, before the fall months roll around, there will be a large increase in the erection of brick buildings for business purposes. At present there are but few of this class under way or in course of plan preparation. As will be seen by our monthly report, building operations are confined mainly to residence and tenement improvements, with no abatement in the number of contracts signed during the present as compared with previous months of the present, and for the same period of the past year. Contractors generally are busy, and all good workmen employed, notwithstanding the inauguration by the Carpenters and Joiners' Union, of nine hours as a day's labor.

A limited number of owners express a disposition to resist the nine-hour system, which went into effect on the first inst., but the opposition is feeble and will in a short time quiet down to an acceptance of the situation, provided the working classes continue the course thus far pursued, of making as little stir as possible in reference to the matter. It is only when movements of the kind are made unnecessarily conspicuous that material opposition is aroused and stimulated. But few owners of real estate will permit their property to remain unimproved, with the prospects of remunerative returns upon investments made in the erection of buildings, whether men work nine or ten hours per day. And past experiences prove that there is less ground for opposition to the new rule than many conjure up. For it is a well-established fact that contracts are let from time to time at nearly the same rates, even with an advance in price of materials and labor in prospect or in force. Ten per cent reduction in the hours of labor by no means increases total cost ten per cent., as the cost of labor on buildings is only about one eighth of the total value, and the increase cannot therefore apply to more than that proportion of the total sum; so that on buildings costing $4,000 under the ten-hour regime, the extra cost figured out by the one-tenth reduction in the hours of labor would increase the total cost, under the nine-hour rule, less than $100.

It is reasonable to presume that there will be a short lull in building improvements at this season of the year, when the greater number of those who can afford the time and expense are preparing for their usual summer vacation to, and sojourn at, the various springs and other places of resort—relaxation and pleasure. At the same time, architects generally have numerous orders in hand and plans in course of preparation, and brisk times are confidently relied upon during the remaining portion of the year.

Revised and Enlarged edition of the Steel Square and its uses now ready—Price $1.00.

Value of Buildings—Results to Contractors.

THE prevailing sentiment in regard to the *Expense of building* is in many respects erroneous. Owners more generally, at the commencement of operations settle upon a sum to be expended, seldom equal to, and more frequently largely below the actual value of the thing contemplated. It is but seldom that an amount is stated, sufficient for the purposes contemplated. More is generally asked for than can possibly be obtained for the sum named, without loss to some one—if the attempt is made to comply with the demand made. Two prominent facts in this connection are worthy of notice, first that THOUSANDS of failures, ending in pro ratio settlements, have occurred in San Francisco, not so much by the wastage and squandering of contract moneys as from absolute shortage in the contract amount, less than actual values. The bread-and-butter price at which the work is undertaken will not permit the slightest departure from rigid economy in every particular, nor permit less than slavish attention to the work in hand. The profit margins are as a rule inadequate to the slightest indulgence other than close application in time and personal labor, and attention on the part of the contractor; and it is only by the exercise of every saving possibility that a majority of buildings are completed, with money enough to pay the bills for material and labor.

The second fact that may be mentioned, is that of the financial condition of eight-tenths of those who undertake contracts for buildings. Aside from a few judicious, thoughtful, careful men, the contractors operating in San Francisco have comparatively nothing to show for their many years of application to building pursuits. Nor can it be charged that our master-builders are extravagant livers, for generally speaking there are but few of them who own a roof over their heads clear of encumberances, while the greater number live in rented houses; all of which goes to sustain the statement, that the contracting business in San Francisco has hitherto been less profitable than it should have been, in view of the very large amount of money handled in building operations. All this is further sustained by the fact that but few indeed of our contractors are entrusted with contracts without bonds; a fact that would not exist, if the financial condition of contractors was such as to inspire confidence on the part of owners and materialmen. Nor is this so because they are generally considered dishonest men, for the integrity of many master-builders is not disputed; but honesty alone will not settle unpaid bills nor satisfy creditors; it requires coin to liquidate financial obligations and square accounts. Honesty in its purest sense may permeate every thought, and every intent and purpose may be pure, but if the ducats are lacking, bills cannot be paid.

It is therefore safe to say that owners, as a rule, have been largely financial gainers in the improvement of their real estate in this city, as those who have done the work cannot make an average showing of reasonably fair financial results and profits.

We do not write this as a rebuke to owners, for if men professing competency to estimate building values, see fit to throw away their time and energies in erecting buildings for less than they are worth, owners would be less than wise not to avail themselves of the benefits thus offered.

The Plumber Movements.

SINCE the April issue of this journal we have received a copy of the code of by-laws adopted by the Master Plumber Association of the City of San Francisco, defining the organic laws and executive rules of the organization. If not as perfect as they might be, they sufficiently exhibit an honest purpose on the part of the members of the society to correct the abuses which have hitherto existed in the plumbing trade, and give clear denial to all the speculations dealt in by those who have raised or repeated the cry of a "political job" in the passage of the plumbing law by the late Legislature of California. Upon the theory that all men are corrupt, the law in question may, like thousands of others framed and passed for good purposes, be used by designing and mischievous men to work out selfish purposes. There are but few laws passed which do not in cases fail to accomplish the object for which they were made. But the law recently passed, through the earnest exertions of the principal plumbers in San Francisco, is not one likely to be allowed to fall into bad hands. Those who secured its passage have a common, general interest in its perfect efficiency; and we cannot believe that the leading men in so important a branch of mechanism as the plumbing business is universally acknowledged to be, will permit the matter to pass from their control as a body into the hands of political tricksters and schemers. The good men of the plumbing art have long felt and groaned under the profligate irregularities which have to a large extent brought more or less disgrace upon the entire craft. So many bad things have been done in the name of "practical plumbers," that a very large proportion of property owners and tenants have accepted the belief that honest and competent plumbers are as scarce as incorruptible legislators in a California state legislature. It has therefore become imperative for their own interest individually, and for the redemption of the trade, that the better class of plumbers should secure such aid and assistance in legal form—all mechanical and sanitary considerations failing—to correct the existing abuses. And now that the regulating and corrective means are under the control of the more intelligent and really practical men in the plumbing business, they will deserve all the ha d things that can be said about them if in the future more perfect plumbing work is not done in this city, and a change in general sentiment in reference to plumbers brought about.

Cheap Piazzas.

PIAZZAS and porches are like parasols, they may be intended for comfort, for ornament, or for both. Probably they ought always to be both ornamental and useful, on general principles everything ought to be so, but the object of these suggestions is to indicate how the comfort of these pleasant adjuncts may be secured without the large outlay which is supposed to accompany the "good, broad piazzas and plenty of them," that form so essential a part of the air-castles of most house-builders. In its simplest form a piazza is an open shed resting against the outer wall of the house. If in the right place and of reasonably good proportion, the plain upright parts, with whatever braces are needed for strength, and the lean-to roof will not be unsightly in appearance—quite the contrary, indeed—and will afford precisely the same comfort as the more elaborate structures with turned bed-post columns, Queen Anne spindles, fantastic scroll-sawed brackets, grooves, beads, and decorations without number, and more striped paints than can be found on a dozen barber-poles. Multitudes of village and country houses are bare and comfortless both in appearance and in fact, that would be transformed into hospitable mansions by simple piazzas, which any man of common Yankee ingenuity could build for himself if he could not afford to pay for the labor. A floor of sound, narrow boards laid an eighth of an inch apart on rough joists resting upon bowlders or brick piers, will last for many years, and a boy can make it. Plain, square pieces of timber, or small tree-trunks cut in the grove and stripped of their bark would serve for posts, and a roof made of sound, seasoned, matched boards, not more than four or five inches wide, the edges painted as they are laid, and both surfaces above and below well painted afterwards, will not even begin to leak till long after it has paid for itself a dozen times over in good solid comfort. Even if after a dozen years a few drops should come through in a driving rain, or from melting snow, it is not a serious matter. We don't keep our soluble groceries nor our best silk dresses on an open piazza, not as a rule, and the tightest roof in the world will not prevent the rain and snow from blowing in beneath it. Such a plain, simple piazza built where it can be pleasantly used and large enough to serve as a semi-out-door apartment is vastly preferable to the high, narrow, formal affairs that are evidently added to the main structure, not because the builder desired to increase the comfort and convenience of the occupants, but because he hoped to increase the external beauty of the building. To build a piazza when it is not needed and cannot be used, is like parading an open parasol in the shade, or hoisting an umbrella when there is no sign of a shower.—*The Builder.*

FROM a study of the maximum temperatures naturally occurring, Mr. L. Liebermann says that a mineral oil, the flashing point of which exceeds 60 deg., may be safely used in all parts of Europe.

Practical Suggestions.

ALL sorts of devices have been made and many patented to prevent the rain from beating in under the bottom edge of an outside door in a driving storm. Many have undoubtedly noticed a great heavy, unsightly piece of inch-and-a-half plank with one edge beveled off, and nailed on the bottom edge of a door to prevent the water from being blown by the force of the wind under the door and into the room. In severe storms these old-fashioned weather strips have not accomplished what they were made for.

A much better and more workmanlike way is to take the door from its hinges, then with a carpenter's plow, holding a ⅜-inch iron, make a groove about ⅜ of an inch deep in the lower edge of the door—that is, across the lower ends of the door-stiles and the lower edge of the bottom rail, taking care to have the inward edge of the groove project when the door is in place—from ⅛ to 3.16 inches beyond the rabbet of the doorsill. After you have made the groove, with a rabbet plane work off the outward edge of the groove until you bring it nearly to a point on the outward edge of the door. This finished, the door can be put in place.

This manner of fixing a door prevents any unsightly strips of wood on the bottom of your door, yet it works well in the case of severe storms.

Some may ask what is the reason. It can easily be explained. The rain beating against the face of the door runs down to the bottom edge, and when the wind is strong, and the space between the door and sill is considerable, the water is blown across the lower edge of the weather strip and door until it reaches the inside edge, where it drips down on to the floor.

With a door made as described the wind may be strong enough to blow the water up the incline on the bottom edge of the door, but if it abates, even only for a short time, the water will run back and drop off the front edge or be blown back again up the incline.

If the force of the wind is so great as to drive the water into and across the groove it will run down the inward edge of the groove and drip off into the rabbet of the door-sill.

Thus it will be seen that it is quite important that the inward edge of the groove should project beyond the edge of the rabbet in the door-sill.

Possibly in extra hard storms, where the door is in a very exposed position, a little water may be driven under a door made this way, but it will be small, and not sufficient to cause any annoyance.

I have often wondered why carpenters and builders always put down door-sills in rooms where all the floors are to be carpeted. In my own house I have taken up all the door-sills between my rooms, and have run my carpets from one room into the other. This is especially desirable when carpets are all one pattern and rooms are used in connection. Carpenters could leave the door short enough to swing over an ordinary carpet, while the removal of the door-sills will aid many a housekeeper in sweeping.

When sills are used, odd bits of oilcloth must be got to cover the sill, and even then along either edge it leaves a good-sized crevice for the accumulation of dirt.—*Rivet, Mechanical News.*

Driven Wells.

GOOD drinking water is just as essential to health as pure air; but it is not always easy to determine if water is pure through the sense of taste or sight; water that contains considerable organic matter is sometimes offensive to the sense of smell; but this is not always the case. The best method of testing for organic impurities is to drop into a tumbler of the water just enough "permanganate of potash," or of "Condy's fluid," to give the water a pinkish color. Any organic matter contained in the water is precipitated after standing an hour, the water losing its color or becoming brownish. If, however, there are no impurities to be acted upon, the water remains of a pinkish color for hours. This is a very simple test, and a valuable one, and were it more frequently employed, and its indications heeded, there would be few cases of fever. The best plan to get pure drinking-water is by means of what is generally known as the "driven well" but which by our plan is nothing of the sort. We have seen an open well, the water of which was dangerous to health, within ten feet of a "driven well," in the water of which no impurities could be detected. It is almost impossible to find an open well of perfectly pure water, and it is hardly possible to find a driven well where the water contains impurities.

The easiest way to make a "driven well," is to get a piece of iron or steel pipe, six feet long and one and a quarter inches in diameter; make a cutting edge at one end by beveling off inside the end of pipe, with a half round file, drive this pipe down a foot or two and then draw it up, and the earth from the hole will be found inside the pipe, and can be pushed out with an iron rod. Repeat this opertion until you have gone six feet; then couple an inch pipe, six feet long, to your cutting pipe; continue this till water is reached, then attach a short piece of pipe having small holes in it, and a plug in the lower end, to your inch pipe, and drop it into the little well you have *dug*; screw on a pump and you have a well complete at about the price Mr. Green charges for the right to drive a pipe into the ground. In the decision of the Court in regard to the Green patent, the judge said, that where the earth was raised up and taken out of the well, it did not infringe Green's patent, which holds good only where a pipe is driven down so as to push the earth aside. But everybody knew that.

It has always seemed remarkable that any one should have bothered with Green's patent, when the plan above described is in all respects preferable and is hampered by no patent. Though small it is just as much an open well as if it were six feet in diameter, and any one has the undoubted right to construct such wells. If stones are encountered they may be broken and penetrated by attaching a piece of round steel, one inch in diameter and two feet long, to the end of the inch pipe. The lower end should be drawn down to a blunt point. We constructed a well on the above plan, using an inch galvanized pipe, and the supply of water is abundant for twenty families.—*Hall's Journal of Health.*

Draughtsmen and Our Draughtsmen's Registry.

DURING the past two years or more numerous applications have been made at the office of this journal by practicing architects in San Francisco, and others from Portland, Seattle, Los Angeles, and various other portions of this State and Coast, for competent draughtsmen; the very reasonable conclusion prevailing that as the representative and official organ of the profession, its management should possess special information in reference to those desiring employment as draughtsmen, and those needing help. These conclusions were and are correct; and with the view of perfecting a system which would place us in communication with the entire draughtsmen's forces in this city and elsewhere, we prepared a registry in which to enter the names of all draughtsmen, charging the sum of $2 50 to each party registering, which amount was intended to operate as a perpetual fee for all time, without increase or renewal. Under this arrangement we have been able to secure engagements to many who might otherwise have remained idle, and suffered a loss in time and wages many times greater than the cost of registration, and some who have availed themselves of the advantages offered have formed advantageous co-partnerships and are doing well. But our motives have been by some misjudged, misrepresented, and theorized and magnified into an attempt on our part to perpetrate a wrong, accompanied with the illiberal idea that our interest in the matter was stimulated by the petty and insignificant sum charged, rather than the *truthful, honest* purpose to assist and place in ready communication both employers and employés. There is so little of reason or veracity, and so much of absurdity in the insinuation, that we should not refer to it were it not that the majority of human minds are ever ready to receive and accept as true any and every statement listened to which affords the opportunity for enlargement and furnishes the basis for gossip and slander. As beasts of prey become more savage by the taste of blood, so do most of human kind give more heed to false representations intended to hurt and defame others. There is a relish and flavor in untruths which satisfy and please the unrefined moral taste of multitudes, who prefer to feed upon the false and untruthful rather than seek the sweet sustainments of honest fact, and who are ever ready to magnify mole-hills into lofty mountains and attempt to reduce the silvery orb of night into a map of moldering "green cheese," by exaggerated representations.

The fact that more or less time is consumed in all cases, and sometimes inconveniently so, in respectful courtesies to those calling for information in this connection; that letters are received and answered, postages and sometimes telegraphic expenses involved, are not considered by those who would have us serve their interests at our own cost and expense. We are willing at all times to expend both time and money in matters of a general character by which our patrons may be informed, instructed, and benefited; but those of the side personal interest assume a different aspect, and it seems to us strange that any intelligent young man should permit himself to reach or accept conclusions so foreign to actual facts as those involved in the subject-matter of this article.

As further proof of our disinterestedness as far as the fee is concerned, we state the fact that we have found situations for a number of draughtsmen who have been short of funds without exacting the fee, but have not entered their names upon the registry. And we shall continue to aid any and all who may call on us, giving preference to those who comply with registry requirements when the supply is in excess of the demand.

Cisterns.

A WRITER in the *Lumber World* presents some facts with reference to cisterns that may prove of interest to the readers of this Journal.

Cisterns of various sorts and sizes may be very cheaply and speedily made. The largest sizes should be made oblong, not more than twelve feet across, to turn brick arch over conveniently, and as long as needed. Round cisterns are best when not more than twelve feet in diameter, and as deep as necessary, though the draft of water is rather hard when more than twenty feet deep, when pumped by hand. To build a cistern, if circular, the earth should be excavated in the shape of an egg, longest down, and rounding at the bottom, making the surface of the excavations as smooth and neat as possible. Three feet from the top dig out a shelf the width of a brick, laying the brick for the arch in cement or hydraulic lime-mortar of as good quality as can be procured. Lay a course of bricks in the mortar all round the shelf, pointing the spaces well between the bricks and behind them. When this is completed, all the spaces being filled up, begin another course about one and one-half inches out from the other, filling-in all pointing as before, so that the cement, when set hard, will bind and hold the course of bricks firmly. This will draw in the cistern three inches. Continue in this way until the hole is about the size of a flour-barrel, filling-in the soil around the arch and above it, and building a neck about two feet high to finish off. The earth around ought to be fully a foot higher than the level, to turn off drainage and keep out surface-water. When this is done the interior of the cistern may be plastered on the earth, when it is firm and solid, placing a large stone or platform of bricks immediately under where the water will fall, in the bottom, and to support the pumptube, if one is used. When an earth-wall is not used, bricks should be laid in courses from the bottom, in cement, with much care, and backing each course well behind with dry sand, that the pressure of the water may not cause leaking, which is very often the case if not properly done.

Cement-mortar is usually made of two parts dry mortar-sand and one part of hydraulic cement. The bottom and walls of the cistern must be well plastered and completely covered with this mortar, without any breaks in it anywhere, at least one-half inch thick. It is best not to get it on too thick, or it may slide down to the bottom. This will dry enough in twenty-four hours to be well covered with a wash of hydraulic cement as thin as it can be laid on with a whitewash-brush. The whole should be carefully gone over with this wash, that all porosities or cracks in the plaster may be thoroughly filled and covered up. Two or three coats of this wash are better than one, as they will render the cistern as tight as a bottle. The more coats of the wash that are put on the less water will soak away through the pores of the plaster, and the tighter it will be. This is a point of considerable importance, and should always be carefully attended to.

It is, of course, convenient, when you decide how large a cistern is wanted, to know how large it ought to be made to hold the required quantity of water. For every foot of depth of the following diameters the cistern will hold:—

For 6 ft.	diameter	7.	barrels of 30 gallons.
" 7 "	"	9.598	" "
" 8 "	"	12.533	" "
" 9 "	"	14.42	" "
" 10 "	"	19.58	" "

A cistern 10 feet deep and 6 feet in diameter holds 2,100 gallons, or 70 barrels of 30 gallons each. The rule for finding the contents of any cistern is to multiply half the diameter in feet by itself. Then multiply the product by 3.1416, which gives the area of the excavation near enough for practical purposes. Multiply this by the depth in feet, which gives the cubic contents in feet. Multiply the last product by 1,728 to get the number of cubic inches. Divide the whole result by 231, the number of cubic inches in a wine gallon, and the product will be the number of gallons in the cistern. This, divided by 30, gives the number of barrels of 30 gallons each.

In conducting water from a roof to a cistern, arrangements ought to always be made for turning it off when full, as the weight of the water is apt to burst the walls if it is allowed to overflow. This should always be carefully looked after, and the conductors ought always to be turned off until the rain has fallen for some time and washed the roofs clean and clear of leaves and other trash. A small wire screen ought also to be placed over the spout-holes in the roof. Professional cistern-builders are apt to slight their work, using too little cement, or too little mortar, or not backing the walls well, or not washing them enough afterward to be tight. Any intelligent workman can make a good cistern after being shown how, and these often do the best work. It is always best to mix small quantities of mortar at a time, using it as rapidly as possible. A round cistern is much more economical of space, and holds more in proportion to depth of wall than a square one. But it is often thought best, in constructing very large reservoirs, to build them square. The following tables of both show the difference in wall and in area:—

SQUARE CISTERNS.

8 feet square	have	64	feet area and	32	feet of wall.
10 "	"	100	" "	40	" "
12 "	"	144	" "	48	" "

ROUND CISTERNS.

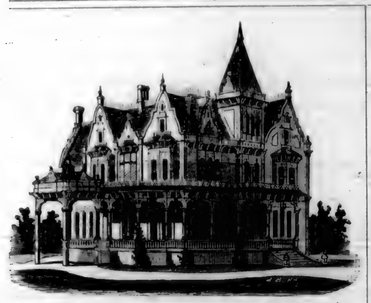
8 feet diameter	have	50	feet area and	24	feet of wall.
10 "	"	78	" "	31	" "
12 "	"	113	" "	37	" "

A 10-foot round cistern, it will be seen, has less wall than an 8-foot square one, and has 14 square feet more surface. Consequently, round cisterns are cheaper and larger than square ones, as well as stronger. In estimating the cost of a cistern the following details are useful. A brick is 8 inches long, 4 inches wide, and 2¼ thick. A wall need not be more than a brick thick, if carefully laid in cement and well backed with dry sand, so the pressure of water, when brought against it, cannot force it out of its place to cause a crack or a leak. When laid flat and lengthwise, seven bricks will make a square foot of wall. A 10-foot round cistern, 12 feet deep, will have 372 square feet of wall, and will require 2,600 bricks for a 4-inch flat wall, if the entire surface is laid upon bricks. But if only an arch is turned of bricks, and the cement-mortar is plastered on sound, solid, clay earth, not more than 1,000 bricks will be needed. Sometimes a wall is laid up with bricks placed on edge, when about 1,700 will cover the entire area, walls, bottom, arch, and all, but this is not a safe method unless a skillful workman attends to the job.

Mix the cement and sand dry before making mortar, as thoroughly as possible, placing the sand on planks, using it about an inch thick, then an inch of cement, and another inch of sand. Then mix and work thoroughly while dry. It is better to pass the whole through a screen, even if the sand has been already sifted. In wetting down, it is best not to mix more than a bucket-full at a time. In plastering the walls always begin at the bottom, allowing each course to set and get hard before putting on another, or the whole may slide down in a lumpy mass.

EDS. ARCHITECT.: "Please settle a difference of opinion by stating the proportion between the load a given floor will bear when the joists are not bridged, and the same floor thoroughly bridged, with two rows of herring-bone bridging."

A floor will not bear any more weight by being bridged. The advantage to be gained by bridging lies in the fact that an individual joist is strengthened thereby, thus increasing its power to resist a concentrated load upon it, such as a heavy book case, safe, etc.



Improvements at Portland, Oregon.

W. S. Strahan is erecting a one-story, double house on D Street between Twentieth and Twenty-first.

W. B. Todd is building a house on Eleventh Street, between H and I, for A. Nolfke. The cost is about $2,000.

James Hyland is having erected four cottages on Eleventh Street, between Stark and B, for Hugh Gearin of Oregon City. They will cost about $4,000.

E. M. Burton has made plans for three double residences, to be constructed on Seventh street near the Trinity church. They are for J. M. Kenworthy, of East Portland, and will cost $12,000.

James Cumming has about finished a new store building on Eighteenth and B streets, for A. T. Smith. It is two-story, 20 x 50, and cost $2,000.

M. S. Rosenblatt is having built a dwelling-house on the corner of Eighth and Alder streets. Sedge & Jenkins are the contractors. The cost will be about $5,000.

There are the frames of three houses on the half block bounded by H. Twelfth and Thirteenth streets. One will be for Mr. Owen, and one of the smaller ones is for Mr. Sheath.

The foundations for J. A. Strowbridge's new block, on Second and Yamhill streets, are well under way. It will be three story, and will cost as much as $50,000,

R. Weeks is building a dwelling, corner Lownsdale and Alder streets. A. C. Townsend is the contractor and Neer & La Romer, architects. The cost is about $2,500.

S. Blumauer is having a house built on Morrison and Fifteenth streets. It is a three-story residence, and will cost over $10,000.

The work of moving the two buildings on the lot owned by John Wilson at the northeast corner of Fourth and Alder streets, has been completed. Mr. Wilson has already contracted with R. Porter for the erection on the lot of a three-story brick building, with basement, which is to contain one single and two double stores. The cost of the structure will be about $40,000.

Mr Roach is building a $5,000 dwelling-house on the corner of Tenth and Market streets.

Mrs. Mary Dooling is building a cottage on the corner of Market and Fourteenth streets, to cost $1,200,

W. W. Spaulding's new three-story brick building on First, between Clay and Columbia, will cost about $20,000.

A two-story dwelling for Frank Hacheney is being built on Hall between Third and Fourth streets, to cost $2,500.

Charles. Cardinell is building a residence to cost between $4,000 and $5,000.

A large two-story double house is being constructed on Third Street between Harrison and Hall, to cost $6,000. M. J. Geist is the owner.

Frank Hacheney is filling two lots on the corner of Clay and Lownsdale streets and will build three two-story frame dwellings, to cost about $4,000.

The northeast corner of First and Main streets has been cleared, and workmen are busily engaged preparing the foundation for a three-story brick, edifice for Watson and Smith. The building will cost about $30,000.

The Catholic school, building in the Dalles will be built of brick, and cost about $30,000.

Plans have been made for a dwelling-house to be built by J. H. Lyon, on the corner of Pacific and Morrison streets, to cost $6,000.

The contracts for the foundations and iron-work of the new building to be erected on the northeast corner of Third and Washington streets by Frank Dekum, have been let respectively to McCarthy & McMahon and John Honeyman & Co.

The work of cleaning out the debris from J. C. Ainsworth's burned building, has been finished and the rebuilding is well under way. Mr. Krumbein, the architect, has let the contract to F. W. Lewis, to be completed June 1st. The improvement will cost $30,000.

The main contract for Labbe Bros.' building has been let to John Robertson. This contract includes all but the foundations and the cast iron work. It is reported that the building will exceed the announced cost—$100,000.

S. Farrell is having built a small cottage on East Park street, between Stark and Washington to cost $1500.

F. B. Winters is building a one-story house on the southwest corner of Pacific and Taylor streets to cost $1,500.

Mrs. E. F. Albright, on Taylor, between Tenth and Eleventh streets, has a two-story dwelling under way, to cost $5,000.

George Cohn is building a dwelling house on the corner of Morrison and Fourteenth streets. It is a two-story, double house, and will cost $6,000.

Mr. Cochrane is building a two-story frame building on First Street, between Clay and Market, to cost about $2,000.

The bids advertised for by the Board of School Directors for finishing up the lower stories of the Failing and Couch schools, were opened at the office of Justus Krumbein, Saturday, and bids for finishing each building were as follows: W. B. Todd, $4,000; W. L. Goodwin, $5,388; Merchant & Bridges, $6,100; Campbell & McDonald, $6,270; Sharno & Davison, $6272; P. O. Lundin, $6,280; N. O. Anderson, $6,325. In case it is concluded to finish only the south half of the Couch building, it will be done for half the prices named.

We are indebted for the above list to the Commercial *Herald*. Our material men would do well to subscribe for the *Herald* as it contains a full account of building operations in the great North west. Terms $3,00 per year.

Absorption of Moisture by Building Materials.

EVERY one connected with buildings of brick and stone knows the absorbent nature of those materials under the most favorable circumstances. It would astonish most people, adds the London *Building News* to be told what a large quantity of water is stored in the brick walls of an ordinary house after a heavy rainfall, the drying or evaporation of which must take place inside in cold weather, unless proper precautions are taken to render the walls impenetrable. The plea for hollow walls has been raised again and again, and though the system is coming to be adopted more generally less, the idea of solidity of wall structure seems to have taken too deep a hold on the ordinary building mind to be given up. Some time ago a suggestion was made that colliery owners and others who have large quantities of slag, might with profit utilize this material for building cottages and other purposes. We are not sure whether the hint was taken, but in some parts of the country the material furnishes an admirable aggregate for concrete. Where good aggregates exist, like slag, broken brick, sand-stone or furnace ashes, concrete building ought to be much cheaper than brick, as no skilled labor is required.

There is another consideration besides cost which tells in favor of concrete, and that is the non-porosity of walls so constructed. Not only does brick absorb moisture in wet weather, but it is now known to absorb animal gases as well; and here we have a condition which builders of our hospitals and infirmaries ought to be reminded of. We are not sure if concrete has been applied to any buildings in England of this kind on a large scale, but as absorbent walls are known to be injurious in harboring the germs of infection, the value of walls constructed of concrete made of burnt aggregates cannot be overrated. Slag made concrete has the great advantage of being fire-resisting, the material in its rough state having been subjected to intense heat. There is nothing in it to "kill" the cement, and the rough surface of walls built with it becomes an excellent "key" for the plastering. In the construction of walls of this material, three sizes of the slag may be used, the larger lumps being packed in layers in the middle of the wall, and the other two sizes, the larger the size of walnuts, run in with cement on each face in the proportion of eight to one.—*Manufacturer and Builder.*

THE trustees of the great suspension bridge over the East River, between New York and Brooklyn, have announced that the structure will be thrown open to the public on the 24th day of May, 1883.

The Effect of the Nine-Hour Movement.

SINCE writing another article appearing in this issue, touching upon the same subject, we have been interviewed by a considerable number of owners in regard to the nine-hour rule adopted by the carpenters' and joiners' union, and we find that a very considerable number of them are disposed not to build at present. We have repeated the arguments elsewhere appearing, that the ten per cent. reduction in the hours of labor increases the cost of buildings ten per cent. only in the cost of that one item; or in buildings where the carpenter's work is worth under the ten-hour rule—$1,000, which indicates in frame buildings a total cost of $7,000 to $8,000, the increase would be only about $100—being one-tenth added to the item of labor. But the further objection is urged, that if the nine hours is recognized by owners, it will soon be followed by a demand for eight hours as a day's labor. We hope not, as such a course will beyond question check present and promised prosperities, not so much because of the actual additional cost of building, as that public sentiment is adverse to such reduction on general principles. Consequently, it will be wise on the part of the laboring classes to be content with what they have gained in the present reduction, and not seek to prostrate building activities by attempting now, what has heretofore been tried and proved a failure. If nine hours had been accepted as a compromise at the time the eight-hour contest was waged years ago, there would have been a yielding on the part of owners, and the ground so gained might have proved permanent, instead of being a partial success, lasting but a short time.

Prescott's Patent Hangers.

THESE new hangers are fast superseding the old styles. No track is necessary where they are used, thus doing away with one of the common petty annoyances experienced by all housekeepers; when parlors are thrown open for a social dance, there is no track to come in contact with one's feet. Another great advantage lies in the fact that the action of these hangers is such upon opening a door, that the latter rises a little, and thus all wear and tear on carpets is entirely done away with. They are very easily applied, and are not visible with the door open or shut. Another great advantage is that they are not affected by shrinkage of either the door or studs. In case they get out of order, they are very easily got at to be fixed. They are made of all sizes and the price is no greater than the old-fashioned sheaves. Many of our architects are adopting them, and they can be found in the residences of many of our wealthy citizens. For full information apply to the agents, Dunham, Carrigan & Co., 110 Front Street.

SHORE up carefully if you would pull down safely.

Women as Architects.

WHY should not American women become architects? They push into all the polite and impolite professions, and architecture with its branch of "house decoration" seems an easy and fitting employment for one who has taste and a head for business. A lady who has recently died in London was a shining example of what can be accomplished by her sex in this department of art. Miss Rhoda Garrett, says the London *Times*, was the daughter of a country clergyman of small means, and one of a large family. She broke through the restrictions of home life, which are much stronger in England than here, and determined to carve an honest independence for herself. She entered the office of an architect, and having learned the trade, so to speak, set up for herself as a "house decorator," taking another lady into partnership. She soon rose to eminence in spite of delicate health, and found time to be the author of a little volume on "House Decoration" which has passed through six editions. Her social and professional life is a strong argument in support of the belief that women—ladies—may quietly succeed in "business," and attain not only money for their own needs, but fame of a high order.—*The Builder.*

About Chimneys.

THE following suggestions from the *American Artizan* for the cure of a troublesome fault of chimneys, raises the point whether it is not better to omit the inside plastering of smoke flues, relying for safety upon good bricks, good mortar, well filled joints, and, if need be, thorough plastering of the outside of the shaft, after it has been carefully inspected. We have several inquiries from subscribers as to the remedy for the formation of creosote in chimneys, which often runs down the walls of rooms, staining carpets and walls and causing much damage. The cause of this state of things, we venture to say, is owing to defective draft, and this often arises from the mason not smoothing the plaster on the inside of the chimney, which causes it to protrude and arrest the progress of the smoke, causing the consequent condensation into a liquid deposit. This may be remedied by attaching a brick to a rope and smoothing off the inside of the chimney. The trouble may arise also from a crooked chimney, in which case the remedy is plain, but the cause we have first assigned will be found to be a common one, and it would be well for those troubled with liquid oozing from chimneys, to look to the state of the inside mortar.

No matter how well arranged, water-closets immediately within a dwelling are objectionable. The minimizing of the evil partly lies in keeping them as far as possible from the sleeping-rooms.

SET out your work with accuracy, and the time you will save will bring profit as well as credit to your employer and yourself.

The Draft of Chimneys.

AT the closing meeting of the British Association Lord Rayleigh read a paper before the mechanical section on the effect of wind on the draft of chimneys, based upon experiments made with tubes and a fan driven by hydraulic power. He stated that a horizontal wind would usually promote a draft, except in cases where the chimney opened out upon a large expanse of wall, and so was indirectly affected. The cure in this case was to carry the chimney higher. When the wind was inclined downward to the chimney at an angle of thirty degrees and upward, there was a down-draft, and the maximum up-draft was produced by wind inclined upward at about the same angle. The simplest thing to prevent wind blowing down a chimney was to erect a T-piece on the top. In that case a vertical or inclined wind favored the draft, and the effect of a wind blowing through the T-tube was practically nothing. Mr. Park Harrison suggested as the only real remedy an increase of draft. If all the chimneys in a house could be made to open into a common cloaca, a down-draft would hardly ever occur.—*The Builder.*

Action of Open Fires.

THE way in which an ordinary open fire-place acts to create circulation of air in a room with closed doors and windows is as follows: The air is drawn along the floor towards the grate; it is then warmed by the heat which pervades all objects near the fire, and part is carried up the chimney with the smoke, whilst the remainder, partly in consequence of the warmth it has acquired from the fire, and partly owing to the impetus created in its movement towards the fire, flows upward towards the ceiling near the chimney-breast. It passes along the ceiling and, as it cools in its progress towards the opposite wall, descends to the floor, to be again drawn towards the fire-place. It follows from this that with an open fire-place in a room the best position in which to deliver the fresh air required to take the place of that which has passed up the chimney is above the projecting chimney-piece and at any convenient point in the chimney-breast between the chimney-piece and the top of the room, for the air thus falls into the warmer upward current, and mixes with the air of the room without perceptible disturbance.—*Furniture Gazette.*

TO REMOVE bolts that have rusted, without breaking them, the most effectual remedy known is the liberal application of petroleum. Care must be taken that the rusted parts are reached by it, and some time must be allowed to give it a chance to soften the layer of rust before any attempts are made to remove the bolt.

TO CLEAN MARBLE.—Chalk, powdered, and pumice stone, each one part; soda, two parts. Mix with water. Wash spots, then clean and wash off with soap and water.

San Francisco Architectural Publishing Co.

JAMES E. WOLFE, GEO. H. WOLFE,
EDITORS AND MANAGERS.

Rooms 11, 12, 13, No. 240 Montgomery Street.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, per square, each insertion	$ 2 50
Back " " " " "	2 00
Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each Subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is 1 inch in length by width of the column. When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

Bound Volumes of this Journal.

Bound volumes of 1879, 1880, 1881, and 1882 (in one book) complete, with all ads. and covers removed, will be sent to any address upon receipt of $8.00.

Bound volumes 1881 and 1882, each $2.50
" " 1880 (only a few left) $2.00

In 1880 the subscription price of this journal was only $1.50, and we have put the price of bound volumes accordingly.

Volumes of 1882 and those containing all the numbers from the first issue, bound in one volume, are supplied with a full index.

Any one failing to receive a complete index will be supplied by sending a postal card to this office with their address.

A Building Boom.

COMPARISON OF THE FIRST SIX MONTHS OF 1883 WITH THOSE OF OTHER YEARS.

THE present outlook of building operations is such as to gladden the hearts of every material man and property owner on the coast. At the beginning of the year we remarked that the building interests were alive to the grand future of this city, and that this year would be one of the most prosperous known in its history. We do not wish to be known as prophets. The very hackneyed phrase—too common in newspaper literature — "we prophesy an increased activity" &c., has never appeared in our building reports.

All the deductions and intimations of future business in building circles have been given after very careful inquiry among our business men and architects. To the latter class especially are we indebted in a great measure for so successfully placing before our readers, almost a complete record of buildings as they have been erected. And we take this means of publicly thanking the architects for their kindness in giving us the various items to enable us to present such results as we do in this issue.

We repeat again what we have said before, that we will not report a building until the contract is let. Our relations with architects are such that we hear, and in fact know of many buildings that "are in the market" long before the contract is signed. It would be manifestly unjust to the architect to report such items until everything is settled.

We find that in the first six months of 1882, there were reported of building improvements—brick, frame and alterations—

281 BUILDINGS, OF THE VALUE OF $1,238,910.

For the first six months of 1883, we find the total number to be

424 BUILDINGS, OF THE VALUE OF $2,464,898.

This is truly a good showing, and the result appears more remarkable when we take into consideration the fact that, so far, this year, there have been but few large single buildings erected. We have had no Phelan Blocks, Sugar refineries, Eagle Blocks, etc., to swell the grand total. From the first of the year there has been a steady demand for good dwellings, and as yet it is unabated.

Some of our cotemporaries—daily papers—a short time ago laid great stress upon the fact that the erection of so many buildings for "flats" would cause a great many to desert the old-fashioned buildings for the more modern dwellings. This, they argued, would result in a great many idle non-rentable houses on account of their lack of modern conveniences. These after being idle awhile would be rented for much lower figures, and thus cause parties to move from the "flats" to their old residences again.

The journals indicated did not give the property owners the credit to which they were entitled. In numerous instances, as soon as a tenant left one of the old-fashioned dwellings, the landlords immediately went to work renovating and re-modeling, and introducing the "modern conveniences" necessary. And to-day there are but comparatively few vacant houses to be had.

The amounts given for this year so far, are almost 50 per cent greater than for the whole year of 1880.

Architects generally are busily employed on sketches, plans, etc., for these patrons, many of whom are at the springs. After the 4th of July we may look for a steadily increasing business. Good workmen are now scarce, and the "boom" may receive a set back by the high price of labor and the disposition shown by the material men to add on every cent possible to their goods, whenever they think the public will submit to the imposition.

Still Onward and Upward.

WE are compelled to again enlarge this journal to meet the requirements of those who are gathering in the golden shekels by giving to the general public a full description of their wares through our advertising columns. Several ads. have been sent to us from the East during the past month, which we were compelled to decline. We do not insert any except those that relate strictly to the building interests and the furnishing of houses after completion.

We would also notify parties sending us ads. that unless their order is accompanied by a deposit, or suitable references given, we cannot insert the same. This rule is imperative.

During the past month we have enlarged our editorial corps, and it will be our aim, in each issue, to present a journal, the peer of any now printed. Further improvements are in contemplation, and we will use our best endeavors to merit the confidence reposed in us, by establishing an architectural and mechanical journal that will of necessity be found in the offices and dwellings of every property owner, architect, contractor and the trades generally.

A PORTABLE ice-freezing house is the subject of a patent granted to Mr. A. Von Krause, of West New Brighton, N. Y.

Our Original Table of Steel Square Mitres.

WE prepared, arranged, and published in the June No., 1882, of this Journal an original article, accompanied with an illustration plate, giving the figures on the steel square by which the various mitre cuts from a triangle to a 16-side polygon could be made. This table we found reproduced in a late number of the *Carpenters and Builders Journal* without credit, and afterward in the *Builder and Wood Worker* with credit given to the first-named journal. That the table in question was *extracted* from our columns admits of no question as it cannot be found in the same form and with the same figures in any book extant. We claimed no new discovery in mechanical science, but did and do claim the tables as worked out by us to be original and certainly convenient to the mechanical portion of the readers of this journal, as well as the journals which have copied us.

We challenge the editor of the paper mentioned to refer us to a page in Nicholson, Hatfield, Bell, Hodgson, OR ANY OTHER AUTHOR, which contains the information we claim as being the first to produce in the manner we did.

In our April issue we noticed the plagarism provoked by the fact stated that the *Builder and Wood Worker*— a journal edited by competent and intelligent gentlemen, who, realizing the value of the table, and knowing it to be of recent originality, having never before seen it in print—gave credit to the journal from which they copied—hardly an excusable error, as the *Wood Worker* received the article in question about the same time as the other journal did through the columns of this journal, and might have given credit where credit is due.

In our April No. we noticed the facts in issue, and charged unfairness on the part of the *Builders Journal*, at which the editor takes exception, and by vagaries seeks to make it appear that we are not entitled to special credit in the preparation of an article, which simply uniforms certain valuable and familiar facts, which for long years seems to have remained stowed away in the great store-house of our contemporary's unrevealed intelligence and knowledge—unpossessed of interest or importance sufficient to justify their publication, until WE arranged and produced them in form rendering them worthy of reproduction.

If our table of "MITRE CUTS" were old and familiar, how is it they have never appeared in print, prior to publication of this journal? And how happens it that they were so speedily reproduced in the journals named, after we published them? The attempt of our contemporary at sarcasm is very vague and feeble, and by no means disposes of the fact that the article in question was *extracted* from the columns of this journal without proper credit.

Our worthy brother editor has placed himself in a peculiar position. He intimates that the m tres in question were made according to the figures given TWENTY YEARS AGO. And yet in a book published by him only FIVE YEARS AGO he does not give the information in question.

Again, in his own book, he gives the figures on the square necessary to use to form an octagon as 7 to 17. Passing strange indeed it seems to us, that an editor TWENTY years ago should know the figures as WE published them, then writes a book only FIVE years ago, giving the figures as above, then in 1883 copies our figures and gives them as they ought to have appeared in his own work—7⅛ to 18. There is not a mechanic worthy of the name, that does not know that 7 to 17 will NOT give the octagon mitre. And the deduction is fair that if the editor mentioned does not know what figures will produce the octagon mitre, he may not know what will produce the more simple mitres and certainly cannot be expected to understand those for the more difficult cuts. However, he may have learned, since the publication of his book in 1878, the proper figures on the square for an octagon cut, which he will find correctly given in our table, together with a number of other cuts, to which he may not have given the necessary "labor and study" to become familiar with. Other examples may be quoted from the book mentioned to illustrate the danger of living in glass houses and attempting to throw stones.

The concluding paragraph from our contemporary's article deserves no notice from us as it does not state facts as far as either that journal or ourselves are concerned.

Mechanics' Lien Law.

THE following letter was received in time for the May number of this journal, but was overlooked until too late for publication:—

SAN FRANCISCO, April 11, 1883.

EDITORS OF THE CALIFORNIA ARCHITECT —*Dear Sirs:* It would be very useful to many of your readers if you would give in the ARCHITECT a statement of the law at present in operation in California in the matter of mechanics' liens on buildings. These laws have been recently changed, and there seems to be at present much doubt among persons interested in the subject as to how the law stands. Yours truly, A SUBSCRIBER.

"A Subscriber" is in error about any change in the lien law by recent legislation. It stands now just as it did in 1880. In the July number of this journal for that year there will be found, page 64, a full digest of the law as it then stood, and as it now stands, making owners liable for all claims and demands for material furnished and labor performed, without regard to the sum of contract. There is at present a case before the Supreme Court of this State, involving the question of owners' liabilities beyond the contract amount. Should a decision be rendered upon that point before our July number is issued, we will give it in this connection.

IT should always be carefully borne in mind that in bare wires, out of doors, erected for the purpose of conveying electricity, there is always more or less danger to person or property.

The Mysteries of Metals.

NOTWITHSTANDING the wonderful progress, says an exchange, that has been made during the last half-century in the construction and working of the useful metals, there is yet a vast deal to be learned. The metals when pure are commonly supposed to be simple elements, yet there are some reasons for supposing that it may be proved that at least some of them are compounds. Even the great Faraday gave utterance to the thought that the dreams of the alchemist might yet be realized—that gold and other metals might be found to be compounds, and that means might be devised whereby those compounds might be separated and afterwards so differently reunited that the baser metals might be converted into precious. The changes which are wrought in iron and steel by converting, annealing, and hardening processes are far from being understood by the most advanced metallurgists of the present day. The mysteries of hydrogen gas and its intimate relations with iron are as much a puzzle as they were fifty years ago, and the theory advanced by Graham, that hydrogen is a metal, is still maintained by many chemists.

It is only a few years ago that absolutely pure iron became known to scientists, and it is now shown to be a metal almost as "unstable as water," and still found in the laboratory as a great curiosity. What had previously been known as a pure iron was shown by Jacobi to be a compound of iron and hydrogen. He first separated the two so-called elements. During the process the iron increased in volume, changed from a dark to a silver-white substance, very ductile, and so soft as to be nearly as readily cut as lead. The experiment proved that hydrogen played an important part in hardening and tempering—as much so as carbon—but how or why none know to this day. It is found that much more difficulty is experienced in rolling and otherwise manipulating gold in a factory where much electricity is generated by the action of machinery than in a room where no machinery is in operation, and where, consequently, frictional electricity is absent. The trouble is manifested in a disposition of the edges of the plates of thin bars to crack. Many other peculiarities, already known, might be mentioned, and there is no doubt that closer observation will largely increase the number of curious and yet inexplicable phenomena connected with the working and general characteristics of the metals, both useful and precious.

GREASY COLOR.—The painter is frequently annoyed by having his paint or varnish crawl, or draw up leaving bare spots, when applying it over a painted surface. The cause is what is known as "greasy color," that is, if the paint was not mixed with oil it is a greasy pigment, such as lamp-black—but the most common trouble is too much oil. To overcome the difficulty wash the surface, or simply rub a damp shammy over it, or if it be only a small spot that appears "greasy" blow the breath upon it and the crawling will be overcome.—*Painter's Magazine.*

USES OF THE STEEL SQUARE.

Application of the Steel Square in the Construction of Roofs.

"Construction is the Anatomy of Architecture."

WHEN the term ROOF first became to be used to denote its present significance, we have no means of determining. In the Bible we find the word "housetops" used in many places, and from the description given we infer that the roofs or coverings used were nearly flat, just sufficient pitch being given to shed water. Among some of the oldest ruins now found—those in Bashan particularly—the roofs are almost flat; they were made of large flat stones, laid in a species of cement, and to this day, such was the quality of materials used, that water will run off the parts of the roofs remaining standing, with no leaking between the various stones used.

Other roofs were made of boughs of trees laid close together and covered with earth, the top being of a kind of clay cement, that was impervious to water. These roofs were well adapted also to protect the inhabitants of that part of the country from the excessively hot rays of the sun.

In the building of Solomon's Temple, the small part that was roofed was covered with boards and these with gold and silver. This may be said to have been the first metal roof ever constructed.

FIG. 1

In pictures of "ye olden times" we find the roofs to be of similar shape to our engraving, simply boughs and branches of trees covered with leaves and earth. This perhaps answered for small gatherings. When large parties congregated, the difficulty of getting branches of trees long enough to form a roof of only one pitch, suggested to some one the idea of adding on an addition similar to that shown in Fig. 2.

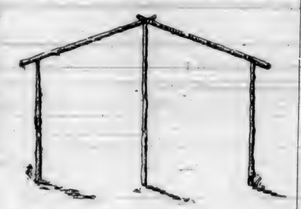

FIG. 2

In this simple manner was formed the grand principles of the construction of roofs. The supports to the ridge necessarily occupied much space, and, being in the way of the throngs that visited the great fairs held in ancient times, no doubt some thoughtful mind conceived the idea of so binding the ends of the boughs together that the roofs were almost self-supporting.

FIG. 3

In an old work we find an illustration similar to Fig. 3. The boughs were crossed and tied together with some material then in use, and a wooden pin being used to further strengthen. Braces were used as shown, and thus a considerable span could be made. This theory of the gradual development of the construction of roofs seems natural. We cannot give the date of this improvement, as the chronicles in reference thereto are very indefinite.

When hewn timber was introduced in the various parts of buildings, the natural genius of the people then in existence, led them to give their roofs all kinds of fantastic shapes, and these crude efforts were seized upon by some of the master minds, and a uniform and distinctive style of architecture was accorded to each. We in our day but imitate our predecessors in the art of improving and excelling the ideas of the generations immediately before us.

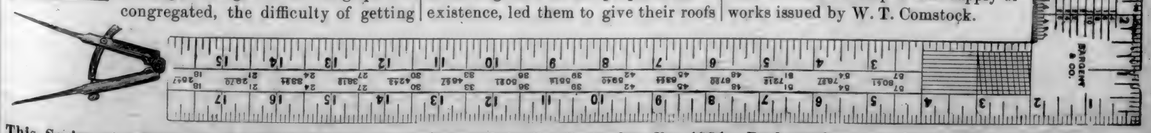
Going back to the time of the ancient Greeks, we find the roofs nearly flat, composed of large marble slabs, neatly grooved together so as to be impervious to water. They did not have the same idea of architecture that was possessed by the stately Romans. An observer justly remarks in regard to the latter, that "I have not seen the remains of any Roman buildings that have not been *roofed* with vaults and arches."

We also find that in the construction of roofs in the Norman and Gothic periods, the *tie beam* is wholly lacking. In lieu of these we find the necessity of using immense buttresses to withstand the immense outward pressure of the roofs upon the walls. Owing to the manner in which buildings are now erected, the *tie beam* is one of the principal factors in a well constructed roof.

The exact period in this world's history when the use of timber for framing roofs became general, is not exactly known. The first authentic accounts place it about the year 1325. From this period we find the roof taking more prominence in the architecture of buildings.

We do not pretend in these articles to give a full and accurate description of the history of the architecture of roofs. We only show how the gradual development of the principles of their construction may have been formed, and the remarks made are only incidental to a discussion of the principles of the scientific framing of roofs.

WE are sole agents on the Pacific Coast for the works published by the Industrial Publication Co. of New York. We also keep a full supply of works issued by W. T. Comstock.



This Series of articles on the Steel Square was commenced in the September No., 1881. Back numbers can be supplied at 20 cents each.

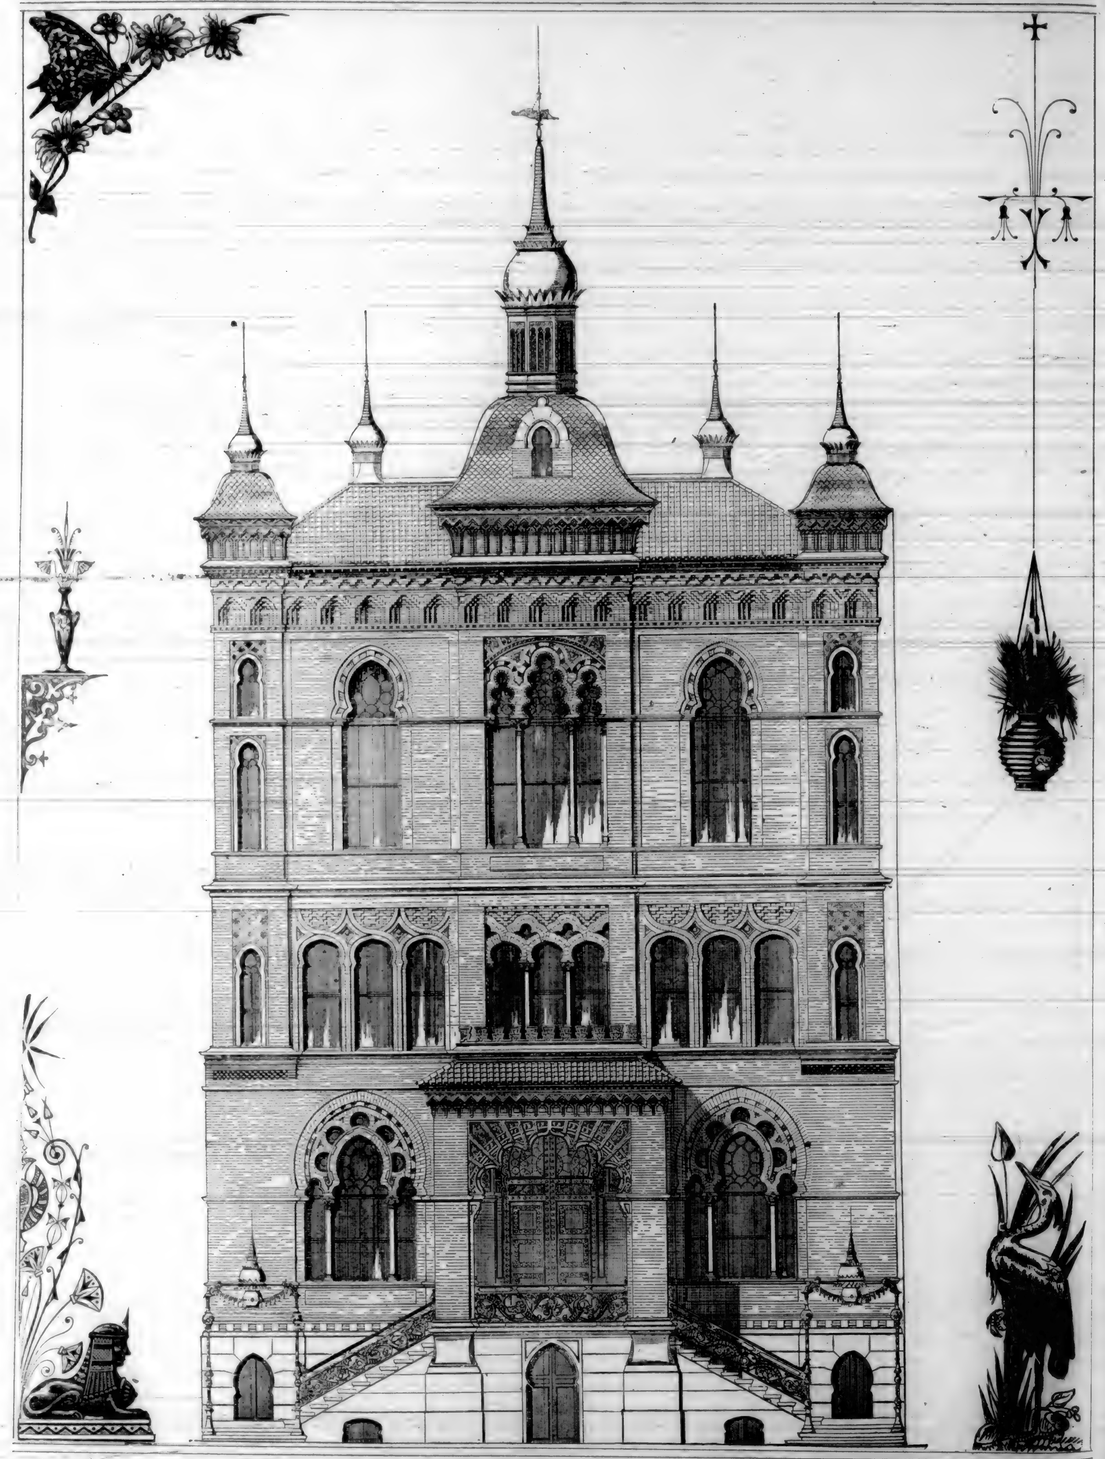


PLATE I.—FRONT ELEVATION OF THE BUILDING FOR THE PROGRESS CLUB OF NEW YORK. Guastavino & Gruvé, Architects.

New York Street Architecture.*

THE MORESQUE.

NEW YORK streets have never recommended themselves for their architectural beauty, and it is comparatively recent that any material advances have been made in the construction and reconstruction of city fronts. The fault has been, I think, with all American cities, that buildings have been put up running about the same size and general appearance throughout an entire block, and each succeeding street a counterpart of its predecessor, the cornice extending along the same sky line, and the brick or brownstone showing no ornament other than the prescribed number of iron sills and keystones, properly painted and sanded. It is true, to some extent, that the cities of Europe construct their buildings with very much this sameness of effect, but it must be allowed that the monotony of the Parisian residence is entirely different to that of the New York dwelling, inasmuch as the French exterior is broken with frequent balconies, with misplaced windows, with a pretentious *porte cochere*, with a profusion of decoration in the stonework, all tending to divert the attention from the point that they are so frequently repeated, and weariness to mind and eye is avoided by the repetition of agreeable details.

The disposition appears to have been aroused now, however, to beautify exteriors, and some of the efforts in this city are noticeable; the universal revival of the Moresque forms in decorating and furnishing has finally affected architecture and that style at present prevails more generally, I think, than any one other. Many of the façades have been constructed of iron, though iron is but little in favor with us. It has its advantages, of course; it may be moulded into a great variety of forms and shapes, restricted only in the feeling that those figures are not to be so clean cut, sharp, decisive in outline, as would be demanded of the same pattern in stone; it is admirable for those large, indefinite-appearing patterns where the details are not expected to be studied, and a little clumsiness is looked for in the figures; yet it is capable of beautiful effects. Nothing is finer than the sweep of a delicate, airy arch, apparently so fragile and weak, whilst capable of bearing the most substantial sort of a roof or supporting thousands of glass sashes. All these merits and most desirable qualities are recognized by our architects, though, notwithstanding them, they have emphatically and unmistakably discouraged the further or increased employment of iron, and its pretensions as a constructive element are ruthlessly and eternally doomed. To many its purposes seem to be so entirely distinct from architectural ends, that they are persuaded against its use as an architectural adjunct. Certainly in its natural condition as a metal, it would never be exposed in the façade of a building; it is, therefore, painted, and grained, and sanded, until it looks like absolutely nothing upon the face of the earth that is supplied by nature.

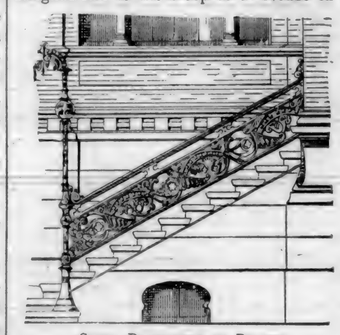
One great merit of iron is its entire freedom from the restrictions of style or form. Stone and brick have been used in every conceivable manner; if one seeks a renaissance home, and intends building of stone, the model for that stone renaissance dwelling is forthcoming at once; if a Moresque residence is desired in brick, the most elaborate example of brick Moorish construction is at hand. But the wildest architect of the crazy epochs of the renaissance never thought of iron; the suspicion of using any metal, excepting for decorative purposes, never occurred to the designers of the Alhambra. Thus our young architects have now an entirely new material, from which they can make entirely new styles; they run no risk of inconsistency or anachronism; so far as precedent goes, or is concerned, a twelfth century gargoyle would set admirably upon the volute of a Corinthian capital, or the corner of a Tuscan roof—provided it be of iron. Neverthless it is not popular, and while we have a number of buildings with iron fronts, I doubt very seriously whether they will ever attain popularity or even general approval.

In the Moorish style much scope is given to the use of iron, and the majority of buildings of this order put up of late, are made from this material. Some of those upon Broadway are certainly rich in their effect, and altogether more gorgeous than they could possibly have been made had their construction been of brick or stone. One large Moresque structure is particularly noticeable, having its front divided into the three sections of an inside wall space, dado, center and frieze; the line of the bottom of the second story windows marks the termination of the dado, the center space or wall proper extends to the fourth story where the frieze commences. The colors are of an elaborate and showy character, but well arranged; the lower portion is darker than that above; the wall space shows a flat color with a light frieze.

It is a question whether these buildings can be said to reflect the Moorish design; the principles of the order are not followed out, and the coloring, as now done, is at variance with good taste; such buildings are rather the combination of a variety of styles, a feature that is very often indulged in when one wishes to revive an ancient form and feels it should have some of the modern improvements incorporated with it. This disposition is sometimes an unfortunate one, inasmuch as it is seldom qualified, or rather allowed, to develop an improvement, but more often detracts from the appearance, and by combining differences, frequently serves to depreciate their beauties. There is no objection that should stand in the way of our artists or draughtsmen making use of all the features that have been utilized heretofore; but by all means let those features be the best attainable, and if it is desirable to enter a Romanesque building through a Grecian portal, let it be done in fact and in spirit, and have that portal purely Greek, not a mongrel admixture of nothing in particular.

The best example of recent Moorish construction shown in Yew York, I make the subject of my illustration, giving the entire front, and small detail reproductions of windows and balustrade. It is Moorish in every line and every detail; the architect has followed his model to the letter, and avoided everything in the shape of modern innovations, from the balls upon the minarets, which are just of that rotundity peculiar to this order, and slightly smaller than the swell which distinguishes Jewish architecture, to the pattern of the bronze railing upon the stoop, all things are moresque. There is but one divergence from the antique, and that is the use of iron roofing and terra cotta trimmings. This fault, however, is so slight that we might overlook it.

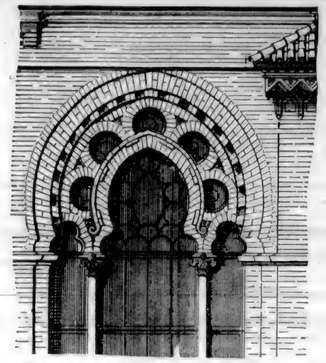
The illustration, plate one, page 88, shows the façade of the Progress Club building, now in course of construction on 59th Street; the architects are Mr. Rafael Guastavino, a Spaniard, who has made New York his home, and Mr. F. Gruvé, who have had the good fortune to design several interesting and characteristic buildings. Plans for the Progress Club were submitted in an advertised competition, and was participated in by some of the very best of our local architects. The building is entirely of brick, fifty feet front, one hundred and two feet deep, eighty-eight feet to the top of the center tower, and will cost, when completed, $90,000. The curiously designed rail to the stoop is of bronze in its



STAIR BANNISTER IN BRONZE.

natural color, with a profusion of detail that may be more clearly traced in the individual illustration given of it. The entrance door is heavy oak, studded with bronze nails, and having a fanlight of colored glass; above the balcony-like vestibule at the entrance is a projecting cornice formed of tiles or clay pipes. The intertwining band over the windows, it will be noticed, is arranged so as to run around, over and under itself, in a true Moorish fashion. The roof and the spires are covered with iron shingles and tiles, painted being in imitation of cotta, the appearance the same, with the advantages that iron is much cheaper and of course more durable, if the difference in this latter quality was thought worthy of consideration. The balls are to be gilded, and the leaf-like ornaments about their base and crown to be bronzed.

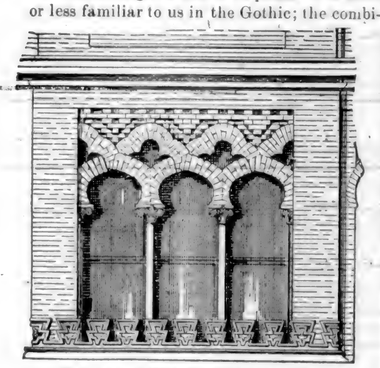
* This article and the illustrations were prepared expressly for this journal by A. Curtis Bond.



WINDOW OF LADIES' RECEPTION ROOM.

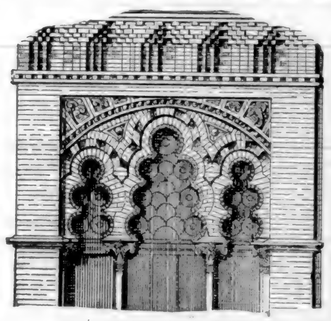
All the decorative work over the various windows is done in glazed bricks.

The contours of the arch as a principal outline is peculiarly distinctive of the true Moorish, though in one of its phases it is more or less familiar to us in the Gothic; the combi-



CENTRAL WINDOW OF BILLIARD ROOM.

nation of square and arch is another characteristic that is calculated to add the semblance of weight to a construction otherwise fragile in its appearance. The horse-shoe arch was popular with the Moorish architects in Spain, and it may be seen



CENTRAL WINDOW OF CONCERT ROOM.

in the great majority of their buildings. This arch was later broken into an infinity of smaller curves or horse-shoes, and made to intersect the sides or spring from the center of other smaller arches, and thus was shown a succession of scollopings such as may be noted in the upper central window of our building.

While I admire the Moorish designs, and delight in its appeal to my imagination, I am tempted to ask whether it is adapted to our customs and this locality; it is emphatically the style of romance and of pleasure; it enlivens the mind and inspires the thoughts; it is picturesque and striking; its interior especially encourages the dreamer and the imaginative; and how at variance is this with our dull, prosaic wintry East, where we are having snow-storms in May, have always had rectangular blocks of cheerless dwellings, all of them monotonously alike, streets solidly paved with stones that even John Ruskin would despair to make esthetic or artistic, and our amusements, entirely of an artificial character, graduating from an Academy of Music down to a beer saloon; Central Park, hedged about with "regulations that keep visitors upon the stone-paved walks and forbid any incursion upon the grass; no zoological garden, no Louvre, no art gallery, where one may instruct as well as amuse oneself; nothing, in fact, that will offer an hour's enjoyment without the imaginative destroying element of an entrance-fee, and the pleasure-killing surveillance of one of our interesting Puritanical laws.' In this community, with such accompaniments, an architecture or a sentiment that breathes of the poetry or the romance of life, seems very much out of place.

S. F. Chapter. American Institute of Architects.

THE regular monthly meeting of this Chapter was held on Friday evening, June 1, John Wright presiding. Reports on the classes established by this Chapter were received as follows:—

F. Marion Wells reported that his pupils were doing finely. Each one was possessed of an ambition to excel and stand at the head of the class. This was proven by the fact that the pupils were always on time to commence their work at the appointed hour and endeavored to carry out the instruction given them to fully meet the views of their teacher. Strict discipline was maintained; one of the pupils had shown neglect to his duties and was promptly dismissed. G. H. Sanders reported the progress of his class was better and better. After consultation with the members of his class, it had been decided, next season to institute classes in *Practical* instruction in carpenter yplumbing, etc. It was the aim to make the students thoroughly conversant with the *practical* work of every branch of the profession. Mr. Pissis' class was also improving. It was decided that owing to the regular time of the meeting of this Chapter next month, coming so near the 4th of July, that the meeting be postponed until the regular night in August, thus giving the members a chance to go in the country if so disposed.

A New Fashion that is also an Improvement.

ALTHOUGH it is sometimes difficult to draw the line sharply between a modern improvement and a modern fashion and to distinguish readily one from the other, there is still a great difference between the two, a distinction and a difference which a true philosophy would doubtless enable us to discover at all times. Unfortunately we cannot always stop to philosophize hence the mortification and defeat that are sure to follow when we find our dearly bought "improvements" turning into the ashes of a by-gone fashion. As a rule we must learn by an experience both painful and expensive, whether our condition is really improved by the new styles that are constantly intruding themselves in the countless details of building and furnishing our houses.

Certainly one of the most pleasant and attractive of the later fashions is that of arranging the plan of a house so that the entrance "hall" shall be something more than a long narrow passage into which the stairs obtrusively crowd and which contains of movable furniture at most one or two straight backed chairs and a "hat tree," a passage which is never dreamed of as valuable for any other purpose than a means of access to the inhabitable regions beyond. This fashion is something more than a fashion, it is a genuine improvement. Even so slight a change as to increase the width of the narrow way, making a little reception hall no more than a dozen feet square, is a great gain since the space so taken is just as valuable for entrance purposes and is also available for social use, either by itself or in connection with some adjoining apartment. The hall of our sketch is not merely a reception room, but with its fire-place, its broad light at either end, its raised gallery for music in case of a dance or a private musical entertainment—the gallery being a part of the staircase that climbs by easy stages to the second floor—with the wide entrance to the dining-room at the left, and to the parlor and library on the right. With all these conspicuous and comfortable features, it is the very center and heart of the home. The sense of cordial hospitality and welcome which one experiences on entering such a hall as this can never be imparted by one of the straight-and-narrow, formal and impossible-to-be-pleasantly-furnished halls that belong to the old-fashioned houses. —*The Builder.*

HEAVY damages have been awarded by a Chicago jury to a tenant against a landlord for misrepresenting the condition of the plumbing and sewerage of a residence. The tenant took it intending to keep a boarding-house, on representations that it was all right, but after moving in the furniture, found the sewerage in bad condition, and the hot and cold water faucets without pipes to supply them with water. The house was not fit to live in; the tenant removed his furniture and brought suit against the landlord for expenses incurred and other damages, and recovered $3,500.

☞Architects, Contractors, Carpenters, and Mechanic generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas, send us a sketch of them and we will make the cuts.

AFTER the dust has been thoroughly beaten out of carpets, and they are tacked down again, they can be brightened very much by scattering corn meal mixed with coarse salt over them, and then sweeping it all off. Mix the salt and meal in equal proportions.

WHEN you have the wood-work in a room painted, it is a good plan to have about two inches of the floor painted also; have the paint the same color as that of the base board; then if, when changing carpets, the carpet will not come close to the wall, the little space left will not be so unsightly.

AN improved automatic guard for protecting the hatchway of elevators has been patented by Messrs. Joseph Byers of Newtonville, and George Taylor, of Everett, Mass. This guard is pivoted to a post, and it is raised or lowered automatically by the movement of the platform when lowered. The free end of the rod rests in a receiving jaw or loop, one part of which is free is actuated by a spring while the other part is fixed. Both parts are provided with elastic cushions which receive and prevent the guard from rebounding.

New Publications Received.

Cottage Homes.—
A NEW work, W. T. Comstock, publisher, has made its appearance. It consists of 44 large quarto plates in the styles of architecture now prevalent in the Eastern States. There are many illustrations of low-priced cottages, and this fact should cause a good sale among the interior towns. Most of the designs given are for country cottages, varying in cost fron $800 to $5000. We have received a large number of this new work, and will forward them to any address upon receipt of the publisher's price, $5.00.

Street, Store, and Bank Fronts.—
This book contains 34 designs for street fronts for dwellings, stores, and banks. Details are also given. All the designs, etc., are drawn to scale. Price, $4.00

Stables, Outbuildings, and Fences.—
24 plates, wooden and brick buildings, with details, showing sixteen plates, elevations and views of stables, outbuildings, and fences, and over one hundred miscellaneous details. Price, $4.00.

Cottage and Villa Architecture.—
This large work contains plans, elevations, views, sections, and details of low priced, medium and first-class cottages, villas, farm houses, and county seats, with specifications. All drawings to scale. Will be sent to any address upon receipt of $8.00.

Artistic Homes.—
44 full-page illustrations, by A. W. Fuller, Price $4.00.

Modern House Painting.—
By Rossiter & Wright. This is a very useful work as it exemplifies the Eastern ideas as to how a house should look after being finished. 20 large colored lithographic plates. Price, $5.00.

Mechanics' Institute Exhibition—1883.

THE preliminary announcement is made by the managers of the Institute that the "Eighteenth Industrial Exhibition" will be opened on the 11th of September next, to close October 13th. The exceptionally promising condition of things in general, in this city and throughout the State, are in themselves sufficient to justify the course adopted by the management of the Institute. The grain fields of California never promised a grander return from the seed sown than that which this year cheers and gladdens the hearts and brightens the hopes and prospects of those who plough and sow that they may reap, while those who buy and sell or grind the golden grain, are made happy in anticipation of the splendid results which are assured by the harvest of 1883. Nor is this happifying feature the only hope and boast of our favored State and coast, for the yield from millions of trees and vines was never better, nor ever did the golden rays of prosperity shine more brightly and universally than at the present time. None need be sad, nor any feel that their lot is hard, except those who fail to comprehend and grasp the splendid possibilities within the reach of all who strive to profit by the abundant advantages this year so profusely distributed everywhere. And if the management were all pious and devout men, they would scarcely perform their duties well, did they not add another feature to their programme, and suggest, if not ordain some method by which, amid the general rejoicing, themselves and their patrons might be led to acknowledge the goodness of that hand which has so bountifully poured its blessings upon us as a people. Ingratitude becomes not those who receive good things, and if forgetfulness of heaven's bounties by all classes be returned for the beneficence bestowed, need it be wondered at should future years bring us dry and parched lands, and stunted and desolating harvests?

In addition to all this, thousands of worthy and honorable men from abroad are expected to visit our city as Knights Templars, and it is well that nothing should be left undone to enlist their good opinion of us as a people, and make it possible that they return to their homes with kindly remembrance of the good times enjoyed by them in San Francisco, and with the fixed conviction that San Francisco as a city, and California as a State, are entitled to a high rank among the cities and States of our glorious Union.

As encouragements to exhibitors, gold, silver and bronze medals, diplomas, etc., will be awarded. Power will be provided for driving machinery, and all usual facilities afforded to give motion to the numerous inventions, and demonstrate the practical working of devices requiring motive power.

Natural products—cereals, fruits, vegetables, etc., will be allotted their proper share, and for the first time in several years, a Mineralogical Department will be instituted, showing samples of the most important ores and minerals found on the Pacific Coast. The Art Gallery, Horticultural Department, and all others that will add interest to the exhibition, will be provided for, and the management will aim to make the exhibition of 1883 equal, and as far as possible, superior to those of all preceding years.

Improved Process of Making White Lead.

IN the United States the manufacture of white lead is conducted according to the Dutch method. Plates or gratings of lead are exposed to the fumes of vinegar, in vessels set in tan, or stable manure, which acts as a hot-bed to warm and volatilize the vinegar. As the lead is corroded, it becomes covered with the carbonate, which is removed with hammers and ground. The process is tedious, slovenly and unhealthy, and many attempts have been made to improve it, but none of them have yielded a product equal to that which results from corrosion. Microscopically examined, the carbonate of lead formed upon the metal, is found to consist chiefly of minute crystals which are hydrated, laminated and transparent. These are mingled with a smaller quantity of exfoliated particles of the carbonate, which are opaque. These particles, it is claimed, impart to the white lead its remarkable power of resinifying oils, as well as what the trade calls its body, *i. e.*, its property of completely covering objects painted with it. By the new process workmen are not required to detatch by hand the carbonate from metal which remains uncorroded, and the product is said to consist almost exclusively of the valuable opaque particles. To effect this, the lead is first brought to the porus or spongy form, by which the surface, exposed to the slow carbonating process, is enormously enlarged, the thin mass being seemingly composed of open interlaced fibres. This is put in a close chamber, and there exposed to a mixture of atmospheric air, carbonic acid, and the vapor of acetic acid. The carbonic acid, generated by combustion, is cooled and purified before it is driven into the chamber. The air passes in warm, and care is required to maintain the proper degree of moisture. The carbonate is the shape of the metal upon which it is formed, and the material is not removed until the corrosion is complete.—*Mining and Scientific Press.*

THE bee has long been a type of the industrious worker, but there are few people who know how much labor the sweet hoard of the hive represents. Each head of clover contains about sixty distinct flower tubes, each of which contains a portion of sugar not exceeding the five-hundredth part of a grain. Some patient apiarian enthusiast, who has watched their movements, concludes that the proboscis of the bee must, therefore, be inserted into 500 clover tubes before one grain of sugar can be obtained. There are 7,000 grains in a pound, and as honey contains three-fourths of its weight of dry sugar, each pound of honey represents 2,500,000 clover tubes sucked by bees.

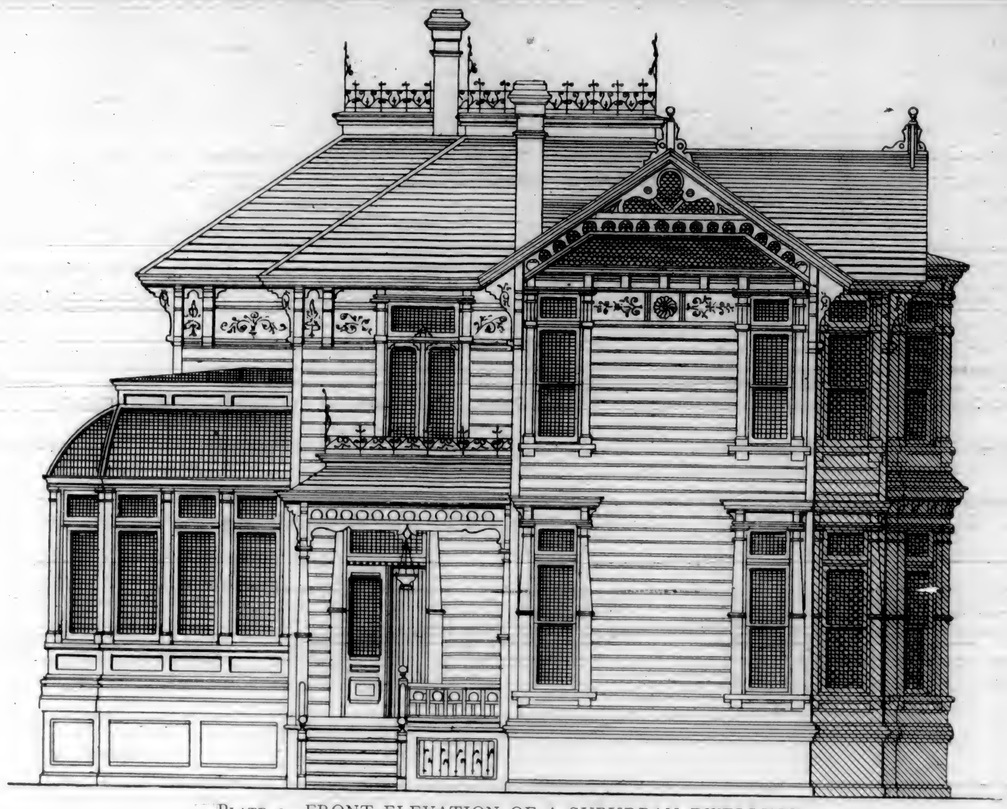


PLATE 2—FRONT ELEVATION OF A SUBURBAN DWELLING.

Will be Back in a Few Minutes.

MECHANICS should remember that "time is money." We have been very forcibly reminded of this old maxim many times since the beginning of the year. Our business relations with contractors, tradesmen, etc., are such that we have been compelled to call or send to them in regard to many things, owing to the great activity now prevailing in building circles.

The sign at the heading of this article has met our vision many times, and we earnestly request all those who of necessity have to be running in and out in order to attend to their business, to change the character of the words so as to read, "9:30. will be back in—minutes," filling the blank with the number they honestly think they will be away. A person calling will then readily understand about the time to expect to meet one at his business. Or the sign may read, "Will be back at—o'clock," filling the blank with the hour. This may seem a trivial subject to some, but to any one whose time is valuable, it is very important to know just when to meet one with whom you may have business relations.

A short time ago we wanted a carpenter to attend to some work. Our boy was sent to his shop, and in half an hour came back with the information that on the slate was, "Back in five minutes." He waited three times that length of time and then returned to the office for instructions, having first written on the slate, "Call at — office." Two hours rolled away and still no carpenter. Being in a hurry we obtained a man at another shop, and after agreeing upon terms, we were startled by the first man sent for rushing breathless into the office. He was, however, too late, and upon conversation with him, we found that he had lost another job the same week by his sign disappointing those who would willingly have waited a day to secure his services, but felt aggrieved at calling twice for nothing, with a sign staring them in the face. "Back in five minutes." Let all remember that although your own time may belong to yourself, you have no right to cause any one to lose his time, misleading him by a wrongfully written sign. Have the time definitely stated when you will return, and use your best endeavors to be punctual at the time of your own choosing.

THE article on "The Care of Fixtures" (p. 102) should have been credited to the *American Engineer*.

Floors Weakened by Gas Pipes.

A SHORT article in the *Building and Engineering Times*, on the subject of weakened floors, deals very intelligently with the harm that may be done in this direction by careless gas fitters. It is common enough, in cases where a pipe has to be led under flooring and across joists to serve a pendant, for the pipe to be taken straight across the center of the room, and the joists notched about an inch deep all the way. Workmen who do this never reflect on the harm they are doing to the floor, nor do they know that a notch cut out of the top of a joist will seriously weaken it. This at once becomes evident when it is known that the strength of a joist, which is a rectangular beam, is proportional to the depth squared. If, therefore, a groove 1 inch deep is cut across a 7 inch deal, the reduction of strength is not only one-seventh, but a great deal more, in the proportion of 36 to 49, or a loss of rather more than one-quarter of the original strength of the beam. This somewhat startling result is due to the self-evident fact that the upper part of the joist is required to be solid, in order to resist compression, just as much as the lower portion must be capable of bearing tension; and to cut a notch in the top of it is equivalent to removing the substance along the whole length of the joist to the full depth of the groove. This observation only applies to cases where the notch is cut out of the center of the span, which is the commoner practice. There is much less objection to cutting joists close to the end, and thus allowing the pipe to be laid round the room to a point where it can be run to the center between two joists. Or, if this course cannot be followed, the pipe may be safely passed through a hole bored in the middle of the joists. If this is not feasible, the indispensable notch may be cut right down to the middle of the joist, and the pipe thus laid across the neutral line; the space above being afterward filled with a tight wedge which will safely transmit the compressive stress.

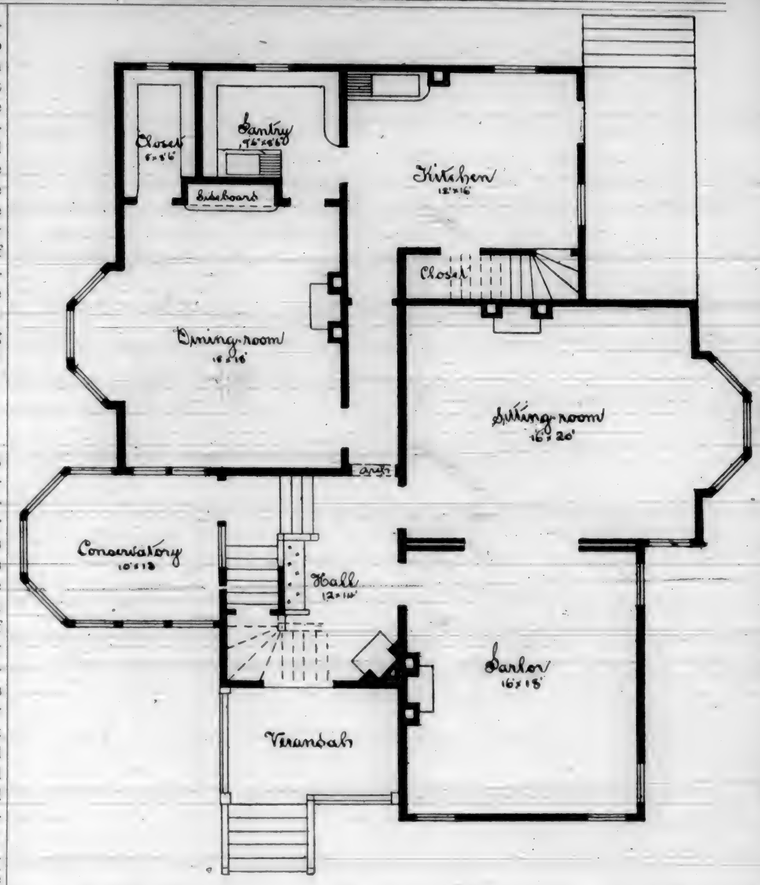

PLATE 3—FIRST FLOOR PLAN OF SUBURBAN DWELLING.

Improvement in Bricklaying.

THE recent suggestion of a correspondent, that instruction should be given at our technical schools in the art of bricklaying is worthy of careful attention. The whole number of brick laid year by year in our large cities is simply enormous, and they go into every class of structure, from the piers of a 9x12 cottage to the walls of a warehouse or factory which in itself may consume millions. In none of these works are the builders likely to put any excess of brickwork, but the workmanship displayed in laying very many of these walls is so extremely imperfect that the question may very justly be raised whether it would not pay better to employ better workmen, provided they could be had, even at higher prices, and cause them to lay thoroughly sound, solid work. If this were done, it becomes a question whether the thickness of the walls in some of these works could not be safely reduced, thus affecting a saving even at the higher cost assumed for the labor of laying.

A serious but common defect in the laying of straight work, especially in long party walls between buildings, is the tendency to put the bricks into the interior of the wall almost wholly dry—that is, with practically no mortar either above, below, or around them. The face-work of such walls is apt to be bad enough, too, for the bed of mortar is usually spread with the point of the trowel, so that the face brick rests only on two narrow ridges, one along each edge. In a large part of such work the end joints are laid with a mere dab of mortar, taken up in the wiping off with the trowel of the bed joint, but this is apt to be not one-third enough to fill this end joint really full.

It would seem an easy thing to secure the proper bedding in the mortar of the interior filling of such a wall, and the filling of all the cross joints, but experience shows that this is a very troublesome thing to secure with most bricklayers. So hard is it to secure this that very many of the walls in stores, or even in warehouses that carry heavy weights, are in a very just sense mere dry walls, possessing little more strength than that due to an absolutely dry piling of the brick between the two face-shells which serve to keep the interior of the wall in place.

It is literally true of a host of these walls, which have the appearance of being solid, that they are thoroughly honey-combed with vacant crevices, and the natural consequence follows that the real strength of the wall is thereby reduced. The strength of a wall of this general character depends upon two things among others, one the absolute weight of the wall, and the other the completeness with which each brick is bedded against its neighbor. Unless this last requirement of perfectly solid work is met, the wall must be clearly more likely to yield when any stress comes upon it from any cause.

Of the need of the best workmanship in special kinds of bricklaying, nothing need be said in this connection, for the call for improvement in plain work is clearly enough marked, and will alone require all the attention and help it is likely to receive in the great crowding of instructing duties that press upon our school officers. It may be said that other things are more needful to be attended to by our young men in schools, and this may be true. At the same time it is true, so far as practice or shop work is concerned, that subjects may justly claim attention which bear most directly upon work which is most largely in request, either in quantities done or in number of places where, if done ill, it needs amendment or correction. If 10 schools should join in sending out next year an average of 10 graduates each trained in bricklaying, even in the limited way proposed, there would be 100 centers of useful influence at once established for securing better work in this respect.—*Mechanics.*

A CROSS-CUT saw invented by an Ohio man has cutting and cleaving teeth of different altitudes, and is provided with longitudinal lines, or indentations, which are parallel with the points of the teeth, and are separated from each other by a space equal to the difference in the altitudes of the cutting and cleaving teeth.

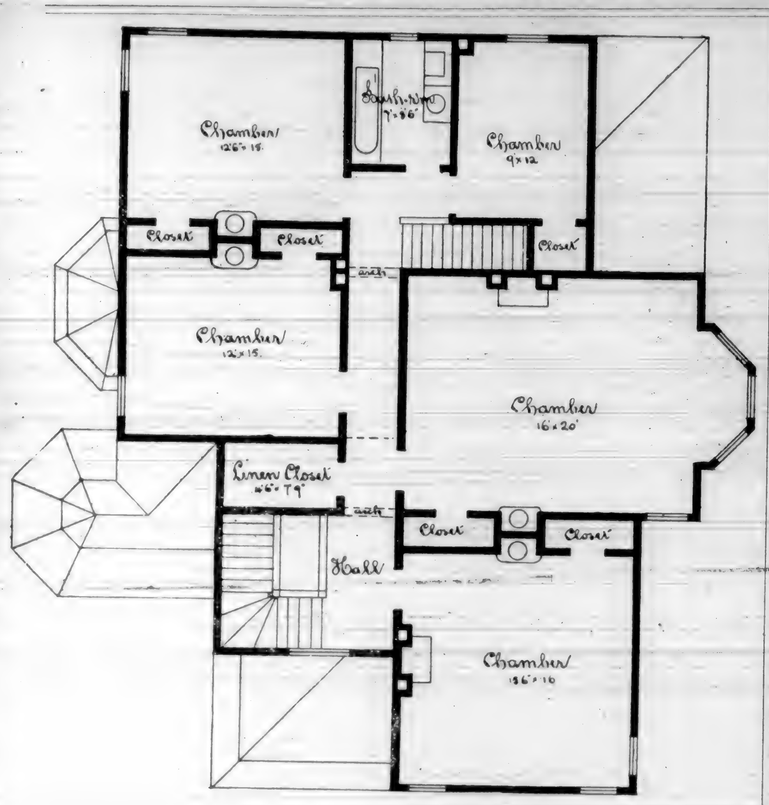

PLATE 4—SECOND FLOOR PLAN OF SUBURBAN DWELLING.

Our Illustrations.

PLATE 1, and the small detail cuts in connection therewith, were prepared expressly for this journal by A. Curtis Bond, from designs of the architects, Messrs. Guastavino & Gruvé. The article was also written by him, and we are pleased to inform our readers that hereafter he will be a regular correspondent, presenting to our readers the latest forms of architecture adopted in the East.

Plates 2, 3, and 4 are the elevation and plans of a neat suburban residence. The plans shown are very explicit and need no description. It can be built for any amount over $5,500, depending altogether upon the styles of finishes used.

Plate 5 is taken from an old work printed 125 years ago. We do not remember to have ever seen the illustration given in any other work than the one from which we have taken it. We have endeavored to give the latest information in regard to the lessons taught by these grand piles of masonry.

Plates 6 to 10 are views and plans of a cheap country cottage. Its cost can be varied from $2,500 to $3,500.

The Decay of Building Stones.

THE practical scientific study of building stones, their comparative merits and their durability when subjected to peculiar local or atmospheric influences, has yet to be made. The failure of some stones to resist fire, discolorations, and the disintegrating effects of the emanations from manufacturing centers, has resulted in their decreased use and the substitution of brick. On the 30th ult., Dr. A. A. Julian, of Columbia College, read the second part of a paper on the "Decay of Building Stones," before the New York Academy of Science. His remarks were based on observations made in this city and adjacent places.

The principle that stones are more lasting when laid on bed is clearly demonstrated in the case of all the building stones. After a structure has been erected a few years, there is no difficulty in dividing the stones laid on bed from those laid on edge, as the laminations in the latter become distinctly marked; and in some kinds this can be discovered immediately after completion, as the more porous layers dry first, thereby giving the stone a striped appearance.

In brownstone a deep decomposition was noted even when laid on bed; when exposed to the heat of the sun, the change is more rapid. The attack of the destroying agents is favored by imperfect jointing, which opens a back entrance. The discoloration in Nova Scotia sandstone might be prevented if the surfaces were vertical and placed out of reach of dripping. It is too soft for lower portions of buildings, and receives and retains the street dust. Ohio sandstone resists our climate well, and when used in Western cities is discolored but not disintegrated. There are but few limestones in the city, and the decay of Westminster Abbey, London, should warn us of the danger of using fine grained limestone until we are satisfied of its durability in this climate. The decay of marble is first shown by its becoming pitted; those set on edge show the more rapid decay. Granite shows pitting, the hornblende being first attacked. The south and west side of the Tombs show decay, while the other sides are intact. The sides affected are exposed to the sun's rays.

Dr. Julien came to the following conclusions in regard to the life of stones, defining life as the period during which the stone presented a decent appearance. Coarse brownstone, best used out of the sun, from five to fifteen years. Laminated fine brownstone, from twenty-five to fifty years. Compact fine brownstone, from one to two centuries. Nova Scotia stone will probably last from fifty to one hundred years. Ohio sandstone, the best of the sandstones, one hundred years. Caen stone, from thirty-five to forty years. Coarse dolomite marble, forty years; fine marble, sixty years; pure calcareous marble, from fifty to one hundred years. Granite from seventy-five to two hundred years, according to variety.

Bluestone is as yet untried, but will prove a good building material. Some of the best building stones in this country have not yet been brought to this city

Some of the causes that produce decay in stones are, first, solutions and hydrations of the stone and the heat of the sun.—*Scientific American.*

Chinese Customs.

THE Chinamen seem to be our antipodes in customs as well as geographically. In matters of dress they finish where the rest of mankind begin. His waistcoat is outside his coat, and his drawers outside his pants. We blacken our shoes; he whitens them. Our ladies compress the waist, theirs the feet. Our women wear long dresses, theirs long sleeves. In China the men carry the fans, and the women wear the trousers. In eatings, their customs are in striking contrast with ours. We have a soup as a first course and dessert at last: they have dessert at first and soup at last. They ignore knife and fork and spoon, and eat with two "chopsticks," both held in the right hand. They abominate beef, milk, butter, and cheese; but eat puppies, cats, rats, birds' nests, sharks' fins and snails.

With us the right hand is the place of honor; with them it is the left hand. In dating letters we place the year last; they write the year first. Instead of saying "northeast" or "southwest," they say "east-north" and "west-south." They always speak of the mariner's compass (their own invention) as pointing to the south. Here, a mother shows her affection for her child by kissing it; a Chinese mother smells of it. We locate the intellect in the brain; they in the stomach. We pay our physicians when we are sick; they pay the doctor while they are well, but as soon as they get sick the pay stops. Here, men kill their enemies in revenge; a Chinaman gets "sweet revenge" by killing himself. They mount a horse from the right side, and when they want him to go they say "Whoa!" The men ride sidewise and the women astride. We use lanterns on a dark night, they carry more lanterns at full moon than at any other time. We place a candle in a candlestick; they put the candlestick in the candle. Their detectives sound a "tom-tom" at night to give thieves and rogues notice of their coming. We ride in railroad cars, they in wheelbarrows. We draw canal boats with horses; they with men. We sell wood by measure, they by weight. We vaccinate in the arm; they in the nose. We use a soft pillow, they a block of wood. Our store signs are horizontal; theirs are perpendicular. They launch ships sidewise, ring bells from the outside, and actually turn their screws in the opposite direction from ours.—*Christian Advocate.*

To construct a well-built and convenient house, no material should be spared in places bearing the strain of the structure; do not save material in these places, as it will almost certainly be ruinous to the building in course of time; see that those rooms which are used mostly during the day-time be clustered together as much as possible; that there is not too much hall room; still, enough to insure a pleasing entrance to the house; the stairs should be comfortable and not cramped, all entrances well perfected, and the windows so disposed that they will admit sun and light in ample allowances, and, at the same time, be protected from the storms; that is, are on the opposite side from which the heavy storms are usually to be expected.

A goodly allowance of porches on the pleasant side and at all entrances will add greatly to the comfort of your home. Chimneys should be so placed as to ensure a good draft, no matter in which direction the wind may be. Concerning the exterior, the house should be in harmony with its surroundings; do not make the mistake of placing a low, flat-roofed building in a high country, or a sharp, steep-gabled structure on a flat plain.—*The Builder and Wood-worker.*

WHEN you have determined to build, the first thing to be done is to go to the best architect within your reach and consult him as to the most expeditious method of reaching the result desired. Do this before consulting any builder or contractor, and you will invariably find it to your advantage. The reason is plain. The architect stands as a disinterested third party between you and your mechanic, he having made a special study of the arrangement and convenience of modern structures, and being constantly employed in designing such, is better versed than any one else you could find. In selecting your plan, give the architect a short synopsis of what you consider best adapted to your wants, and the amount you desire to expend; then let him work the design up and submit it to you for inspection, which will enable you to see and correct all which does not suit you, and your house, when completed, will come up to your expectations.—*The Builder and Wood-worker.*

Consideration For Old Employes.

PHYSICAL vigor and mental activity are necessary in all kinds of employment and all sorts of business. Lacking either, the man is, in some degree, incompetent. The cases are exceptional where profitable employment is fitted to the infirm, whether physically weak or mentally slow. And yet there are cases where employment and occupation should be given to such persons, not alone as a matter of policy—to prevent mental and bodily injury—but as a duty. An employé who has spent the vigor of his best years in the service of an employer deserves something more in his last years than cold neglect. Even the turning out of an old horse to die is a subject for attention by the officers of humane societies.

If an employé is of any value whatever, he ought to earn for his employer something above his stipend; in fact, the labor of employés, combined with the judicious use of capital, should accumulate for the employer a competency, if not actual wealth. The wealth thus gathered represents in part, the excess of the value of the labor performed above the amount that has been paid to the laborers. Although the employé has no legal right to demand more than the agreed sum as wages, or salary, which he receives, the fact remains that the wages, or salary, may not represent the proceeds of his work in full.

This fact may not constitute even a moral claim by the employé for anything beyond his regular compensation, under any circumstances. It may be that the compensation was sufficient to have placed the employé, in his old age of feebleness, in a condition of comparative independence, but he may have neglected to provide for the inevitable rainy day. Employers have no special superogatory duties towards employés of this class. Nor is it, perhaps, incumbent on them to pension off old employés, as governments sometimes do public servants. The circumstances will alter the cases. It is not to be expected that employing establishments or individuals are to become insurers against the decrepitude of old age and its attendant incompetency. But the dictates of humanity and the demands of business policy may so far go harmoniously together as to prevent the too common spectacle of an old, faithful employé deprived not only of a position of profit because of inability, but of occupation adapted to his failing powers. There are few sadder sights than this, and pity for the unfortunate man and detestation for his though less or perhaps avaricious employer is felt by every spectator.

As men grow old in any particular service their business ways and work habits become fixed, and all the surroundings of their secular days' employments become more familiar to them than their home life. It is like casting them adrift without rudder, oars, or chart to turn out old employés under such circumstances. Who has not felt a pity for some superannuated employé thus set adrift, as he has noticed him returning occasionally to his old haunts, and looking about wistfully on scenes of which he once formed a necessary part, but in which he is now only an incumbrance and a disturbing element. Too old to start anew in another line, and possessing none of the hopefulness of youth and the ambition of mid-age, he becomes disheartened, melancholy, and perhaps imbecile, until death steps in to his relief.

There is a large manufactory in a New England State that for more than thirty years has been running with pecuniary success, employing young and old, male and female, in its various departments. When business has been dull, and the markets unstable, work has been reduced, and wages shortened, as was necessary to prevent financial disaster. But good employés were kept, if possible, even in the dullest times. There never was a strike, nor a threat of one, in this establishment. Among other humane practices and considerate measures for the comfort and well-being of their employés, this company keeps their hands even when old and unprofitable. There is one old man, now more than eighty, who has worked faithfully, for the best part of his vigorous manhood, for the company. He still works—not, however, full hours—and his employment is of so trifling a character that but for the circumstances it would be ludicrous. But the old man is proud of his employers and that he is still able to work, and is living a happy, contented life, believing that he is independent of charity and that he is still useful, if not necessary, to his employers. This is an example that might properly be followed by others.—*Scientific American.*

Genesis of a New World.

ON a beautiful summer's night, August 22, 1794, Jerome and Lefrancais de Lelande noticed a star in Aquarius, which they estimated of the seven and one-half magnitude. Six years later they thought it of the eighth magnitude. In appearance it resembles a star which is not exactly in the focus of the telescope. Herschel had observed it in September, 1782, and recorded it as an admirable planetary nebula, very brilliant, small, and elliptical. Lord Rose and Lassell perceived that it was surrounded by a ring, which gives it somewhat the appearance of Saturn.

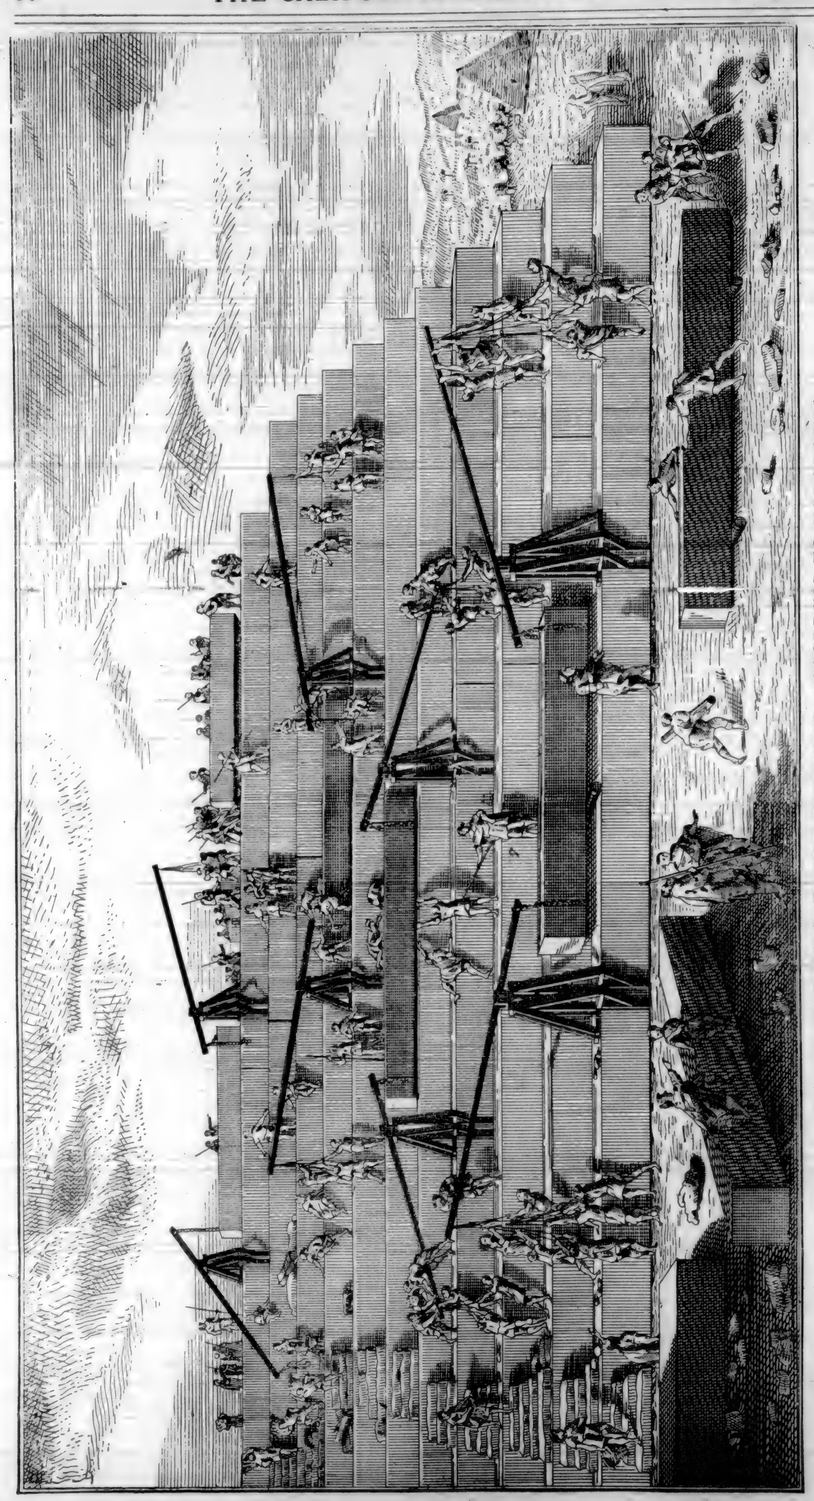

PLATE 6—BUILDING OF THE PYRAMIDS, ACCORDING TO HERODOTUS.

The Pyramids.

THE topic of the pyramids can never cease to be interesting to the intelligent and inquisitive mind. *When* were they built? *Who* built them? *How* were they built? *Why* were they built?—are queries to-day as they have been since authentic history began. Twenty-three centuries ago, the Greek Herodotus—father of history—stood before the great pyramid studying the same puzzles. He got no very clear answer to his questioning. The thousand scholars that since his day have struggled with the same problems have satisfied only, or chiefly, themselves. They have received no answer that the world accepts as final. The great pyramid at Ghizeh seems to antedate all others, and if its riddle could be solved, the mystery would be cleared. But when the architect of that monument closed its chambers to the world he buried the key in its dark bosom. The secret has been well kept. Like the inscrutable Sphinx—its companion in the grand solitude, whose lips are sealed—the great stone is silent. They have stood there and seen all History file by and said nothing. When the First Emperor drew up his French legions in the valley of the Nile, and pointing to the solemn structure by the desert, said, "forty centuries look down upon you from that pile" he spoke but the simple fact; for, indeed, like the everlasting hills it has stood there for ages. In truth we can hardly say when it was not there. The testimony of almost all authors shows that it was there nearly or quite 4,000 years ago. There are no monuments in Egypt older than this one. Some old writer speaks of it as the "terrible crystal of a former unknown time." Its age goes back, then, beyond Moses—beyond Abraham—beyond even the birth of the Hebrew or the Sanscrit languages. It is so old, indeed, that no contemporary writing relating to it exists. No book treats of it within 1,500 years of its foundation. There is, therefore, no clear history of it in existence. Almost its only record is itself. The story

of its real purpose is lost. We stand and gaze upon it and wonder what people lived there before its day long enough to develop a civilization that could produce such a structure as the great Ghizeh pyramid. Where did they originate? In whose brain grew that design? Who was the architect? We can only wonder. It seems to have been the first specimen of stone architecture known in the world—and Piazzi Smyth thinks "it came at once as a perfect specimen—an astounding, and, humanly speaking, an unexplainable mystery." If it was a gradual development, what centuries of slow growth lay between the first rude hut and such a building! He says again: "The grandeur and stability, as well as the minute perfection of its parts, are a marvel." Ferguson says: "It is the most perfect and gigantic specimen of masonry the world has yet seen." He says this with full knowledge of what Greece and her colonies, Rome and her colonies, have done in this line since this was built.

Greece was not born when this giant was being fashioned; and when we think of the long line of her famous sculptors and geniuses in the mechanic arts—of the Parthenon—and her temples on a hundred hills—we are dumb with wonder. Smyth, and Taylor before him, were so at a loss to conceive how such a structure could be produced with no previous model, that they concluded that the design was supernatural—God-given directly, and to an architect who was not an Egyptian. Smyth says "the original plans were based upon a knowledge of astronomy, geography and physics, so vastly beyond the unaided powers of man in that day that there is scientifically no resource for us but to allow that the designer *must* have been assisted by divine inspiration."

Prof. H. L. Smith, of Geneva, N. Y., speaking of the measurements of the queen's chamber in this pyramid, says: "Either there is proof here of a supernatural inspiration in the architect, or he possessed, in an age of absolute scientific ignorance, a knowledge of science equal to the most advanced of modern times."

It has always been a wonder how the Egyptians raised the great stones with which they built their temples and the pyramids. In many cases these were thirty to forty feet long, and three to four feet on the end. There has been much speculation in regard to their methods, but it is safe to say we do not know. Diodorus, a Greek writer, living about 100 B. C., says they used terraces upon inclined planes. Pliny, a Roman, 60 A. D., makes a similar statement, simply repeating it. Herodotus, a Greek, 484 B. C., says they used levers. He had visited Egypt, and got his information from the Egyptian priests, who ought to have known something about it. We will accept his story until we know better. He gives this simple description: "The stones were laid in courses, regularly diminishing in size. Each course was so much within that just below it that each front of the pyramid formed a stair. These courses can still be counted. Such being the case, it is easy to see that only time and patience were needed to raise the largest stones to any height. A very simple machine, very easy to manage (see p. 96), was placed upon the first course, by means of which the stones were lifted upon that for the second course, and when that was done, by a similar machine, stones were raised upon it to form a third, and so on to the top. "The plate shows that this machine was a simple lever, upon a pivot, turning in any direction, and worked by a great number of men." He says also that "100,000 men were employed on the great pyramid 20 years. They were ten years in getting the stones ready. Every three months they were relieved by an equal number."

The great pyramid at Ghizeh is the one to which attention has been most directed. Mr. Smyth says, "There seems to be a series of features in this pyramid which have no counterpart in any other." Without adopting the theories of Taylor or Smyth in all their fanciful details, we must admit that these indicate something more than a mere tomb in this wonderful structure. Let us notice *some* of these remarkable features.

First—the base is a perfect square; *Second*—the four sides incline toward the central vertical axis at equal angles. The angle is 51° 51′ 14″, and this is significant for it has been found that using this angle, and finding the vertical height of the pyramid by it, we obtain a very remarkable relation of lines. The height is not now what it was originally; for the top has been destroyed—cut down.

The theoretical height was found by triangulation to be 486+ British feet. One side of the square base was found to be 763+ British feet. Now the ratio of this height to twice the length of one side of this base was found to be exactly the ratio of that of the diameter of a circle to the circumference, viz., 1 to 3. 14159—a quantity much used in modern mathematics and of inestimable value. But there is no testimony in all history, no tradition or any other form of record whatever to show that this ratio was known to the human intellect for ages after this pyramid was built. How then came it to be expressed in this structure? Smyth claims that it completely solves the standing puzzle of the ages, viz., the squaring of the circle, for the height of this pyramid may be made the radius of a circle, whose circumference is exactly equal to the sum of the four sides of the square base. No other pyramid has this feature. How did the architect happen to hit it so exactly? Was it an accident or was it by design? If an accident, it is the most marvelous accident in history. If by design, how did the builder know the mathematical truth thousands of years before it became known to any other human mind?

Another wonderful accident is the angle of inclination of the passage into the pyramid on the north side. Setting aside all theories again, the measurements are there and may be accepted as mainly correct. Taking these as they are, and skillfully manipulating them, legitimately, as one may do the number 9 of the Arabic numerals, and many singular results follow as with that magical number. Did the builder play at puzzles as he built? For example, if certain measurements in the King's Chamber be taken and certain operations upon them be performed, the number 365¼ is obtained, the exact number of solar days in the year. This result has been reached in several independent ways.

Again taking certain other measurements, and performing similar operations upon them, the angle 23° 51′ 50″ is obtained. But this angle *happens* to be exactly the angle of the obliquity of the ecliptic for the year 2170 B. C., which is the date of the building of the pyramids, as believed.

But a resulting number of far greater importance than either of these has been disclosed. The cycle of the precession of the equinoxes has been computed by modern astronomers to be 25,827 years. Now exactly that number has been found in numerous instances by operations, like the above, upon the architectural lines of the great pyramid. Yet no such astronomical truth as this was known among men, historically, for nearly 2,000 years after the pyramid was built. How happens this number, then, to be builded into the whole structure as it seems to be? Is it an accident?

An English engineer had seen that the square base of the pyramid might typify a circle of which the vertical height of the pyramid was the radius, because there was found to exist that remarkable relation between the vertical height and twice one side of the base. Then he said, this circle *may* symbolize the earth's orbit, and the year may be evolved from it. And this height may also represent the radius of the earth's orbit, which will be the distance of the sun from us. So he took this vertical height in pyramid inches, changed them to British inches, then miles, and worked out the problem, and the result was 92,500,000 miles, nearly—a number almost identical with our very latest computations upon the transit of Venus, with all our refined methods.

Another striking feature, one of the curious problems of the great pyramid, is the fact of what is called its orientation—that is, its base being so fixed that its four sides face the four cardinal points exactly—due north and south, due east and west. Now, to place a structure built of layers of stone as large as those in this pyramid, and covering, as Proctor says, thirteen acres of ground, so as to be exactly in line with the cardinal points, is a work of no small difficulty to-day, even. Proctor says: "The only way it *could* be done was to cut a slant passage through the solid bed rock, directed to the pole star of that day, when crossing the meridian below the pole." This passage is toward the north. Toward the south, within the pyramid, how could a passage be cut on a true north and south line with no star to guide them? A beam of light from the north star down that north passage was re-

flected from a surface of water at the same angle as the entrance beam, and was their guide in cutting that passage. And all this was so exact that to-day astronomers can detect no error greater than about five minutes of space. This gives us some idea of the genius that directed the building of that structure.

Another interesting fact is, that this pyramid is placed almost exactly upon the parallel of 30° of N. Latitude, wha ever significance this fact may have. Then a vertical plane north and south through the pyramid marks the zero meridian for Egypt; and that entrance passage to the pyramid is in the plane of this meridian. Some other curious facts are these: This entrance passage has an angle of altitude of 26° 18′ about; and its direction is not to the exact pole of the heavens, but to a point 3° 42′ below that pole. Now it has been ascertained astronomically, that about 2170 B. C. the star called Alpha Draconis—or the brightest star in the Dragon—was just 30° 42′ below the pole, and its light would therefore shine down that passage, so that it was their north star. Showing that our north star was not their north star. At the same time Alcyone, brightest of the Pleiades, or seven stars, was on the meridian south, in the vertical plane of direction of Grand Gallery of the pyramid. At the same time also the celestial meridian of the Vernal Equinox coincided with this same Alcyone. It is supposed by those who think this pyramid is an astronomical building, that the Egyptian year began at the time thus indicated, viz., in the autumn, when the Pleiades crossed the meridian. Judge Haliburton of Halifax, by a remarkably patient research, has shown that many primative nations and also uncivilized tribes have always begun their year at this time. But a profounder problem than the beginning of an Egyptian year lies in the fact that this remarkable conjunction of stars shows also that it was the beginning of a cycle of the precession of the equinoxes, a period as before said of over 25,000 years. If, as Smyth says, this problem is recorded in the architecture of this pyramid—it is an astounding fact. Such are some if the wonders of the measurements of the great pyramid. If the conclusions are correct, they are verily wonderful. It is wonderful that any one at that age of the world, beyond the period of written history, could know the true relation of the circumference of a circle to its diameter—carried to five places of decimals; could know the shape of the earth, the length of its axis of rotation—therefore its size; and could derive a unit of linear measure from it as a standard; could know the diameter of the earth's orbit—therefore its circumference—deriving thence the sun's distance—length of a solar year and day; could so place the building that a vertical plane in it should give the true meridian for Egypt; that the opening of the entrance passage should admit the light of a star in the true north, and at the same time another passage admit the light of a star in the meridian in the south. More wonderful still, that they should know that cycle of the precession of the Equinoxes. If they did not know these things, how does it happen that the geometry of that structure gives the information? is it all assumption? has it been tortured out of the lines with no basis of fact?

Different mathematicians, by simply taking the measurements of the lines put there by the architect and solving the problems suggested by them, have made the astonishing revelations. If the results can be shown to be true, and the designer did not know the hidden secret in those lines—did not have any knowledge of the astronomical truths involved—can we help concluding, also, that he was guided and controlled by divine inspiration?

A Remarkable Work.

THE opening of the Darien Ship Canal redirects attention to one of the richest portions of the globe, which has been unnoticed for the greater part of the century. To understand its capacities we must go back to the records of the first discoveries and conquest of the Isthmus, when it paid tribute to Spain in thousands of gold and silver, and baskets of the finest pearls. Its great cities held palaces whose walls were a mile square, and fortresses which surpassed those of Europe. The ceiba tree and the tropic creepers have hidden the site of these grand ruins, but, guided by the light of history, the daring explorer will yet find not only these, but the deserted mines of gold and beds of sacred turquoise and of pearls. The history of Mexico and the Isthmus, in their early days, is one of the most fascinating pages in the world, whether to scholars or men of business, and it is fortunate that the period of reviving interest in these centuries, also, sees the announcement of the remarkable literary work which includes their history. The wealth of preparation lavished by Mr. Huburt H. Bancroft on his great "History of the Pacific States" affords a satisfaction to the world of which the volumes so far issued are a rich and surprising foretaste. The story of the conquest of a new world must have an absorbing interest, but the splendor of the natural resources of the countries reads like the tales of Eastern romance. From the treasures of material at command in his matchless library of 35,000 volumes on Pacific history, for which he has ransacked American and continental collections and Government archives, Mr. Bancroft has drawn a story of plain, authentic fact, which wears the coloring of romance. Old manuscripts, unknown to recent historians, and archives, supposed lost but brought to light by intelligent research, have added of late the missing links in the wonderful history of the discovery of America. The archives of Central American Governments, rare Spanish works, and manuscripts from the collections made by the Emperor Maximilian, and the eminent Mexican, Ramirez, have been sources of fresh and extremely interesting material, to fitly condense and convey which has been the labor to which Mr. Bancroft has devoted his best energies for twenty years, with the asistance of from twelve to twenty educated secretaries in translation and reference work. The history thus produced by an author of uncommon ability must take place as a standard authority on Western America, giving not only its past, but its natural history, in accounts of the scenery, productions and inhabitants of the countries from the Rocky Mountains to the Pacific, from Darien and Sonora to New Mexico, Arizona, California, Oregon and their sister States The information of all the writers that have ever written about these countries will be contained in Mr. Bancroft's Pacific History, a work so interesting that we expect to see it in every town and school library, if not in every household—the delight of the school-boy, for its marvelous stories of adventure; of the politician and the literary man alike, for its clear precision and its rich grasp of fact. In Europe an order of nobility would be the honor assigned a labor of such value—but the author's best reward will be to see his work read and beloved by the people for whom he wrote. The praise of the great scholars of Europe and America, of Carlyle, Herbert Spencer, Whittier, Longfellow and Draper, has been warmly given to his work, which, however, was written with the purpose to bring the information of a princely library within the reach of American homes. The large, open print, firm paper and binding have been selected to make a book welcome to the eye and lasting for use; one which will take the first rank among standard histories, and equally so in the interest of general readers.

Information in regard to the prices, etc., of this remarkable series, can be obtained by addressing Bancroft & Co., San Francisco. Inquiries addressed to this office will also receive prompt attention. Eleven volumes are now ready, and it is the intention to have a volume ready every fourth month until the series is completed.

LOW BEDS.—The use of the low bedsteads, with the trundle-bed, ignore a great and important principle, that relating to the fact that near and on the floor will be found the most poisonous gases, the carbonic acid of the sleeping room, since this is heavier than the air, falling and flowing into the lower parts of the house like water. It is cruel enough to put the children in a room which is already occupied by a sufficient number of persons—two are enough—without putting them, at the time when they are growing, and need every possible favorable condition, where they continually breath the worst air—all of it being filthy enough—malaria!

Lumber Receipts.

THE following statement in regard to lumber receipts for the first six months of this and the preceding year may be of interest to many as showing the forward state of the building interests at the present time:—

1882.		1883.	
Lumber, ft.	69,869,381.	Lumber, ft.	76,280,301.
Shingles, No.	13,322,761.	Shingles, No.	13,610,000.
Laths, No.	6,588,100.	Laths, No.	8,289,520.

The Material and Manufacture of Canes.

THE manufacture of walking-sticks and umbrella handles is an industry in which a great deal of capital is invested. The material is as various as can well nigh be conceived of. The Chicago *Times* recently had an article on the subject, from which we extract:—

Many are of imported woods, some from the tropics, China, and the East Indies. The celebrated Whongee canes are from China, where they are well known and celebrated for the regularity of their joints. which are the points from which the leaves are given off, and the stems of a species of phyllosiachys, a gigantic grass, closely allied to the bamboo. The orange and lemon are highly prized and are imported chiefly from the West Indies, and perfect specimens command enormous prices. The orange stick is known by its beautiful green bark, with fine white longitudinal markings, and the lemon by the symmetry of its proportions and both prominence and regularity of its knots.

Myrtle sticks possess also a value, since their appearance is so peculiar that their owner would seldom fail to recognize them. They are imported from Algeria. The rajah stick is an importation. It is the stem of a palm, and a species of calamus. It is grown in Borneo, and takes its name from the fact that the rajah will not allow any to go out of the country unless a heavy duty is paid. These canes, known as palm canes, are distinguished by an angular and more or less flat appearance. Their color is brownish, spotted, and they are quite straight, with neither knob nor curl. They are the petioles of leaf stalks of the date palm. Perhaps the most celebrated of the foreign canes are the Malacca, being the stems of the Calamus sceptonum, a slender climbing palm, and not growing obout Malacca, as the name would seem to indicate, but imported from Stak, on the opposite coast of Sumatra. Other foreign canes are of ebony, rosewood, partridge or hairwood, and cactus, which, when the pith is cut out, present a most novel appearance, hollow, and full of holes.

The manufacture of canes is by no means the simple process of cutting the sticks in the woods, peeling off the bark, whittling down the knots, sand-papering the rough surface and adding a touch of varnish, a curiously carved handle or head, and tipping the end with a ferrule. In the sandflats of New Jersey whole families support themselves by gathering nanneberry sticks, which they gather in the swamps straighten with an old vise, steam over an old kettle, and perhaps scrape down or whittle into size. These are packed in large bundles to New York City and sold to the cane factories. Many imported sticks, however, have to go through a process of straightening by mechanical means, which are a mystery to the uninitiated. They are buried in hot sand until they become pliable. In front of the heap of hot sand in which the sticks are plunged is a stout board from five to six feet long, fixed at an angle inclined to the workman, and having two or more notches cut in the edge. When the stick has become perfectly pliable, the workman places it on one of the notches, and, bending it in the opposite direction to which it is naturally bent, straightens it.

Thus sticks apparently crooked, bent, warped, and worthless are by this simple process straightened, but the most curious part of the work is observed in the formation of the crook or curl for the handles which are not naturally supplied with a hook or knob. The workman places one end of the cane firmly in the vise, and pours a continuous stream of fire from a gas pipe on the part which is to be bent. When sufficient heat has been applied, the cane is pulled slowly and gradually round until the hook is completely formed, and then secured with a string. An additional application of heat serves to bake and permanently fix the curl. The under part of the handle is frequently charred by the action of the gas, and this is rubbed down with sandpaper until the requisite degree of smoothness is attained. —*Scientific American.*

Why Some Mechanics Don't Get On.

WE were much interested the other day in drawing from one of the oldest practical mechanics of Cleveland the secret of his success.

Said he: "I have always made it a rule to do my work so well that it left a good impression on my employer." There is more in this than at first appears. Hard work is one thing; conscientious work is another. The hard worker may outwardly conform to all the requirements of the shop; he may always be in his place at the starting of the machinery; he may take short noonings, and he may be among the last to drop his tools at night, but after all he may utterly fail to get on in the world, and why? Let our experienced informant answer: "I know of a young man of just that kind. He works hard enough and wants to succeed, but somehow he can't. He came to me for counsel, and I found that he was slighting his work. That is, in his anxiety to turn off a large amount, he neglected the finish which always tells on good work. The consequence will be that, unless he makes a change, when times are dull he will be one of the first to be dropped by his employer." Superintendents and foremen notice these defects more closely than many are aware. The man who slides over his task, who lacks in thoroughness, who lets an unfinished piece of work leave his hands, is marked. In the unwritten law of the shop he is barred from promotion, while the conscientious workman is morally certain of advancement. Is the tendency of the day in the direction of a better finish to work? We think it is. As machinery is brought into competition the strife will be to secure superiority in cheapness, simplicity, and finish. Here it is that the thorough workman brings into play all the resources of his skill and honesty—his "mechanical moral sense," it has aptly been called. Here it is, too, that the slovenly, or careless, or hasty workman utterly fails. There are some forms of bad work that can be deftly covered up, but the compensations of life bring the inevitable result—failure to him who does not put his heart in the work, success to him who not only does his task, but does it well.—*Trade Review.*

Whitewashes.

THERE are several methods of making serviceable wash. One is made as follows: Three pecks of water lime, one peck of silver sand, and half a peck of salt. This is used for old, rough fences and outbuildings. The common whitewash is made by putting quicklime into a tight barrel, pouring on water to slack it, and adding water till it is of the consistency of cream. This is used for ordinary work. But a much better whitewash, which stands weather well, is made as follows:—

Put half a bushel of quicklime in a barrel and add boiling water until it is covered nearly six inches deep; cover the barrel to keep the steam in, and when the violent ebullition is over, add water enough to bring it to the consistency of cream, allowing four pounds of rice flour to each half bushel of lime, or the rice flour may be mixed with the water for slacking, mixing the flour carefully in cold water, before putting it in the hot water. Stir constantly in the hot water until thoroughly set, and then pour it all over the lime, as directed.

To improve the above, add two pounds of sulphate of zinc and one pound of salt. To change the color, add yellow ochre for cream tints, raw umber and lampblack for gray tints, and umber, red, and lampblack for fawn tints. The permanence of whitewash thus prepared is remarkable, and, when once tried, will be used to the exclusion of the ordinary mixture. —*The Pacific States Watchman.*

M. FAVOL, a French investigator, has found that the creosote treatment for the preservation of wood sometimes doubles the durability of oak timbers used in collieries, but has little influence on pine. He further says that oak prepared with ferrous sulphate lasts ten times as long as in its natural state. It should be immersed twenty-four hours in a solution of 200 grammes of ferrous sulphate.

THE cable system for street-car traffic seems to be making some headway in England and Scotland. At a Council meeting in Edinburgh, lately, permission was given to lay down a length for trial, the Council reserving the right to reject it, if deemed desirable, after an inspection of the Highgate, London, cable railway system in June next.

ACORNS from America are in demand in Europe, for the propagation of oak forests. A special agent for the forestry department recently shipped 300 bushels of red-oak acorns and 120 bushels of pignuts to England and Germany, where they are to be planted next spring.

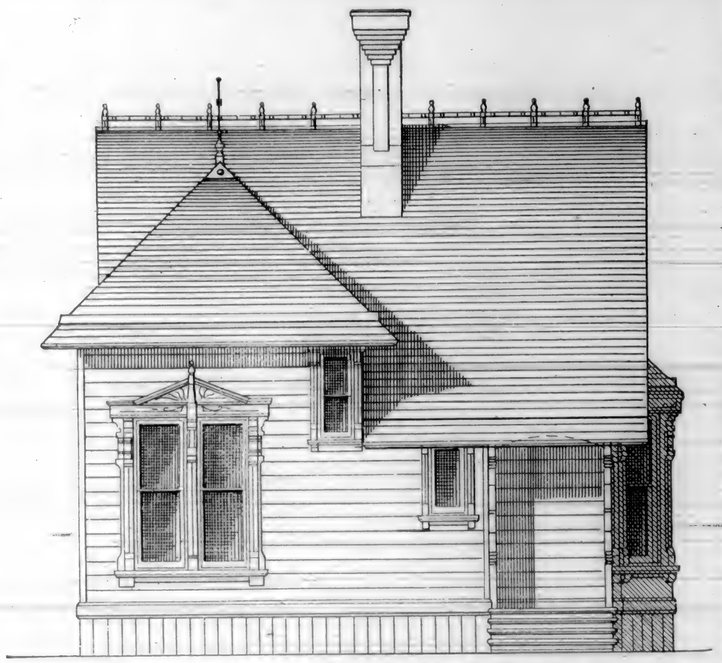

PLATE 6—A COUNTRY COTTAGE. FRONT VIEW.

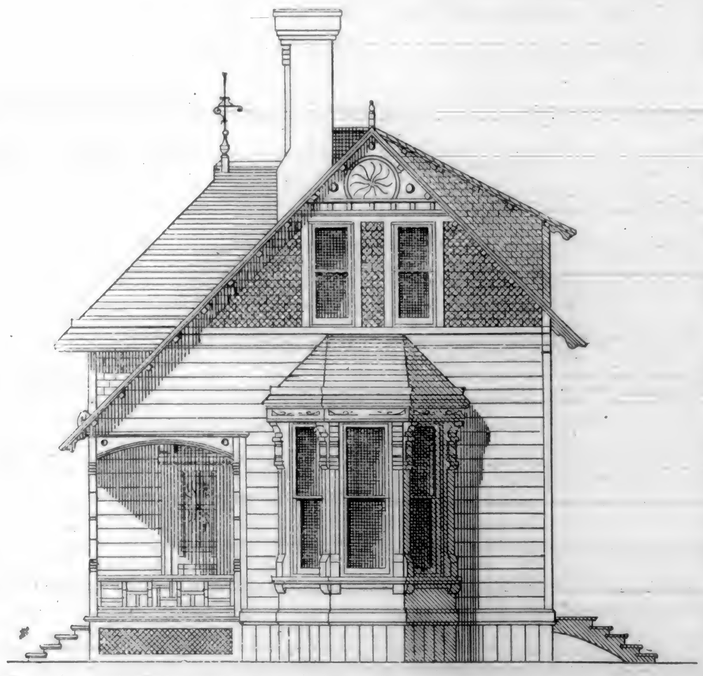

PLATE 7—A COUNTRY COTTAGE. SIDE VIEW.

Arbor Day.

THE people of this State should rise up and demand that one more holiday be added to the too few which we celebrate. And no more appropriate day could be named than to follow in the footsteps of some of the Eastern States, and name a day on which all could join together and have a merry time planting trees. We hope our next Legislature will take this matter in hand and establish a grand State holiday to be known as Arbor Day; and let old vie with the young in transforming our valleys into magnificent wooded districts. Should our wise Solons establish such a holiday, it is to be hoped that they will provide for the proper maintenance of the trees after they have been planted. This might be accomplished by offering premiums for a certain number of trees that present a healthy appearance after a certain period of growth. We sincerely hope that the journals on this coast will discuss this matter in full before our next Legislature meets.

Draughts or Slow Poison.

AFTER all that has been said and done about the so-called "ventilation" of our public rooms, the people who frequent them are still shut in, in nine and a half cases out of ten, to a choice between taking poison and getting a chill—with the facilities much greater for the former. The average assembly room is still typified by the "hot air receiver" in which Adirondack Murray was once lecturing. It was built in the regulation fashion, with close walls on two sides, pierced in four places with small openings into dead-air flues, called, by a fiction of the architect, "ventilators" but up or down which no current was ever known to pass. The ceiling was, of course, solid, and the only chance to let in fresh air to the thousand people who were trying to keep up their heart and brain action on an atmosphere composed of lung exhalations, burnt-up air, and unconsumed gas, was to let down the large windows in the end. Up and down went the rattling sash and rustling curtains, as the gaspers and freezers took turns at the windows. Finally, the lecturer stopped and said, with the coolness and humor that characterized him: "Friends you may fix the windows anyway to suit yourselves; only if I am to finish my lecture, I should like to have them stay fixed, one way or the other. For myself, if I am to have a choice between freezing to death or suffocating, I should prefer the former method as being cleaner. But, if the world stands for another year, and this dreadful hall with it, and you are to have another course of lectures, I would advise you to punch a hole through that roof," indicating the highly frescoed ceiling with his superb gesture.

The process hinted at in this rough suggestion has been followed in many of our pretentious halls and theaters. The builders have "punched a hole through the roof," in a more or less ingenious and artistic fashion; but, in thus providing an escape for the bad air, they have exposed a large percentage of the occupants of the room to direct or cross-currents of air every time a lobby door is opened or a window is raised. There is yet no science of ventilation; or, if there be, it has not been applied where it is most needed. Many fairly effective devices for taking the overheated air out of a room have been invented; but the rooms are rare into which any adequate supply of pure air is introduced. The furnace fiend in the cellar will belch his blighting breath into a room as fast as it can find a way out—and too often faster, as the baked brains and laboring lungs can testify. But a rational system of ventilation, based upon the law of demand and supply, and avoiding stagnation on one hand and draughts upon the other, has not yet been brought within the reach of the general public. People susceptible to the insidious effect of foul air, and who visit places of public amusement, know what a "theater headache" is. They have a reminiscence of the taste of the atmosphere in their mouth the next morning, though they may not know what it is. Of all places in the world, except sleeping or thinking rooms, where pure air is needed, a public dining-room is the oftenest neglected in this particular. Added to the heat of the furnace or the steam-pipes, is the smoke of the gas and the scent of the dishes, and sometimes the fumes of the kitchen. In our grand hotels, elegant and perfect in all their other appointments, there is often—we may say commonly—no way of reducing the temperature and freshening the air except by lowering a window—with what effect Mr. Fitz feelingly hinted in the humorous speech to which we alluded in the opening. It destroys half the enjoyment of a good dinner to introduce pure air in this fashion, merely as an *entre* in the elaborate *menu*. One does not want to carry away incipient pneumonia or an aggravated catarrh as the penalty for dining away from home.—*Ex.*

PRACTICAL CARPENTRY.

PRICE $1.00.

A guide to the correct working and laying out of all kinds of Carpenters and Joiners' work. Solutions of the various problems in Hip roofs, Gothic work, Centering, Splayed work, Joints, Hinging, Dovetailing, Mitering, Timber Splicing, Hoppers, Skylights, Raking mouldings, etc. This work should be in the hands of every mechanic. One of the features to which this book will undoubtedly owe its success, is the absence of those numerous formulas which serve only to confuse the ideas of so many workmen. Everything is written in a clear, concise, and practical manner, and its utility is brought within the grasp of those workmen who have not had the benefit of a school education. We will send the above work to any address upon receipt of $1.00.

IF the manufacture of glass is being tempered according to the building developments of the country, then the sash, door, and blind manufacturers can be said to have before them a prosperous demand. It is stated there are fifty new glass factories being built in the different States. To quite an extent glass means sash, and sash means doors and blinds.

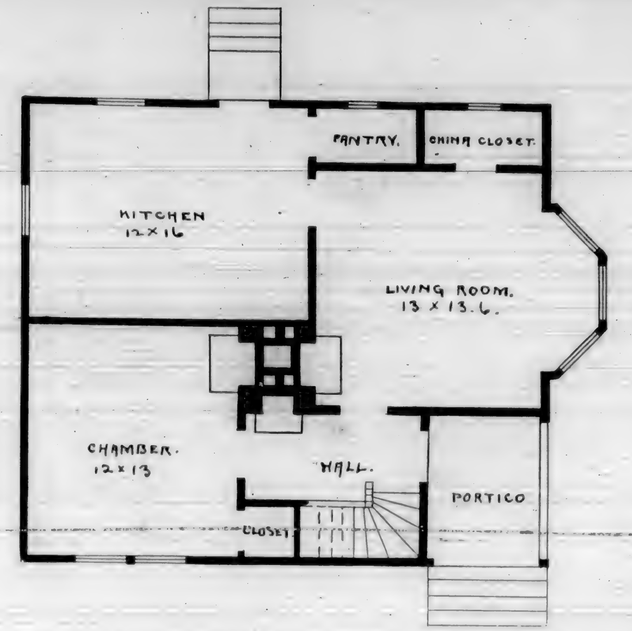

PLATE 8—A COUNTRY COTTAGE. FIRST FLOOR PLAN.

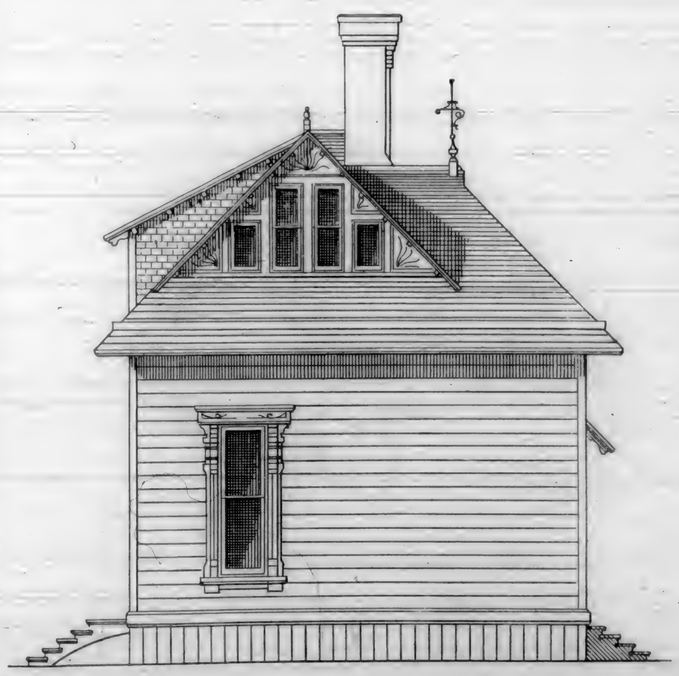

PLATE 9—A COUNTRY COTTAGE. SIDE VIEW.

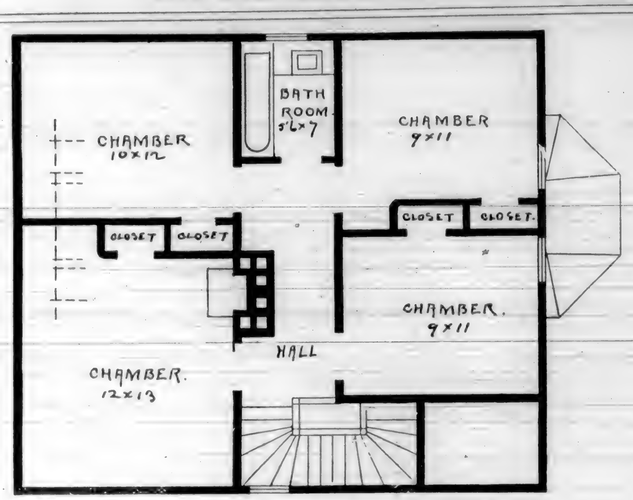

PLATE 10—A COUNTRY COTTAGE. SECOND FLOOR PLAN.

A Practical Answer to the Dr. Ayers' Theory.

THE following letter from one who is a prominent business gentleman, residing in one of the choicest elevated sections in the city, in a ten thousand dollar residence, is a conclusive contradiction of the fallacy recently promulgated before the Medical Society of California:—

"JUNE 3, 1883.

"MR. WOLFE: We are all down with malarial fever, and I am satisfied that the sewerage and plumbing of my house has much to do with it. Yesterday I noticed a terrible smell in the basement, coming from where the wastes connect with the sewer and hopper. The basement was closed, and, no water being run through the pipes during the day, the smell was intense, and as soon as I let the the water on, the smell went away. Whether the sewer is broken, or the joints in the sewers or plumbing pipes bad, I do not know, but we smell the sewer gas through the house and are all sick. I want you to examine where the fault lies, and have it remedied. My wife threatens to leave the house. The plumber has not done his work right, and we are alarmed for fear of the consequences. See whether the sewer trap is all right, and have large vent pipes put in, and make them run up above the shingles. I am afraid that the trap under the bath tub is not safe and it syphons out. I am greatly alarmed, for we have never had any such sickness before, and all the indications are that our present troubles come from the sewer gases. This is the opinion of our physician also. Please attend to the matter at once."

The foregoing is but one of hundreds of similar cases in San Francisco, and an exemplification of the folly of owners' purchasing houses built years ago, when sanitary science was in its infancy, and architects, owners and builders had not acquired the knowledge since obtained in reference to the importance of perfect sewer and plumbing work, nor learned to realize that the underground conduits with which all buildings are connected, contain terrible death-producing agencies. The residence in question was built some ten years ago, by one of the present popular architectural firms in San Francisco, who may have exercised the best judgment then enjoyed, but which now develops a degree of error illustrated by the foregoing. After the recent purchase by the present owner, he made, as he supposed, all necessary improvements to correct the existing evils, but failed in his attempt, and to obtain perfect immunity from the effects of sewer gases, will be required to expend considerable more money; but when that shall have been done, it will require time to remove the impressions produced by present family afflictions, and establish a feeling of confidence that loved ones are safely protected from the bad consequences which follow in all cases where sewer gases are allowed to work their way into dwellings. If sewer gases are not promotive of any "special type of disease," they are nevertheless a means by which thousands are daily prostrated on beds of sickness, and thousands consigned to that slumber from which nothing short of the Gabrielic trumpet will ever awaken.

PLEASE NOTICE.

The 75-cent edition of the Steel Square and its Uses is OUT OF PRINT. We cannot supply any more, as we have received notice from the publishers that their stock of that edition is completely exhausted. We have a number of the new and enlarged edition, which we will mail direct to any address upon receipt of

ONE DOLLAR.

This edition contains 30 more pages than the first one issued.

The Care of Fixtures.

THE most troublesome of all is the ordinary house sink, into which the bulk of the greasy water from dish-washing is emptied. Contained in the hot water, the grease is dumped into the sink and out at the drain. Being chilled, however, in its contact with the cold metal of the sink or drain, it is at once deposited about the strainer and proximate waste pipes, the greater portion being deposited on the inner surface of the traps, where it remains to decompose. Here something more than water is necessary, and when, as with the modern flat or tenement, the sink is made the receptacle of the suds on wash-days, the drain is kept moderately and sometimes perfectly clean by reason of the various washing-sodas now in use. Though the grease has been deposited by means of hot water, it is not safe to expect that hot water alone will remove it, since it was the chilling of the hot, greasy water that first deposited the refuse grease. There are special fixtures for catching this greasy deposit at various points along the drain, but the better way is to eradicate the objectionable and carry it off altogether.

Where the sink is used for kitchen purposes alone, and there are no weekly flushings from the wash-tub, it is necessary to take pains to remove the grease by special means, introducing into the dish-water some one of the sodas or ammonia. The tubs, whether in the laundry or bath-room, require moderate though timely attention. In the case of the laundry tubs, the deposit of soft mud, left from clothes washing, is partially deposited at the lowest portions of the tubs, or sticks to the corners or joints, and if, as is often the case with what are called stationary tubs, a quantity of water is left in and the lids shut down, decomposition soon sets in, and an odor far more offensive than the sewer gas is experienced on lifting the lid or stirring the water. The tubs have to be thoroughly washed and flushed before the odor is thoroughly removed.

The application of disinfectants is of no use; cleansing must be resorted to. So, too, with the bath-tub, a similar deposit is left from the water either at the bottom of the tub or in the drain, or more especially in the trap.

All this trouble from the tubs can be prevented by proper care and cleanliness after use. They should be thoroughly washed and flushed after each service.

With urinals another special method of cleanliness is necessary, for while there are no greasy deposits, such as already described, there is, owing to the very rapid decomposition that sets in, a special demand for immediate flushing after use, or they will shortly become most offensive. Constructed of a proper non-absorbent, non-porous and non-corrosive material, a liberal flushing immediately after use will be sufficient, unless contained in a close and warm room If the room is not properly ventilated, it is next to impossible, even with a most liberal flushing, to prevent an unpleasant as well as an unhealthy odor arising.

Exterior Painting.

THE BEST MATERIAL.

THE public are indebted to the architect and builder for accurate and becoming designs, and for good and careful construction of buildings, but not always for their methods in painting. Frequently their specifications for material and their methods of application are mistaken, and do not result in the best and most economical work. For instance a contract may require that the exterior of a house shall be painted in pure white lead and linseed oil. Undoubtedly pure white lead has superior covering properties, and with good linseed oil makes a handsome surface, but it is not by any means the most durable or cheapest coating available. A proportion of zinc white, depending upon the amount of coloring matter employed, mixed with the pure white lead, will make a much better paint. There are technical reasons upon which this assertion is based, and they will be appreciated by every one, though he may have no practical experience with paints. It will be readily seen that the adhesive properties of the paint consist in the vehicle with which it is mixed. If water were used the adhesion would continue only so long as the paint should retain its moisture and the dry powder would be easily rubbed off. The same result would follow if the pigment were mixed with oil, as soon as the vehicle were absorbed, disintegrated, or otherwise removed from the powdered lead. Now it is a fact that a paint consisting of pure lead and the best linseed oil will soon disintegrate, leaving the powdered lead free to be easily rubbed off. On the other hand, the oxide of zinc forms with oil a paint which when dry assumes the appearance of an impervious enamel. This comes from the nature of the pigment, by which a chemical combination is effected. The writer, therefore, after many tests, does not hesitate to recommend a mixture of zinc with lead for all exterior paints. We said the proportion of zinc should depend upon the colors with which the paint is to be mixed, for ochres, umbers, siennas, and Venetian red act in the same way as zinc, and are preventives of the chalking difficulty to which clear lead is subject. As to the proportion which is the most economical with the best results, the writer would recommend that for the upper coat, say of a three coat job, standard white lead will bear 25 to 35 per cent. of zinc. If any considerable proportion of the colors named were employed in the mixture the smaller percentage has, in the experience of the writer, worked best. Many painters use the zinc in the priming coat, but clear lead, from its great covering power, is regarded as preferable. The inexpert reader may ask, If zinc is so good why not use it clear? There are two technical objections. First—Zinc lacks body or covering properties, being much less opaque than lead. Second—Zinc clear makes a hard and brittle enamel, which is subject to what painters call cracking and chipping. No matter how employed as a paint, it must, for these reasons, be tempered. The prepared brands of zinc white are tempered in their manufacture to avoid these very objections.

Now as to errors in methods of applying paint. We once saw a contract for painting a railroad depot and passenger house, in which there were many elaborate and small architectural decorations, requiring to be picked in with several different colors. By the terms of the contract it was a three coat job, and it was required that the painter should "pick in" the colors in each coat. The colors were such that the picking in needed only to have been done on the last coat. As such painting requires great care and entails much labor, the consequence was that a large amount of labor was lost in the unnecessary work of two "pickings in." Besides, in spite of the care of the painter, the painting was rough and slovenly, much aggravated by the repeated work of matching lines and colors. We recollect also that the painter was greatly out of patience because the contractor would not listen to his suggestion that he could do the painting much better with a single coat of the "picked in" colors. Many architects are expert in the selection and arrangement of colors and tints on an exterior, but it ought not to be expected that they can have the practical knowledge of paints and material, and the best methods of application, which are requisite to avoid mistakes such as those above alluded to.—*N. C. Weiss, in Building.*

Strengthening a Foundation.

AN interesting way of strengthening a weak foundation was recently tried on a new building that suddenly commenced to settle. The excavation for the walls had been carried down until a mixture of coarse sand and gravel was found, which was deemed suitable. During a heavy rain water found entrance to the cellar, when the sinking resulted. The building was braced, the cellar drained, and then the inside wall of the foundation was uncovered down to a little below the bottom. A A-shaped piece of masonry having a height of about twice the width of the base was then built, the bond between it and the wall being carefully looked to.

After this had been finished upon the inside, it was repeated upon the outside. The base of each of these pieces was equal in width to that of the wall, so that the operation practically trebled the bearing surface of the foundation. It may be well to add that the water will not again be permitted to enter that cellar, as every passage way has been securely closed.—*Scientific American.*

Prescott's Truss Hanger.

THESE Hangers are particularly adapted for use upon barn, stable, depot, and storehouse doors, or in any place where elegance of finish is not required. A child is able to move a door hung with this Hanger. Dunham, Carrigan & Co., Agents.

Building Intelligence.

OWING to the immense lot of extra work caused by a complete change of type in our last issue, a few typographical errors crept in our columns. The buildings on cor. of McAllister and Filmore reported to cost $2,100 should have been $21,000. The alterations cor. Jessie and 18th streets, reported as $1,000 should have been $10,000.

SAN FRANCISCO.

Channel, nr. Sixth. Two-story frame, and one-story brick.
O.—A. Waldstein.

The California Architect and Building News.

VOLUME IV. NUMBER 7. | SAN FRANCISCO, JULY, 1883. | $2.00 per Annum, in Advance. Single Copies, 20 Cents.

THE

California Architect

AND

BUILDING NEWS

Published on the 15th of each month

BY THE

San Francisco Architectural Publishing Co.

JAMES E. WOLFE, GEO. H. WOLFE,
EDITORS AND MANAGERS.

Rooms 11, 12, 13, No. 240 Montgomery Street.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, per square, each insertion	$ 2 50
Back " " " " "	2 00
Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each Subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is ¼ of an inch in length by width of the column. When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received Unless requested, we do not send receipts.

Bound Volumes of this Journal.

Bound volumes of 1879, 1880, 1881, and 1882 (in one book) complete, with all ads. and covers removed, will be sent to any address upon receipt of $8.00.

Bound volumes 1881 and 1882, each $2.50
" " 1880 (only a few left) $2 00

In 1880 the subscription price of this journal was only $1.50, and we have put the price of bound volumes accordingly.

Volumes of 1882 and those containing all the numbers from the first issue, bound in one volume, are supplied with a full index.

Any one failing to receive a complete index will be supplied by sending a postal card to this office with their address.

Market St. West of Sixth St.

THE day is not far distant when Market Street, west of Sixth Street, will become "all alive" with building improvements. The feeling hitherto has been that the time had not arrived for the erection of substantial brick edifices beyond Sixth Street—that trade had not made a channel in that direction, and that money expended in the erection of buildings would be unremunerative, until trade and traffic forced their way beyond present limits on the line of that great thoroughfare. This has been a mistake on the part of property owners, and the wonder is that men of business intelligence, owning "city hall lots" and others in the neighborhood, have not been able to discover their error. The same state of feeling existed a few years ago, in reference to the portion of the same street between Third and Fourth Streets. When Bancroft & Co. first contemplated removal to their present location, they hesitated, fearing that they would be placing themselves beyond the limits of trade. But the sequel demonstrates the fact that they acted wisely, for instead of getting beyond business circles, their trade and custom followed them, and the movement had the effect of inducing others to locate in the same block, and, in a very short space of time, the entire business character of the neighborhood was changed; and to-day it stands unexcelled by any other block in the city of San Francisco. While the owners of the property in question have thus acted, many of those owning property on less promising business streets, have exercised a greater degree of business tact, in making improvements and *drawing trade* in their directions. On the lines of many of the "side" and "off" streets, store improvements have been made, which have rented at greater or lesser rentals, and if some sacrifice had to be endured for a time, there has been a daily gain in business permanency, with continued increase in the value and prospects of such property; for trade once attracted to any neighborhood generally continues, so long as dealers offer inducements to customs. Numerous cases might be cited in illustration of this view of the case, and we have no hesitancy in saying that if the owners of lots beyond Sixth, extending to Ninth Street, had, years ago, improved their property with a fine class of buildings, they would now all be occupied; and instead of "sand lots" and vacant premises, more valuable to the city and county as a source of tax revenue for the time being, than to their owners, a successful line of stores might be now flourishing, with a flow of business prosperity along the whole line. To have done this five years ago, the usual sacrifice of interest on the investment might have been experienced for a time, but in return for such loss, the property in question would have gained the advantage of an established business footing; whereas, as the matter now stands, a large sum has been added to the first cost of the property, in the way of years of interest and taxes, which must ever hereafter be included in the total cost, up to the time of improvement. And as far as such sacrifice is concerned, it will have to be submitted to, whenever improvements are made, for it seldom happens that trade is transferred with a rush to any new locality. It always requires time, except in the old established business centers. In this view of the case, the sooner the owners of the property in question move in the matter, the better for their own interests. The new Odd Fellows Hall, Market and Seventh Streets, will contain stores on first floor, which are likely to be occupied by enterprising firms, who, as pioneers, will establish that point as the nucleus of business enterprise. And we are well satisfied that if there is a general move made in buildings on the City Hall lots, a large amount of trade will be drawn that way, and, inside of two or three years, the whole neighborhood be alive with trade activities. If nothing in the way of improvements is done until the positive demands of business open the way, there will be a long wait, and a large additional sum in taxes and interest be added to present—total cost of the property in question. Meanwhile, owners of property on the streets opening into Market Street—O'Farrell, Eddy, Ellis, Stockton, Powell, and Mason Streets north, Mission, Sixth, Fifth Streets south, Larkin and Ninth Streets west, will continue to provide store and other building facilities, virtually encircling the locality in question, and securing trade which would long since have been drawn to and centered in the locality under notice, had there been, or were there at the present time, rows of store on Market Street, between Sixth and Ninth Streets.

The street car facilities will not for many years be better than they are at present; and with the exception of a new cross line, running north through Jones Street, as has been talked of, there seems to be no necessity in any direction for additional lines. Market, Valencia, Haight, and Folsom Street lines passing directly through and along the blocks named, with Ninth and Larkin Street lines at the western boundary, McAllister Street line at the north, Mission Street line within one block, and the Sixth and Taylor Street line on the east, with complete transit facilities from

all parts of the lower section of the city, and from Oakland, Alameda, and by way of the numerous lines concentrating at the ferry slips—it appears to us that if the owners of the property in question would take a broader view of the possibilities surrounding their investments, they would forthwith proceed with the erection of first-class buildings, and enter into a vigorous competition for the trade advantages which are now distributing and establishing themselves in so many inferior localities.

No Decision Yet—Lien Law.

A DECISION by the Supreme Court, construing and defining the legal force and effect of the present Lien Law of this State, has been anxiously looked for by thousands of interested parties for six months or more. A degree of uncertainty surrounds all building interests, owing to the unsettled features of the law as it stands recorded upon the statute books. The new dress in which the law is clothed by the new Constitution, creates an uncertainty in the minds of the legal fraternity, and the opinions advanced by lawyers are entirely speculative. Some holding that the law as written is effective, while others maintain that no law which contravenes,—practically nullifies the agreements and obligations of contracts,—can be enforced. The issue involved in the case now before the supreme tribunal of the State, covers the whole ground, and the decision when rendered will be one of the most important that has been considered and decided since the adoption of the new organic laws of the State; as it will establish the responsibilities of owners of buildings and construction improvements generally, and lay the foundation upon which contracts, bonds, etc., must be constructed, and settle the vexed question whether owners can be held for deficiency amounts beyond the sum of contract. Hitherto the decisions upon the same issues under the old Constitution, have all held that the terms and agreements of contracts were conclusive, and that owners could not be held for any deficit that might occur from any cause. What the decision will be in the case now pending cannot be known until the decision now so anxiously waited for and desired is made known.

The Garland Trap.

MUCH has been said and written in regard to the efficacy of traps in preventing sewer gas from permeating our dwellings. But the climax of perfection was not reached until the time of the introduction of the Garland Trap. In fact his name is being used as a house word by many of our citizens; for after performing their necessary ablutions, they point under the washstand and say, "Old Garland is there," meaning that a perfect sewer gas protector by that name prevents the effluvium of the noxious gas from coming into the room. Safety and simplicity are the essential characteristics of the Garland Sewer Gas Trap.

THE *S F Chronicle* of July 1st, in its article, "City Laws," "some figures concerning building operations for the past six months," etc., says: "The *most reliable* source as to the number of buildings now going to completion, is, perhaps the books of the Spring Valley Water Works"—which for the past six months gives 391 as the total of buildings with which the pipes of the company have been connected. Then follows "Another authority [meaning the CALIFORNIA ARCHITECT AND BUILDING NEWS] which claims to have taken much pains in compiling valuable statistics, gives the following figures:" this is followed by our semi-annual statement, showing the number, as reported in this journal, to be 424, or 33 more than the number given in Spring Valley's statements. It then adds, to qualify the discrepancy in the two totals, that the reports of this journal "include of course, many which are not supplied with Spring Valley water."

We refer to the article mentioned, because it is incorrect in some respects, and not editorially clever in others. *First*, it is not true that the "Spring Valley Water Works' books are the most reliable source," and the *Chronicle* so admits when it says the reports in this journal "includes many which are not supplied with water," which is a fact. A considerable number of buildings are reported by us, into which Spring Valley water never enters, and the books of that company cannot therefore ever be a "reliable source" in reference to the number of buildings erected in this city. The water company's books however serve to sustain the practically, unimpeachibility of the reports of this journal, and it would have been no more nor less than fair and friendly, had the *Chronicle* acknowledged this fact, which must have been clearly evident to the writer of the article referred to.

Secondly, it was not kind nor generous on the part of our contemporary to say "Another authority which claims to have taken much pains" etc., when it would have been just as easy to have mentioned the name of this journal, as that of the Spring Valley Water Works, particularly as the figures given, and the admission made by the *Chronicle* show that our statements were more nearly correct than the "reliable source" credited.

Again, our contemporary has too often availed itself of the information contained in our monthly reports of building intelligence to render the language—"another authority which *claims*" etc.—justifiable. We *claim* nothing that is not ours by right of actual fact, and as far as our reports of building operations are concerned they are so far recognized and admitted to be correct and reliable, as to be found from time to time copied in the columns of the *Chronicle*, *Call*, *Alta*, *Bulletin*, *Post*, and other journals generally with due credit, but not always, and one thing is certain, that if those reports were not, or did not appear to be reliable, we should have heard from some of the "live journals" named, who are too keen in their pursuit of accurate information, to allow themselves to be misled by doubtful statements from unreliable sources. The fact that our reports have included all that appears on the books of the Spring Valley Water Works, with thirty-three additional, certainly entitles us to preferred credit for correctness. But as we have heretofore stated in our yearly summaries, it is altogether likely that, with all the care exercised, we may miss some, as some owners very unwisely prosecute the erection of buildings without architectural supervision, and the fact of such erections are only ascertained by the system of personal canvass of the city made by our reporters each month. Admitting this to be so, and taking into account the possibilities in this connection, the result would increase the difference in totals, as mentioned in this article, to perhaps twice the figure named, still showing, however, the nearer accuracy of our reports.

Pay for It, If You Want to Read It.

WHILE we are reaping a pleasing reward for the time, labor, and money expended in the publication of this journal, there is room for a large increase in the number of subscribers. There should be not less than ten thousand in California and the Pacific States alone. It is the only journal published west of the Rocky Mountains, in the building, sanitary, plumbing, and other similar interests, and not a single owner of real estate, nor a carpenter, or mechanic of any class, but should subscribe. Each monthly issue contains information and matter worth more than a whole year's subscription, and the high standing reached places it among the very best of class journals published. The fact that its original matter is reproduced in scores of journals of all classes, attests the value of its monthly contents, and the innumerable complimentary notices received, adds testimony to the fact that it is a recognized, valuable journal; and, as such, it should receive universal support. Those who have noticed its progress must have discovered the advance made in its every department toward that excellence promised in its earlier numbers. It has required many thousands of dollars and an immense amount of hard labor and sacrifice to bring about present results, and we certainly feel that we have a claim upon those in whose interest it is published, for financial aid and support. The fact that hundreds obtain access to its columns through the kindness of those who pay for it, is by no means creditable to those who practice "sponging," rather than pay the small sum of two dollars per annum, and receive it honorably. The position of "dead head" is by no means a nice one, and we trust that all those who have relied upon seeing it in "somebody else' office," or borrow it from subscribers, and all others, will send in their names and subscription amounts. It is a costly publication and should be paid for by those who read it.

IT is sagaciously hinted that to determine the value of building stone a ramble among the tombs is wise. In far fewer years than most people imagine, monuments decay.

New York Street Architecture.

A. CURTIS BOND.

THE COMPOSITE.

A RECENT writer in the *Pall Mall Gazette* claimed that brick when used in building exteriors was a subterfuge, a substitute for something more substantial and more in consonance with the weight of a house. Whether there is any force in this argument, or, as is more probable, whether it is merely one of the idiosyncrasies of an individual, brick has certainly taken an undeniable hold of the New York taste. Brown stone for a time, and a considerable time at that, was "the thing," and brick was considered too awfully ordinary; but people seemed to have tired of the once expressionless fronts of our aristocratic dwellings and have turned to brick as a relief, until finally it has become a fashion—the aim of every man and thing, for when it becomes fashionable its reputation and its fortune are secured, temporarily at least.

In most instances this adoption of brick has led to the construction of buildings suited to that sort of material, and the Queen Anne style has naturally been much in favor, for in this, probably of all others, the brick shows its decorative qualities to the very best advantage.

Red brick is warm in appearance, an excellent offset to our variable (and, alas, too often invariable) weather; it is domestic, inviting, home like; a house looks more cheerful, more social, cosier in brick than in anything else qualified for use in the city: it gives one the impression that the people who live behind it are nice, quiet, hospitable folks (this impression is often an erroneous one, of course, but it creates a pleasant feeling for the moment), people that can be approached and talked to and invited over to the house to supper. While the great staring, blank stone wall gives a chilling sort of an idea as to those whom it harbors, throws out the suggestion that they are of the "set" and don't care particularly about increasing their circle; at any rate, have no desire to take you into it and then you shrug your shoulders and stroll out to the park and have a smoke, and your thoughts run in an uncomfortable channel, and you make up your mind that "the more you see of men the more you like dogs," or something of that character. This is my exaggerated opinion of brown stone, and I imagine others are beginning to entertain the same thought, for, as I have said, it is being displaced.

Instead of being a substitute, as is claimed by the writer whom I have just referred to, it seems to me that brick may more rationally be considered the fundamental building substance, the constructive element proper alike of the primitive and the modern house. As it is used and colored now, it may take on the appearance of terra cotta, and the fronts of some of our new flats, for example, are really unique in effect and frequently so in detail; the terra cotta panels and the apparently terra cotta ground word make the façade more than ordinarily showy, and, what is even better, permanent and lasting, for brick, among its other good qualities, possesses durability.

* * * * * *

In some places, antique cities and ancient villages one finds in wandering over Europe, they use tiles for the front of buildings; good, clear, shining tiles, tiles that are never dirty, for every shower washes them off and they look fresh and new as if they were just taken from the shop; no rust, no green deposit, no fading yellow, nothing to the end of time (for that particular building), but tiles, blue, yel-

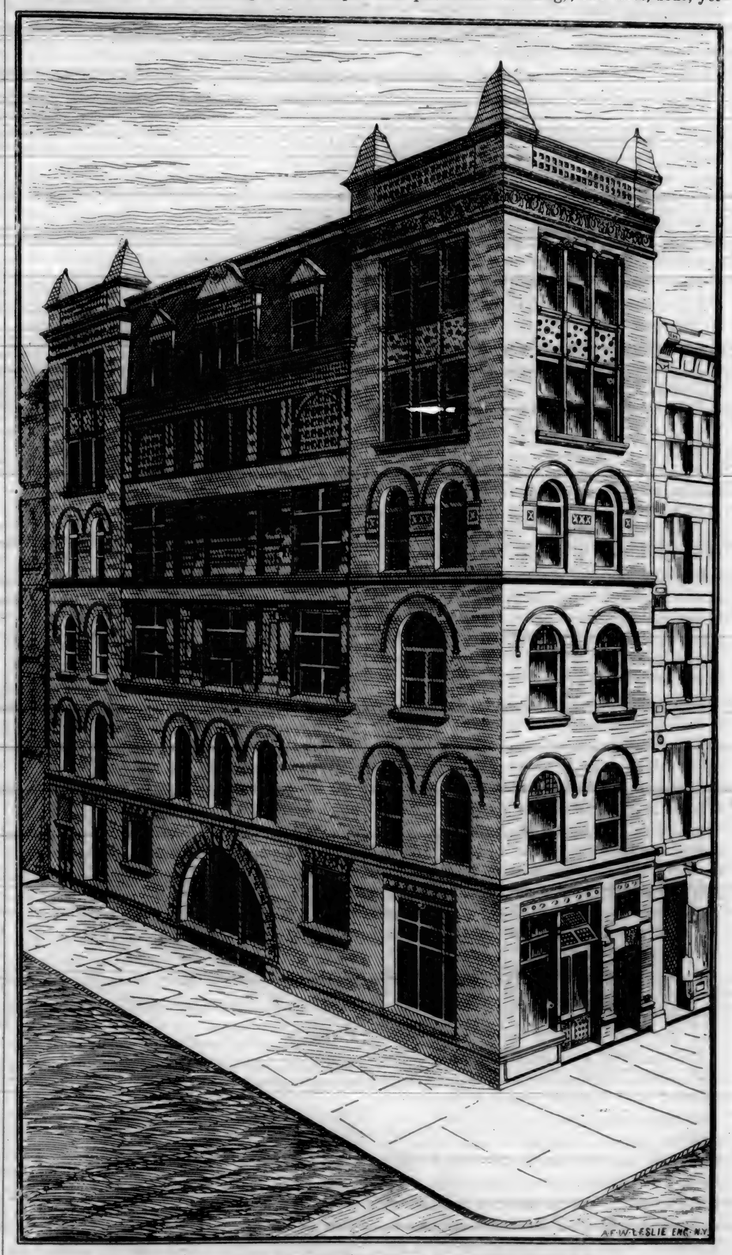

PLATE I.—NEW YORK STREET ARCHITECTURE.
Prepared for this Journal by A. Curtis Bond.

low, red, anything you please, first and last the same color, the same shade, the same tile. What a contrast these semi-civilized structures show to our streets! Painted bricks with the point scaling off, veneered brown stone and the veneer failing to adhere to its foundation, scagliola that looks moth eaten, stucco in a demoralized condition, and freestone with arabesques and scrolls worked upon it in mold. Why won't some courageous builder free himself from these horrible materials and try the effect of a tile front? It would require courage, perhaps, but I have an idea it would reward the attempt to introduce it, and the result, if adopted, would certainly be to vastly improve the appearance of our streets and detract somewhat from the chronic melancholy of our architectural countenances.

* * * * * *

As I urged the claims of brick and found in it all the apparent essential qualities of a constructive material, it would hardly do to desert it entirely in favor of tiles as my preceding paragraph would suggest; so I must own to a certain allegiance to glazed bricks whose history has had particular attractions for me ever since I saw the old market church in the city of Hanover, which is said to be the oldest example of glazed brick work in existence. It is said that prior to the fourteenth century the glazed brick was but little known, or at any rate was very little used; early in the fourteenth century, however, its employment became more general, and from that time to a comparatively recent day, it has been more or less an accessory in architecture. A number of spires built from glazed bricks are found through Germany, and one who has never seen the effect of these glistening, brilliant structures can hardly participate in my enthusiasm in advancing them.

"The durability of glazed bricks does not depend upon their color, but varies according to the composition of the glazing substance. Yet, as the composition of the glaze reacts upon the color, it has been noticed that the darker kinds are, as a rule, better preserved. In the composition of the glazing substance each producer varies the proportion of the component parts according to the quality of brick to which it is to be applied, and according to the method of burning which he employs." These words are quoted from the report of the Hanover Architects' Society.

I wish these few sentences of mine might be productive of some good, and tiles or glaze be adopted in the place of paint and stucco.

* * * * * *

The composite or eclectic, or whatever name the modern architect chooses to give it, has attained, and appears likely to retain, an unmistakable position among builders. Originally it gave the architect an opportunity for displaying his diversity of knowledge among the many differing and various styles that it was allowed, might be combined under this one general title; but as it has increased in popularity there has been given it a form somewhat distinctive to itself, and it may ultimately be ranked among the "orders."

The illustration accompanying our letter is an example of what may be termed New York Composite, and belonging to the most recent improvement of that character we can very safely accept it as embracing the latest and newest phases of the style. The building shown is of brick, with terra cotta trimmings, and the large square space on the side between the towers is painted a steel-blue, making a most peculiar and unusual, though by no means unpleasant, effect. The large windows in the upper part of the towers admit a fine light to two floors of architects' offices; the oval topped panels between the fifth story windows help to give variety to the general appearance, and in that way are most effective; the slabs between the windows of the third floor bear brass plates inscribed with the name of the building, the date of laying the corner-stone, and the names of the architects.

The building is known as "The Hartshorne," having been erected by Stewart Hartshorne, who has made himself more or less famous, locally, by the invention of a mechanical shade roller, that has probably brought about his ears more law suits and more litigation than almost any other one invention of any importance in the city. But it falls to the good fortune of some men to have a boom in this sort of free advertising that is no small element in their success. Those persons who are fond of tracing everything to its origin, tell us that the composite made up or composed of numerous other styles, was brought into being by the Romans when they were either originating or destroying everything on earth. They devised the form in order to show their dominion over all nations, most of these nations making use of one or the other of the component "orders," and thus being represented through its distinctive phase of architecture. The Romans heaped one above another, Tuscan, Doric, Ionic, Corinthian, until they completed a magnificent structure, and the composite though in some respects a nondescript, was, in others, the most beautiful of exteriors. Le Clerc writing of this style says: "It may with singular propriety be used wherever elegance and magnificence are to be united, but more especially in buildings designed to commemorate great and signal events, or to celebrate the corubine achievements of conquerors and legislators, inasmuch as the capitals or other ornaments may be composed of emblems and of allegorical representations."

Modern architects diverge widely from this model and have given us something more in consonance with the times.

AT a recent meeting of the Maryland State Board of Health, it was decided that hereafter sanitary conventions or meetings should be held at least once a year, under the auspices of the board, in different parts of the State, with a view to promote a general interest in sanitary science, the first meeting to be held in Baltimore on the fourth Tuesday in October, 1883.—*Sanitary Engineer.*

The Mechanics' Fair for 1883.

THE preparation now in progress by the managers gives assurance that the exhibition which will be opened in September next will equal if not surpass that of any preceding year. And we presume that the good judgment and business perception of all manufacturers, inventors, artists, farmers, merchants, producers and dealers in goods, wares, and merchandise of every class and kind, will lead them to see and appreciate the value and advantages of the opportunity thus offered to expose and popularize that which each may have for sale or public patronage; and this appreciation should stimulate a general emulation in display, and so render the exposition, as it deserves to be, a splendid success. And we hope that exhibitors will amend the rule heretofore practiced, and have their spaces filled and fully arranged upon the opening night. The neglects and tardiness which has heretofore prevailed, of quite a number holding back, and not completing their exhibits for several days after the opening, has materially lessened the interest of the public in visiting the fair during the first week. This should not be so, and as very many of our Eastern visitors are likely to remain among us until after the opening, we sincerely hope that the display upon the opening night will be essentially as grand in every particular as that of any other evening during the continuance of the fair.

San Francisco Chapter of Architects.

THE regular meeting of the Chapter will be held the first Friday in August, at which it is earnestly desired that every member shall be present, as the nomination of officers for the ensuing year will be the special business of the evening.

The beneficial influences of the Chapter upon the profession, in an individual and general sense, is an admitted fact, and this fact should stimulate to earnest effort on the part of every member, to assist in sustaining and increasing Chapter interests, and making it a power for good in the architectural profession. And the Chapter vacation season expiring with August 3d, it is hoped that every member will be present.

PRACTICAL CARPENTRY.

PRICE $1.00.

A guide to the correct working and laying out of all kinds of Carpenters and Joiners' work. Solutions of the various problems in Hip roofs, Gothic work, Centering, Splayed work, Joints, Hinging, Dovetailing, Mitering, Timber Splicing, Hoppers, Skylights, Raking mouldings, etc. This work should be in the hands of every mechanic. One of the features to which this book will undoubtedly owe its success, is the absence of those numerous formulas which serve only to confuse the ideas of so many workmen. Everything is written in a clear, concise, and practical manner, and its utility is brought within the grasp of those workmen who have not had the benefit of a school education. We will send the above work to any address upon receipt of $1.00.

Pacific Grove, Monterey, vs. Carmel River.

THE INTRODUCTION OF THE WATERS OF THE CARMEL RIVER THROUGH PACIFIC GROVE AND TO THE HOTEL DEL MONTE.

NESTLED at the foot of verdure-clad hills facing the beautiful bay of the same name, lies the quaint and ancient town of Monterey. Its old adobe ruins suggests to the pleasure-seeker, visions of scenes in the tales of the Alhambra. One is struck with awe as he mounts the deep-cut steps to the tower of the Old Mission church, and gazes on the work of those who lived more than a century ago. We linger but a moment to gaze on the ruins of the fast decaying Convent, and mentally wish that some philanthropist would enclose them for protection against the wear and waste of time, that future generations may look upon the work of the founders of this western country and note the progress of architecture from the rude adobe to the magnificent capitol of our State, and other more modern constructions.

Leaving the quiet, dreamy old town of Monterey, "where every person seems satisfied with himself, apparently believing the world is completed—living on in the dreamy self-satisfied consciousness that the spirit of progress is at an end," the pleasure-seeker presses onward to the beautiful Pacific Grove, passing numerous points and things of historic, and present interest,—among them the window in the old adobe at which Mrs. General Fremont sat while writing her descriptive letter of California; the first brick edifice erected in the State; the solitary and semi-sacred cross which marks the spot upon which the reverend pioneer fathers first planted their feet on the shore of the bay of Monterey, bearing the legend, "June 3rd, 1770"; the old fort with its one solitary gun keeping sentinel only over the dead silence of the crumbling bastions; the adobe in which the early Legislators first met in council to deliberate upon and frame the organic and legislative laws of the State; the little cove where the fishermen rest from their daily labors, and on to the beautifully wooded lane leading to the Grove where thousands yearly meet to enjoy the comforts of a delightful sea-shore resort; over and through which the pure ocean breezes spread themselves, while weary ones rest in the shade of a thousand trees, and countless songsters warble forth sweet music from the branches of the cypress, pine, fir, and other varieties.

There are but few prettier sights to be seen than the beautiful view presented in the approach to the Grove. The drive-way is grand, straight as an arrow, even the branches being trimmed that nothing may mar its symmetrical beauty, it presents a scene that at once engages the attention of even the phlegmatical observer. One can well say that nature is not at variance with art, nor art with nature, they both being servants of his Providence. Art is the perfection of nature, and in the beautiful drive before us, as we look upward and see the blue sky beyond the gently swaying trees, we say "tis very sweet to one who has been long in city pent to look into the fair and open face of heaven—to breathe a prayer full in the smile of the blue firmament." Thus it was with us, and arriving at the entrance of the retreat—"far from the gay cities and the haunts of men," we involuntarily paused at the sight before us. Lanes of fantastic cottages, gayly trimmed tents, romping, galloping children, nurses toddling the little ones in their arms,—surely we are but dreaming, or else our imagination is dwelling on an old oft-told fairy tale.

We rambled around the grounds, keeping always in view the object of our journey, and admiring the almost perfect sanitary regulations and conveniences of this beautiful resort. We say ALMOST because there has been but one thing lacking to make this place resemble that described in the opening chapters of the Book of Holy Writ, and that essential is a lack of sufficient quantity of pure water.

But master minds had long been engaged planning a remedy for the only defect that nature had imposed upon this quiet resort. Twenty miles away flows the beautiful Carmel River. For ages past, it has poured its limped waters into the bosom of the grand old ocean; but to-day, its currents have been brought under subjection, and in the future the Grove, Monterey, and del Monte will be supplied by its pure water. This river has long been noted for the almost chemically pure properties of its water. It is fed by numerous living springs and flows nearly its whole length over rocky ground. It is our pleasant task to describe how this water is brought to the Grove as pure as when it leaves the Carmel River.

The point selected by the engineer for the construction of the mighty dam that is to hold in its embrace the element without which all animal and vegetable life would cease, is about twenty-five miles from Monterey. To the uninitiated, a more uninviting place could hardly have been selected. Great credit is due to the intuitive ability of the * engineer, by which at a glance he could see how each and every obstacle was to be met and overcome. Engineering difficulties that would have discouraged any one with less energy and skill, were so studied and handled that the work in contemplation seemed to be directed as were the pyramids of old.

From the dam in the river to the reservoir near the Grove, the water is conveyed in iron pipes. The first six miles, eighteen-inch wrought iron pipes are used. In places the bluffs are so steep that holes are drilled in the solid rock, into which are placed heavy iron brackets, and upon these are placed the large pipe above mentioned. A covering has been securely fastened over the pipes to protect them from falling rocks.

At the end of the distance named the pipes are changed in size to fifteen-inch boiler iron. This is maintained for a few miles, when it is again changed to a twelve-inch cast iron pipe, three-fourths of an inch thick, and for the rest of the way the pipes are of this size and thickness. Much of the ground passed over is very rocky and full of clefts, as if some great force of nature had exerted itself to sectionize the ground by a system of deep cavities or gorges, many of which are bridged over; and in passing some of these clefts the pipe assumes the shape almost of the letter V. In such cases, at the bottom of each a cock is placed that the pipes in case of necessity may be cleaned of sediment, a cock is also placed at the apex, for the purpose of affording escape to pent up air.

That the cast iron pipe may be free as possible from danger, a trench about three feet deep is first dug in which the pipes are placed. After the latter has been tested the trench will be filled and the dirt thoroughly tamped. Trees near the route of the pipe line that show evidences of decay, have or soon will be cut down. A tree falling across the pipes will not be apt to break them on account of the depth they are placed in the ground. The more serious difficulty lies in the fact that the roots of a tree in falling may be under the pipe and thus lift it out of its bed, perhaps breaking one or more joints As far as human ingenuity can do so, this has been guarded against.

Our engraving shows the point where the pipe reaches the reservoir. This is situated about one-half a mile above the main entrance to the grove. Plate No. 2 shows the character of the work done before the reservoir was constructed. The ground was covered with trees, and it was no small task to cut them all down, grub out their roots, and clear the ground of rubbish. It is and has been the main purpose of those having this work in charge, to preserve the purity of the water, and in order to do this, every particle of vegetable matter, roots, etc., have been removed from the ground covered by the water within the reservoir. All the top soil has also been removed, and our engraving shows a body of men shoveling this top soil into a large pile to be moved to the outer edge of the dam.

It will also be noticed that a deep trench runs across the site of the dam. This idea and its fulfillment is one of the engineering triumphs of the master in charge. This trench is from twelve to sixteen feet in depth, and extends down to hard pan the whole length of the ground covered by the water when the reservoir is full. It is about six feet in width. This is to be filled with a solid wall of clay well tamped down. While excavating the pipe line, a large mass of clay was met with, and it almost seemed as if Providence intended it for the use to which it is applied. The clay is first puddled and then the ditch is filled with it, while hundreds of rammers are making it an impenetrable wall against the encroachment of the water. As this wall is gradually built up, the soft dirt on the inside is taken off and placed on the outer edge of the dam.

When finished the dam will be one hundred

* L. D. Norton, Esq.

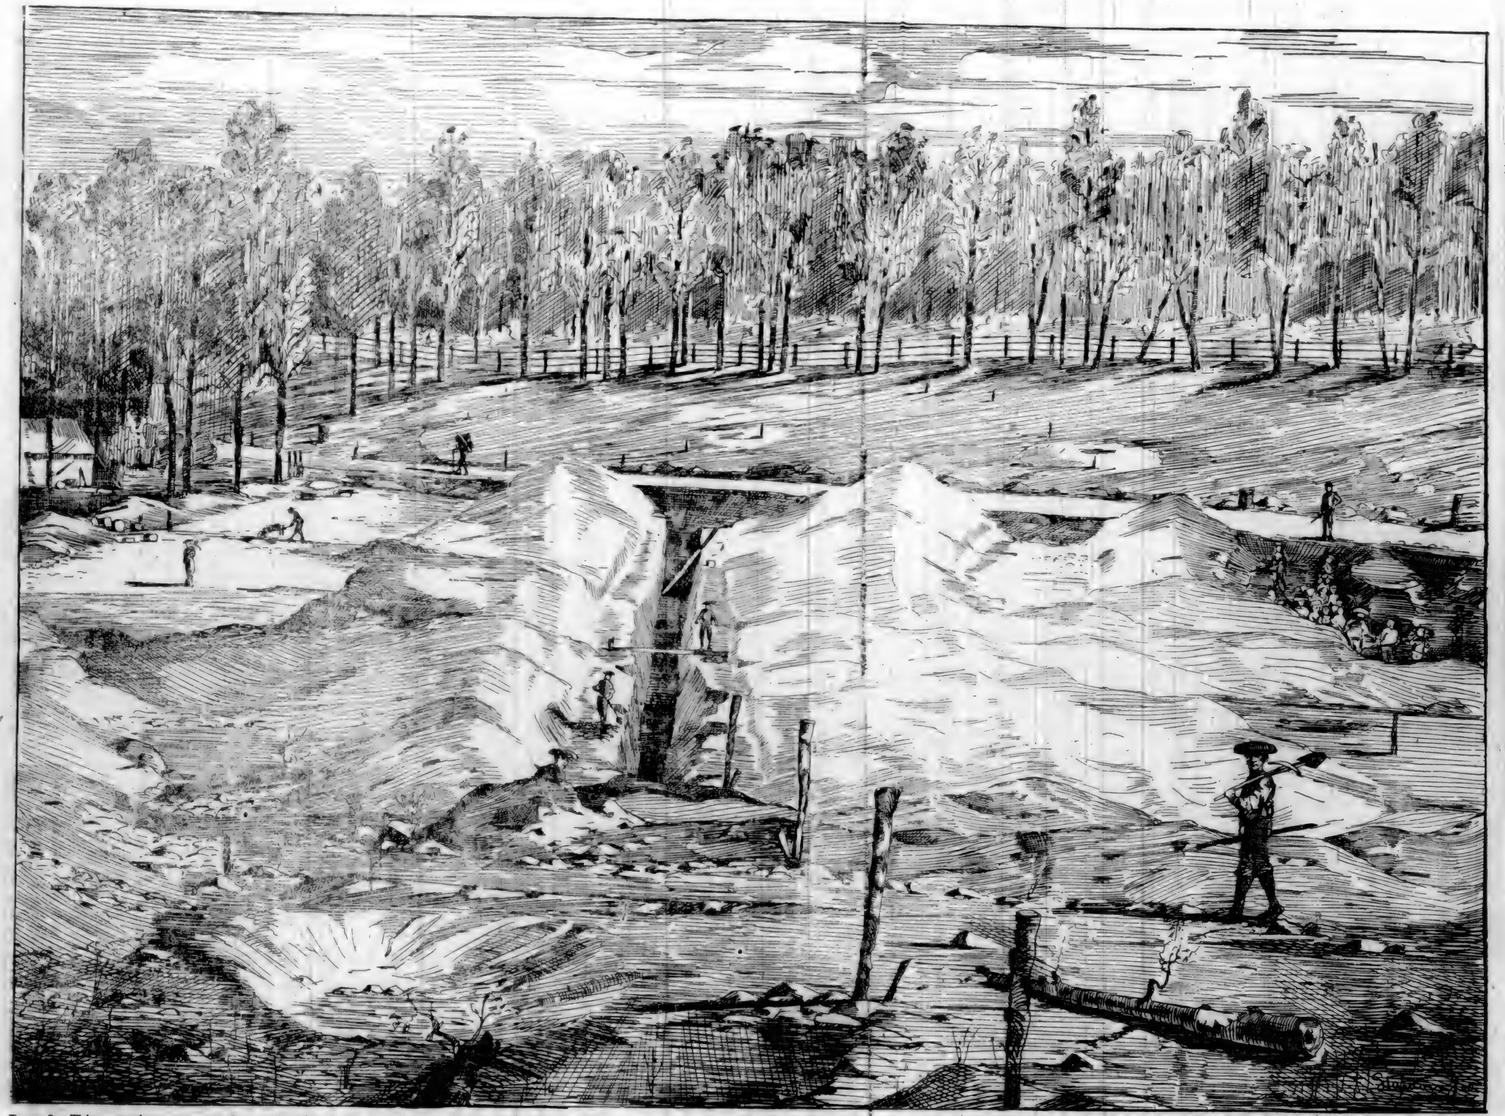

PLATE 2.—This engraving represents the construction of the new dam for the reservoir of the Pacific Grove water supply. The ditch shown is to run across the full length of the dam, and is to be filled with a solid wall of clay, as described on page 109.

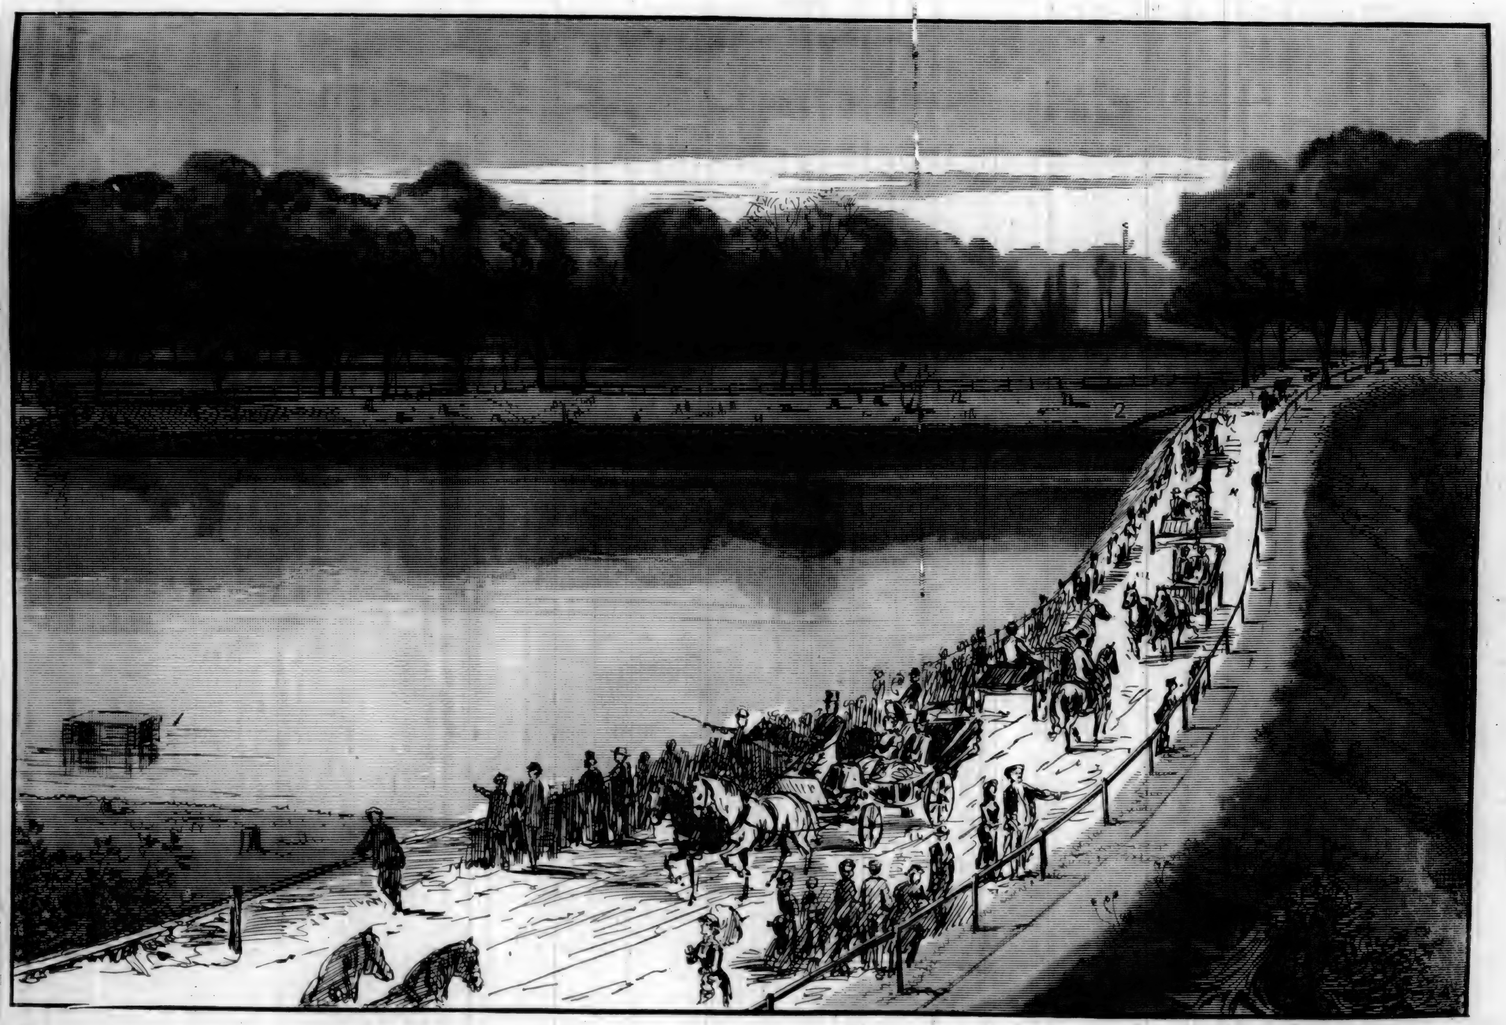

PLATE 3.—This engraving represents the dam when finished. It will be one of the prettiest drives of the many around and about Pacific Grove. See page 109.

and eighty feet wide on bottom, and thirty feet on top. Its height will be about thirty-five feet at the greatest point. The capacity of the reservoir will be about fifteen million gallons. The supply pipe will furnish one million three hundred thousand gallons daily, and should the supply pipe at any time be so damaged that it can not be used for a week or more, the water in the reservoir will be abundantly sufficient to supply all the country over which the pipes pass, for at least thirty days, and with reasonable use will last sixty days or more.

Much care has been exercised to prevent the formation of little shallow pools around the edge of the reservoir. Usually these are regular breeding places for mosquitoes and other insects. The whole outer edge of the ground encircled by the inclosed water will be sloped at an angle of about forty-five degrees, thus preventing the formation of stagnant water in shallow places.

From the reservoir the water is taken through a four-inch pipe over every portion of the Pacific Grove Retreat. It is the intention to change this size to a six-inch pipe whenever the demands of the grove require such a change.

From the description of the work now in process of completion, it will be seen that an abundance of pure water is guaranteed to those who seek the quiet precincts of the Grove for either health or pleasure. It will be greatly appreciated by those owning lots, as they can beautify their premises with flowers, trees, and shrubs, and have the great life-giving element at their very door. Another advantage greatly to be appreciated by those who love to drive over a fine road, will be, that the roads can be kept well watered. Tanks can be erected at a few different points, thus enabling sprinkling carts to keep the road in splendid condition between the Grove and Monterey.

We append a little sketch showing the present facilities for supplying the Hotel del Monte, which although it is but a small engine inclosed by a rude shed, is a source of much attraction to the many little ones who are amused at the click chuck music of the pump as it is worked by the engine; and the pleasure thus afforded to innocent prattlers, furnishes the subject of numerous childlike stories for mammas and papas.

Now that pure water is to be supplied in quantities abundant and sufficient for all purposes, to those who seek the pleasant retreats of Pacific Grove, Monterey and Del Monte—while the waters of the broad Pacific Ocean lash the craggy shores, and the far stretching, crystal sand beaches of the bay of Monterey, it is reasonably to be anticipated that the portion of Monterey County encompassed in this article will at once, or at a very early day, become the leading and principal resort in the State; not only of the resident population, but of the thousands who now, and the tens of thousands from all parts of our own and foreign countries, who will yearly visit this coast in search of the picturesque, instructive and pleasant things that so richly abound in all parts of California, and in the section of country under notice in a special manner. While grandeur of scenery and spots delightful for resting places during the summer months may be found in numerous other localities, we know of none which affords superior if equal advantages over the region under notice, with its land and ocean views, its splendid and numerous macadamized roads—unequalled by any other pleasure resort region—leading and winding through thickly studded wood, quiet groves and valleys; now exposing the smooth or ruffled bosom of broad ocean, now opening up extended views of hill and mountain scenery, and again closing in beautiful fertile glens and valleys, all combining to furnish food for the contemplative and appreciative mind with Nature's most perfect work in natural scenery.

Strength of Yellow Pine.

It is reported that a comparison of the relative strength of yellow and Norway pine was made at Dayton, O., with the following results: The specimens were dressed exactly one inch square, and these were broken in a testing machine by placing them on bearings, one foot apart, with the weight in the center. The southern pine had been air seasoned for two years and upwards, the Norway from a year to fifteen months. The weakest yellow pine broke at 736 pounds, the strongest at 1,102 pounds; average of eight specimens, 904 pounds. The weakest Norway broke at 501 pounds, the strongest at 790 pounds; average of ten specimens, 702 pounds, showing the yellow pine to be 28.7 per cent. stronger than Norway, and that a yellow pine sill 4x8 inches dimensions is equivalent to a Norway sill of 5½x8 inches, with the further advantage in favor of the yellow pine that it can be got much freer of knots and consequently stronger in comparison than these figures show, which are based on clear timber. Another test was made at a meeting of the Master Car Builder's Association, with the following results: Five pieces of each variety, one inch square and eleven inches between bearing points, were experimented upon, the pressure being applied in the center. The outcome showed strength of yellow pine at 500, 510, 500, 490, and 530 pounds breakage strain, or an average of 506; while Norway stood a strain of 620, 645, 730, 650, and 630 pounds, or an average of 635 pounds. These experiments do not appear to throw much light on the question of relative strength, and unless it can be attributed to the diference in seasoning, it is hard to find a satisfactory reason for such a discrepency—*Northwestern Lumberman.*

Wheeler's Patent Wood Filler.

This is by far the best article of its kind that has as yet been brought to our notice. One coat prevents any further absorption, hence the oil in subsequent coats of paint will stay with the pigments. It gives the wood a surface as smooth as ivory. We are pleased to announce that the Bridgeport Wood Co., manufacturers of the above Filler, have established an agency in this city, where any quantity can be had. Architects will do well to call for this Filler in their specifications.

It is said that from 95 to 98 per cent. of all the railroad locomotives in use in the British colonies were manufactured in the United States, and that all of the continental European countries have their roads equipped to a greater or less extent from the same source. Within the last ten years the exportation of railroad locomotives from the United States has aggregated $12,000,000 and the passenger coaches $40,000,000.

Sample Copies.

Hereafter we will forward no sample copies of this Journal unless the price, twenty cents for each number, accompanies the order.

Supplement No. 2.

Special Notice to Advertisers

We are now preparing our Mammoth Edition of

FIFTY THOUSAND COPIES

Of a Supplement of this Journal.

It will be 8 pages, each page 16x23 inches in size.

Pacific Coast Architecture.

Each page will be beautifully illustrated with designs exemplifying different classes of building in the styles of Architecture now prevalent on the Pacific Coast. Suburban and Country dwellings, City Residences, Cottages, with plans and explanations of the same,—in fact all kinds of buildings will be shown.

Mechanics' Department.

Special care will be taken to present to Mechanics all the new ideas in regard to framing buildings, rules by which all the various cuts in Carpentry are made, and items of information generally in regard to the Building Trade.

Distributing the Mammoth Edition.

Special arrangements are being made for the distribution of this Supplement. In order that a copy may reach all the *bona fide* residents of this State, we have divided it into several routes. First-class men have been engaged, selected especially for their ability to further the interests of the projectors of this enterprise.

To show how the distribution is to be made we will describe two of the routes. One man will leave this city in a buggy, taking a

Tour Around the Bay.

He will stop at every town and leave every resident, as far as practicable, a copy. Whenever convenient along the route, he will leave some amongst the farmers. By this means the towns of San Mateo, Redwood City, Menlo Park, Mayfield, Santa Clara, San Jose, Alviso, Newark, Centreville, Mission San Jose, Niles, Haywards, Eden, Alvarado, San Leandro, San Lorenzo, Alameda, and Oakland will be thoroughly supplied.

Another employee will proceed by rail to Modesto; after supplying that town, he will in succession stop at the towns of Ceres, Turlock, Merced, Athlone, Berenda, Madera, Borden, Fresno, and in fact every town as far south as Los Angeles. We will send by express the number we desire to have distributed in each town, so when our Agent arrives in that place he can proceed at once to deliver the number sent. In this way his time will be used to advantage.

Of course the main design is to

Increase the Circulation

of this Journal; and advertisers will please remember that all steps taken in this direction is so much to their advantage.

A Limited Space Only

will be given to advertisements. The columns will be about 3½ inches wide. A square will be the width of one column, by a depth of one inch.

A Uniform Rate

of $2.50 per square will be charged. No deduction for a space less than five squares. Special contracts made for larger spaces.

One Hundred and Six Reams

of paper, 480 sheets to the ream, of good paper have been secured, and we guarantee an actual edition of

Fifty Thousand Copies.

This is allowing 880 for wastage, but of course it will be much less than that number.

Oregon, Washington, Hawaiian Islands, and in fact this mammoth edition will be distributed all over the Pacific Coast and adjoining islands.

Particular Notice to our Eastern Advertisers.

We will not have time to carry on a lengthy correspondence in regard to the insertion of advertisements. The facts are just as we state. An edition of **50,000**. A uniform rate of **$2.50** per square. There will be no choice place as all pages will be equally interesting. The perfect system by which we distribute this Supplement will ensure the notice of your wares being seen by more than

One Hundred Thousand

residents on the Pacific Coast. The fact that this Supplement will be under the superintendence of the Business Manager of this Journal, is a sufficient guarantee that all the designs contemplated will be faithfully carried out.

Please Notify the Manager

of the California Architect and Building News immediately the space you will require. Eastern advertisers not personally known to us, must send either a post-office order for the amount of their ad, or else send us references to parties in this City.

Address **GEO. H. WOLFE,**

Business Manager California Architect,

240 Montgomery Street, San Francisco.

Solid and Hollow Iron Columns.

A confusion of ideas is sometimes found among practical men respecting the comparative strength of solid and hollow pillars. One hears it often said, for instance, that a hollow pillar is stronger than a solid one. Now this is, as one able authority has pointed out, not absolutely the case; it is perfectly true that comparing the strength of two pillars of the same height and diameter, one solid and the other hollow, that the latter has the advantage of being economically stronger. The fact is, the solid column is stronger than the hollow of the same external diameter; but the lesser area is more effective than the greater, because the central portions of the solid pillar are less useful in resisting the bending force than the metal in the circumference of the hollow pillar. But if the quantity of material in both the solid and hollow pillar of equal height is the same, the hollow pillar is by far the stronger. A simple geometrical construction will enable any one to understand this fact, by enabling us to proportion a hollow column of the same area as that of a solid one, by one of the diameters being given. It is shown, in fact, that hollow columns of the same area of metal as a solid one, may be made to any larger diameter, their strengths increasing proportionally till a limit is reached by the shell of the metal becoming too thin to insure a sound casting. Taking an example from Downing's work, a hollow pillar 9 inches in external diameter, having an internal diameter of 8.062 inches, and a thickness of 4-7 inches, or about one-half inch, is five and one-half times stronger than a solid pillar with the same quantity of metal. A thickness of one-half inch may be regarded as a practical limit in manufacture.—*Building News.*

Prevention of Fading in Shop Windows.—The Swiss *Gewerbe Blatt* recommends a remedy for an evil which drapers and many other shopkeepers have long experienced, namely, the fading or bleaching of many kinds of colored articles when exposed in the shop windows. The authority quoted says that this fading or bleaching is brought about only by the white rays of the sun's light, and, where it occurs, it shows that the glass is more or less perfectly colorless. It is found that if, instead of such colorless glass, the window panes consist of glass which is slightly yellow, the bleaching or fading process is prevented. Where the glass is colorless and cannot be replaced by slightly yellowish tinted glass, the desired effect may, it is said, be produced by simply giving the panes a coating of copal varnish.

New Catalogue.

We will mail a copy of our new catalogue of designs for Crestings, Fences, Finials, Posts, and wrought-iron work of every description, upon receipt of a letter from parties desiring them.

Bigelow, Sims & Morris,
Western Iron Works.

☞ Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas, send us a sketch of them and we will make the cuts.

Eds. Architect:—In your really good article on the Pyramids, you failed to mention one very important fact, which is this:—It has been proven beyond a doubt that the Great Pyramid was covered from top to bottom — over the "steps" with *polished granite.* Now to say nothing of the difficulty of putting this on up to the apex, the question presents itself, "How did they get that, the crown, the key of the whole structure, in its place." This is a very difficult problem to solve. Of course I do not pretend that the above is an original question, but it may meet the eye of some one who has given the subject much study, and I for one would like to know the latest truths that the researches of science have made. Yours truly, J. B.

Cleaning Screws from Rust.—Rust can be removed from small screws, etc., that are too small for holding against an emery-wheel, by attrition. Take, say, one pound of screws, and place them in a box; a cigar-box will do. Put a small quantity of oil on them, and shake for another minute or so, and then sift the sawdust from the screws in a fine sieve, when the screws will be found to be as good as new.

Stained glass windows can now be made at home by attaching to the plain window, in artistic combinations, the clippings and waste from the bench of the glass-cutter. There is a little wheel sold for something less than a dollar which will cut the glass, and with this the amateur can shape the pieces to suit himself.

A decided revival in the demand for mahogany is reported in the English markets. The wood is increasing in favor generally, and is much desired in cabinet work. Mahogany furniture is largely in stock. Figured logs are less desired, but the wood of rich color is greatly sought after.

Imitation of ground glass can be easily produced by dissolving about two table-spoonfuls of Epsom salts in a pint of lager beer, and painting the glass with the mixture. When it is dry the glass will appear as if frosted, and the effect is very satisfactory.

"Modern House Carpenter's Companion." Price $1.00.

Chimneys.

AMONGST the lost arts we must, it is feared, include the art of building chimneys which will fulfill their proper function; and the smoke nuisance not only poisons the air we breathe, and undermines our health, but it defaces our architecture into the bargain.

It is very much to be suspected that the building of chimneys is left in a great measure to chance, or they would not be so bad as they are. The conditions which should be observed to secure success are well known and are easily obeyed. First the chimney-stack should discharge at as high a level as convenient so as to ensure that the outer column of cold air shall have a marked preponderance over the equal column of warmer and therefore lighter air in the flue. The modern custom is to cut off the chimney-stack as soon as it shows itself above the roof. The additional height is quickly made up by the substitution of a zinc tube, and shows that the original error lay in robbing the stack of its due altitude. Secondly, the area of the flue is almost always in excess of the requirements. The traditional 14 in. by 9 in. was, as has often been pointed out, determined by the fact that the climbing boys who swept the flues could not ascend safely in less space. But with the disuse of boys for this service the reason for the old dimension of the flue vanishes. The late Mr. Cubitt found, as the results of experiment, that a better size was 9x9 inches, and that this was enough for all ordinary purposes. For many years the writer has adopted this form of flue and his experience of its efficacy exactly agrees with Mr. Cubitt's.

Thirdly, the outer casing of chimney-stacks is generally too thin. A half brick is the usual allowance, not "of the best material and workmanship." Now, we know that this is no protection against cold and wet, and that if the upper part of the chimney is cooled the ascending current is checked in consequence. The writer never on any account employs less than nine inches in such a situation, and he is confident that nothing less should ever be allowed if the draught of the flues is to be satisfactory.

And fourthly, the fire is too often quite unprovided with air from the outside, so that the heavier column spoken of above is not brought to bear on the base of the lighter one in the flue, and a sluggish action at the best is the result. The builder who is anxious that his flues should "draw," should be careful to provide a copious supply of fresh air in the region of the fire, and this can be done without draught by a modification of the expedient which, though a very old one, is usually associated with t e name of Mr. Tobin.

With the above precautions it is not probable that any trouble will arise from smoky chimneys, but it must be owned that sometimes the evil is met with in spite of every precaution. The "best laid schemes o' mice and men gang aft agley," and the action of smoke from an open fire is now and then, to say the least, capricious, and often baffles all our best endeavors.

This is a difficulty which should be resolutely faced, and if some form of cowl is inevitable it is the architect's duty to take up its design. If there is one characteristic which more than any other distinguishes the builders of past time from their modern *confreres*, it is the frankness with which they accepted, and the skill with which they turned to artistic account, the necessities of their time one by one as they arose. Evasion and subterfuge were alike undreamed of in their philosophy. They set themselves without hesitation and without reserve to their task of rendering comely whatever was found to be necessary or useful. There is not a beauty in the old work but is the result of the judicious treatment of what was at first a difficulty, and features which we copy long after the original necessity to which we owe them has ceased to exist, survive simply as evidence of this special and peculiar gift of our ancestors. The faculty was so complete and universal that its exercise seems almost like the result of instinct, and thus to lose its merit as art.

Amongst the many instances of the directness and certainty with which the early builders developed to the utmost the artistic possibilities of every new problem as it presented itself, we may cite the domestic chimney itself. The hall *louvre* was always a picturesque feature, and we should regret its abandonment in favor of the fireplace, but for the various and picturesque forms which the architects devised for the chimney-stack which replaced it. If we trace the history of this feature from its first appearance as a single shaft with side piercings at its summit until its glorification under the Tudors, one cannot fail to be struck with the ingenuity, the perseverance, and the versatility of its designers.

Hitherto the modern architect,—in face of the enormous probability that as soon as his building leaves his hands it will be disfigured by some sort of smoke-extracting apparatus,—has been quite careless as to what shape such apparatus shall assume; and there is something almost comic in the *sang froid* with which, after taking infinite pains about the design and details of every other part of his work, he leaves to those who care nothing about it the task of crowning it with an array of cowls.

The conclusion at which we are compelled to arrive is that although by care we may very considerably diminish the necessity for cowls or some cognate contrivance, cases will arise in which they are indispensable, and therefore they should form the subject of the architect's attention. Here is a new field for the exercise of whatever skill in the art of design is left amongst us, and we would suggest the matter as a fit one for the Institute prizes. In making a serious attempt to devise a suitable form for a necessary adjunct of our buildings we should be following the steps of the architects of old who never shirked an opportunity of the kind. Whether our endeavor should be attended with the success which invariably waited upon the efforts of our predecessors it would perhaps be rash to predict,—but at any rate the attempt should be made.— *The Builder.*

High Buildings and Fires.

THE increasing tendency of land owners and builders in large cities to utilize the ground area as much as possible by erecting lofty buildings, requires some commensurate means to prevent fires and to stay their progress. Our best steam fire engines are wonderful improvements on the old time hand engines, and they can force an unbroken stream of water in round, solid column for a considerable distance from the nozzle, unless exposed to a high wind or the direct heat of a raging fire. But these adverse conditions often exist and turn the water column into diffused spray, or dissipate it into mist or vapor, when most of its effective force is lost.

Recent experiments, however, suggest that if the force of the engine could be exerted on a confined column of water rising vertically to the roof, sufficient power would remain in the impulse from the engine to deliver streams of solid water over the area of any ordinary city building. A steam fire engine was recently tested which threw water 156 feet horizontally from a one-inch nozzle attached to a 2½ inch hose running 2,700 feet on a level and 200 feet above the engine. In this instance a very large column of water was made to deliver a moderately small column at a great height above the engine; but by the employment of two or more engines on the same hose, by means of the two-way or the four-way butt, a result may be reached which will place the roofs of the highest buildings under the control of the firemen.

This can be effected by a fixed stand pipe attached to the building so as to be easily reached by the firemen from the street. This stand pipe is, in effect, a prolongation of the ordinary engine hose, and the nozzle, with a convenient length of handling hose, may be attached to the top of the pipe, or to an opening on any floor.—*Scientific American.*

BRASS work that is so dirty by smoke and heat as not to be cleaned with oxalic acid, should be th oroughly washed or scrubbed with soda, or potash water, or lye. Then dip in a mixture of equal parts of nitric acid, sulphuric acid and water; or, if it cannot be conveniently dipped, make a swab of a small piece of woolen cloth upon the end of a stick and rub the solution over the dirty or smoky parts; leave the acid on for a minute and then wash clean and polish.

Important to those Receiving this Journal.

Should this Journal be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

Paint for Floors.

A PAINT for floors, which economizes the use of oil colors and varnish, is described in the German technical press as having been composed by Herr Mareck. It is remarked that this paint can also be used on wood, stone, etc. For flooring, the following mixture has been found applicable: 2⅛ ounces of good, clear joiner's glue is soaked over night in cold water. It is dissolved, and then is added (being constantly stirred) to thickish milk or lime heated to boiling point, and prepared from one pound quicklime. Into boiling lime is poured (the stirring being continued) as much linseed oil as becomes united by means of saponification with the lime, and when the oil no longer mixes there is no more poured in.

If there happens to be too much oil added, it must be combined by the addition of some fresh lime paste. For the quantity of lime previously indicated, about half a pound of oil is required. After this white, thickish foundation paint has cooled, a color is added which is not affected by lime, and in case of need the paint is diluted with water, or by the addition of a mixture of lime water with some linseed oil. For yellowish-brown or brownish-red shades about a fourth part of the entire bulk is added of a brown solution obtained by boiling shellac and borax with water. This mixture is specially adapted for painting floors. The paint should be applied uniformly, and is described as covering the floor most effectually, and uniting with it in a durable manner. But it is remarked that it is not suitable for being used in cases where a room is in constant use, as under such circumstances it would probably have to be renewed in some places every three months. The most durable floor paint is said to be that composed of linseed oil varnish, which only requires to be renewed every six or twelve months. It penetrates into the wood and makes it water resisting; its properties being thus of a nature to compensate for its higher cost in proportion to other compositions used for a similar purpose. Its use is particularly recommended in schools and work rooms, as it lessens dust and facilitates the cleaning of the boards.—*The Builder.*

Scarfed Joint.

WHAT is meant by the term "scarfing," applied to wood or metal in making a joint? *Ans.*—It is often required to unite two pieces of metal or of wood, in such a manner that the joint shall not be thicker than the rest of the piece when joined. To make a secure joint, however, it is necessary that the ends of the pieces should lap somewhat, and to avoid the extra thickness, the edges that are to be joined are beveled off, or "scarfed," so that when the edges so beveled are laid together by overlapping, the two pieces have the same thickness. Such a joint is called a "scarfed" joint, or lap joint; and the operation is called "scarfing." The manufacture of lap-welded boiler tubes affords a good illustration of forming a scarfed joint with metal, both edges of the "skelp," or plate, that is to form the tube being beveled preparatory to passing it through the forming die. In carpentry it is not necessary that the edges of the pieces of wood to be joined should be beveled; but any method of joining together two pieces of timber, by bolting or nailing them together transversely, so that the two appear as one, is called "scarfing," and the joint is called a "scarf."— *Wood Worker and American Lumberman.*

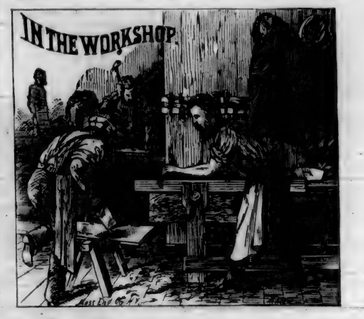
PITCH PINE.—Pitch pine is increasingly used all along the west coast of France, not only for parqueting, but in building. The American pitch pine flooring has been ascertained to have an advantage over that from the north of Europe—both costing nearly the same—which consists in its great durability and freedom from knots, giving it a much finer appearance. The French demand, it is expected, will grow large, while there is considerable consumption in Spain.

A WRITER says: Wood-workers are well known to be peculiarly liable to accident in the pursuit of their trade. Of course the keen edges and the swift-running machinery with which they have to deal, render their occupation a dangerous one, but I think it is safe to say that nine-tenths of the accidents can be fairly attributed to carelessness pure and simple. One proof of this is found in the fact that the larger part of the sufferers are not young and inexperienced hands, but those in whom familiarity has bred contempt.

SEVERAL kinds of hardwood lumber are gradually coming into use, which, a few years ago, were unnoticed. Beech is one of them. It is cheap and abundant, while the more popular hardwoods are becoming comparatively scarce and consequently high-priced. Beech has a fine grain, is quite durable, and is used in the manufacture of school and church furniture, chairs, and to a certain extent in furniture. The red variety has a handsome appearance, and can be made to imitate cherry.

THE *Art Amateur* for July contains an admirable and copiously illustrated article on "The Theory and Practice of Pen Drawing," and is alone worth the price of the number to the many who are interested in this humble but useful art. No one interested in art should fail to examine the July issue of this excellent magazine.

IN the Olympia District, W. T., a yoke of oxen for logging purposes costs as much as a span of horses —$350, and the demand exceeds the supply. Hay costs $30 a ton, chopped feed $35, and wages of men $68 to $100 a month.



We will be pleased to receive for publication in this column items of information in regard to practical ideas connected with the mechanical part of the building trade.

EDS. ARCHITECT: In your September issue, 1882, you illustrated the various scarfs or joints used in splicing timbers. You fail, however, to give one that can be used when the timber is only a little long and a short splice is required. The following cut which I send you will explain itself. It is much used in the East when the timber, in length, will not justify the use of the long joints shown in your article of the date mentioned.

You also say that "in every splice, no matter what the shape may be, there should be bolts through the joints securely fastening them together." In the accompanying illustration you will notice that a very strong splice can be made and no bolts whatever are needed. Yours, etc., E. B. R.
Portland.

We thank our correspondent for the above suggestions. We do not agree with him however, that the splice referred to is just as strong without a bolt. It is a very difficult one to make and have the parts fit perfectly, and unless a perfect fit was made, the joint would be a very poor one without being held together by bolts.

EDS. ARCHITECT: Please give me a rule by which I can find the number of studs required around the outside of a building, placed sixteen inches from center. S. R. T.

FIRST get the exact measurement of the outside of the building in feet. Take three-quarters of this amount and add one stud for each corner and angle, and one for each opening. Plates and gable studding are to be added extra. A rough and ready rule is to allow one stud for every foot of the outside measurement of the building.

"COTTAGES AND VILLAS." Price, $6.00.

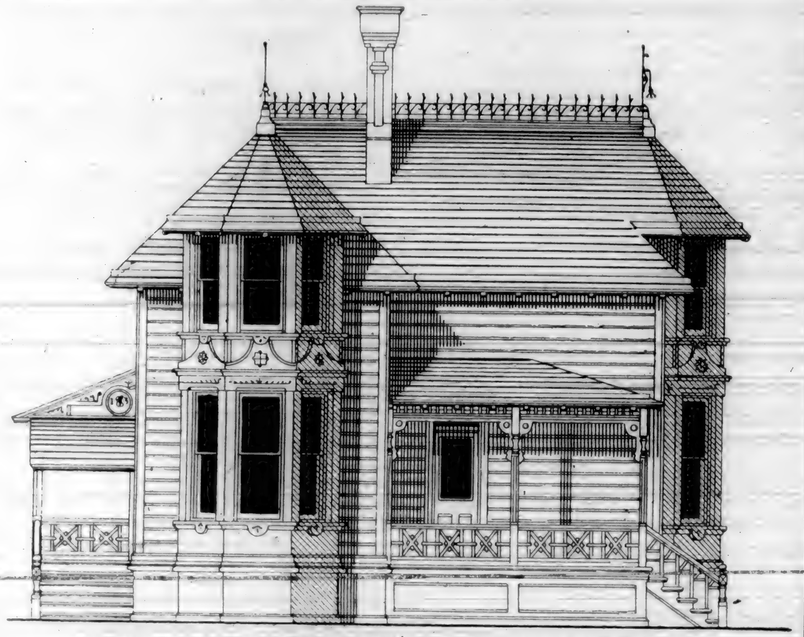


PLATE 4.—A SUBURBAN DWELLING COSTING ABOUT $3,000.

The Other Side.

[We admit the following communication to our columns for the single purpose—as far as its references and inferences go—of showing in what manner, and to what extent skilled and unskilled labor has been and is affected by the acts and successes of the railroad companies. We leave the vexed question of regulating freights and fares—direlict commissions, &c., to the tender!! mercies of the general press.]

STRANGE as the announcement may be to the average man, yet the fact remains that there are two sides to every question: the one idea, and one-sided creatures who foam over and fill the daily press with froth when discussing the railroad question in this State, seem to have forgotten, if in fact they ever knew this general proposition. Judging from their wild statements we are living under a tyranny worse than that of the Czar of all the Russias, —our State lying prostrate under its iron heel, and all enterprise heavily handicapped by its remorseless grasp, etc., etc., etc., *ad infinitum*—while strange again is this fact, that the men who raise this howl of anguish, and thousands who join in it, never pay one dollar for freight or passage over this terrible road, but feeding daily at this miserable mess of prejudice, ignorance, and brainless nonsense, they gradually come to believe that they are the most down-trodden people on the earth's surface, and raising their hands in holy horror they cry, Down with the magnates (*magnates* by the way is remarkably effective), and howl all the louder in hopes that the noise may become so obnoxious to the railroad people, that they may be induced to offer them a little coin to stop their miserable wail.

Now we wish to state a few facts and ask fair-minded men and women to give them their full weight in making up their minds on this important question. First—The large number of gentlemen employed by the great Railroad Corporation (hirelings, see daily press) include some of our most active and useful citizens, who take as much pride in the prosperity of this State as any portion of its inhabitants. And being as a rule well paid for the services they render, in return are faithful in the performance of their duties; at the same time obliging and courteous to those who transact business with the road, comparing most favorably in this respect with the working force of any Eastern corporation.

Second—The immense sums of money expended in this city and State, giving employment to thousands, encouraging home manufactories, and quietly but surely adding to the substantial prosperity of the Pacific Coast.

To call attention in detail to part of this constant outlay of money, we would cite the millions spent on the palaces on California Street Hill, the construction of which employed for several years hundreds of our best mechanics at the highest rate of wages, and whose beauty and splendor are the pride of every true citizen.

The very large expense incurred in building the California Street Cable Road, the efficient manner of its equipment and daily management; also the large amount of property enhanced in value by its construction.

The millions now being expended on the Market Street Cable system, sparing no expense to secure a roadway that shall last, run smoothly, and be a continual source of pleasure to those who patronize it. This first-class road with all its branches will be one of the chief features of our city, its equipment and management the very best, while property all along its far-reaching lines has advanced, and will still more advance in value, giving promise of the erection of hundreds of new buildings as soon as it is completed.

The million and over spent upon the mole and new depot on the Oakland side, which is unsurpassed by any ferry company in the United States, and giving security and convenience to the thousands who use it daily.

The extensive improvements at Benicia and Port Costa, including the construction of the mammoth ferry boat *Solano*, with the slips, warves, and landings, all of which involved a large outlay of money which also found its way into the hands of our best mechanics and laborers.

The purchase of seven thousand acres of land at Monterey, building the Hotel del Monte, laying out and beautifying the surrounding grounds, macadamizing twenty-five miles of roads through the most picturesque portion of the county, so that all the principal points of interest can be reached by tourists with pleasure and comfort; buying the great Los Laurrelles Rancho with its superior water privileges from the Carmel River, constructing substantial reservoirs and conveying the water some twenty miles in iron pipes twelve, fifteen, and eighteen inches in diameter, so as to afford an abundant supply of pure water for the Hotel del Monte, the surrounding country and the well-known summer resort by the sea, Pacific Grove. Enlarging the grove, erecting new buildings, and sparing no expense to make both places the most attractive resorts on the coast; advertising them in the most thorough manner throughout the Eastern States and Europe, so that the Hotel del Monte, with its many attractions is as well known as any similar resort in the world, bringing hundreds of wealthy and enterprising men to California, thereby calling attention to the resources of this State, where such golden opportunities await all who have either capital, brains or perseverance.

In the matter of advertising alone the railroad people have done more to make the advantages of this State known than anything that has been done for years.

The great faith, good judgment, and indomitable pluck that induced the managers of this corporation to project a line across the wilds of Arizona, New Mexico, and Texas, reaching to the Mississippi and New Orleans on the Gulf, spending millions of hard coin in an investment that was open for all the capital in the land to enter, but which lay dormant until the magic touch of our California railroad managers made it spring into life, thus making the far distant mines of silver, gold, copper and other minerals accessible to our people, and adding untold wealth to our Nation and State, making an outlet for the many products of this great commonwealth, and looking to direct communication with Europe at an early day. All this and much more being the result of the far seeing policy inaugurated by these terrible despots!!!

Thus in part only have we glanced at the great enterprises carried on so successfully during the past few years, and we leave it to all fair minded persons to consider if it is not time to give credit where it is due, and to stop this daily abuse of men who have shown such great ability to make money, and who have spent it lavishly for the improvement of the city and State where they reside.

Much more might be said, as the subject is far from being exhausted, but believing that the time is coming when the intelligent people of this State will refuse to be led any longer by a press that only cries "down with the railroad and its management," so that it can foist some favorite into power or fill its own pockets, we leave the subject, hoping that we may have said something that may hasten on the reign of justice and harmony.

Home Courtesies.

SINCE we presented the readers of this journal with its new dress, and in an enlarged form, we are more than pleased with the evidences of good-will shown to us by the editors of our California exchanges. And for the first time since we have published this journal we print a few kindly notices that have appeared in various papers, in regard to the evidences shown by us of increasing prosperity on our part. Many notices have appeared from time to time in papers published all over the Pacific Coast, but we have refrained heretofore from quoting them in our columns, and those found below are now given to show our Eastern readers the opinion entertained of us by our own co-workers in the journalistic vineyard.

THE *California Architect* has become one of the handsomest periodicals on the Pacific Coast in its new make-up, and is worthy of the support of every person connected with building operations in any manner whatever. We are pleased to see it giving such unmistakable signs of success.—*Commercial Herald.*

THE *California Architect and Building News* is decidedly the best publication of the kind in the West, and should be in the hands of every architect, contractor or carpenter in the country. Each number contains all the latest building news, and intelligent discussions of matters of interest to builders, besides from four to six pages of designs for buildings suitable for both city and country residences, together with ground plans and details. We have watched the progress of this excellent periodical and find that it is steadily increasing in interest and usefulness. The subscription price is but $2.00. The publication office is 240 Montgomery Street, San Francisco.—*Fresno Republican.*

THE June number of the *California Architect and Building News* is far ahead of any previous issue. It is printed upon better paper; contains some eight pages more matter; is more extensively illustrated than ever before; and in letter press is up to the highest standard of works of this class. The ARCHITECT, as it is familiarly known, is sound in all its departments. It is carefully and judiciously edited; always truthful, clear, and unbiased in its statements. Aside from its merit as an Architectual Journal, it is also emphatically the "mechanics own paper," and richly merits the standing it has attained.—*Alameda Encinal.*

WE have received the *California Architect and Building News* for June, and we feel that it is nothing more than justice that we should call attention to the merits of the publication, and recommend it, especially to all engaged in any of the building trades, or in the supply of building materials. The *Architect* is very neatly printed and the contents such as must be of interest and value to all who build, own, or live in houses, and that includes pretty much everybody with sense enough to go in when it rains.—*Hayes Valley Advertizer.*

THE *California Architect and Building News* for June comes to us with a new dress and enlarged form, an indication of its popularity and merited patronage. We wish it continued success.—*Petaluma Argus.*

EVERY carpenter and builder should subscribe for that excellent journal, the *California Architect and Building News.* The article on the pyramids in the June number was alone worth the price of subscription. The illustrations of plans for dwellings are excellent, and no carpenter can afford to miss the useful information given in each article.—*Cloverdale Sentinel.*

THE *California Architect and Building News* for June lies on our table. It has come out in a new dress and in an enlarged form. This monthly journal is becoming a very potent factor among our architects and those who intend to build. It is well conducted and filled with articles that are of great importance to all who are interested in the building progress of our city and State. The number before us is specially complete and interesting.—*Mission Local.*

THE *California Architect and Building News* for June is on our table. It is one of the best publications of its kind in the United States, and we are glad to learn that it is meeting with success. Every architect, carpenter, and builder should subscribe for it.—*Riverside Press.*

THE June number of that splendid publication, the *California Architect and Building News* has been received. Its monthly plans alone are worth more to builders than the price of subscription, while its sanitary suggestions are of value to every one.—*Watsonville Pajaronian.*

IT is with pleasure that we note the great evidences of thrift and prosperity possessed by the editors of the *California Architect and Building News*, as shown by their enlarging their journal, and at the same time donning a complete new dress. The June number is especially interesting. The article on the Pyramids should be read by every one; and there is not a mechanic in the State that should fail to subscribe, now that Part Two of the "Steel Square and its Uses" has been commenced. It is emphatically the representative of the building interests of this coast. We are especially pleased with the progress of this journal, as one of its editors for a number of years resided in this town, and we want to lay claim to our share of literary personages, whose minds have been partly trained in our beautiful village. Success and long continued prosperity to the *California Architect and Building News.*—*Healdsburg Flag.*

THE June number of the *California Architect and Building News* contains the most beautiful elevations and plans we have yet seen in that journal. This journal is improving in its engravings as well as its reading matter. No live mechanic or head of family should be without a copy.—*Santa Rosa Republican.*

THE *California Architect and Building News* is a monthly publication published by the S. F. Architectural Publishing Co. It is a useful publication to carpenters and builders generally, and contains well executed drawings of cottages and country residences, with plans of the different floors, besides a great deal of information to the architect, builder, and farmer. In its new dress and enlarged form it presents an appearance not excelled by any journal of its class in the United States.—*Mariposa Gazette.*

THE *California Architect and Building News* is getting to be a valuable and very interesting publication and is cordially recommended to our building trades. It has lately donned a new dress, and in typographical appearance and the ability displayed by the editors, it takes rank amongst the best of our scientific journals.—*St. Helena Star.*

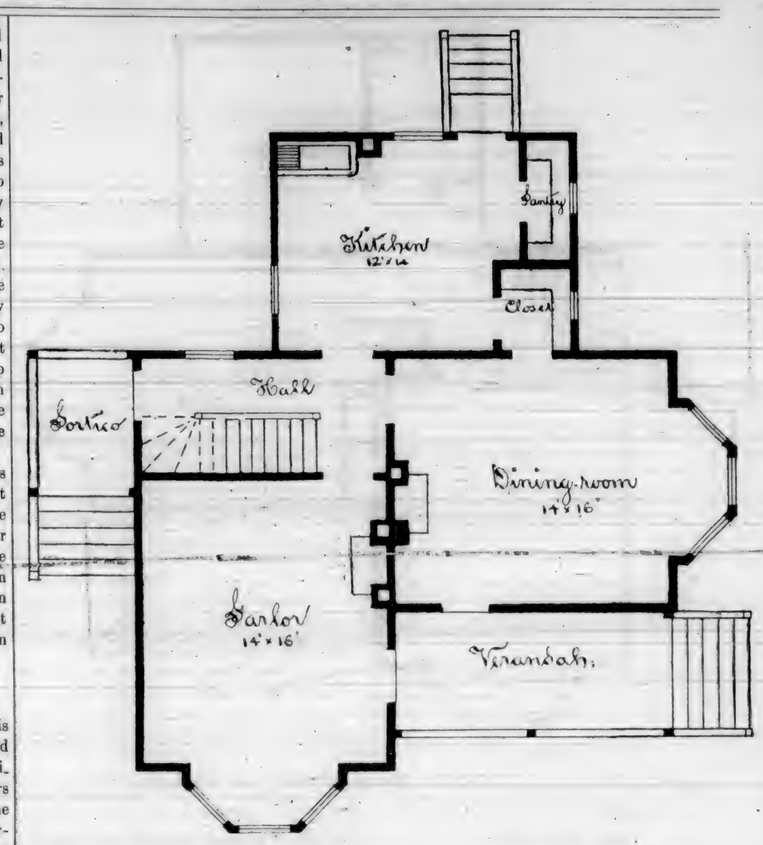

PLATE 5.—PLAN OF FIRST FLOOR, SUBURBAN DWELLING COSTING ABOUT $3,000.

Modern House Painting.

A NEW lot of this celebrated work has been received, which will be forwarded to any address upon receipt of the publisher's price, $5.00.

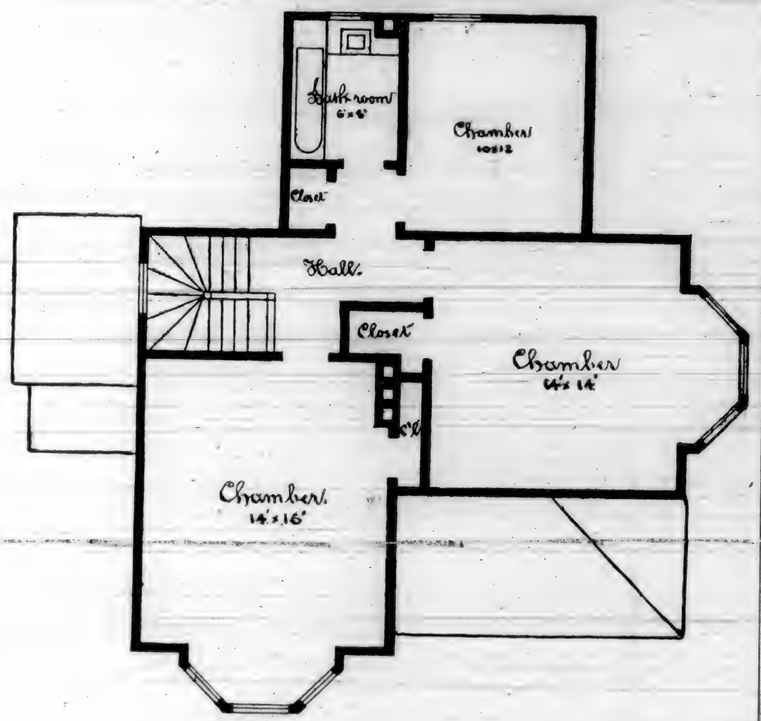

PLATE 6.—PLAN OF SECOND FLOOR, SUBURBAN DWELLING COSTING ABOUT $3,000.

Our Illustrations.

PLATE 1 represents a design for a new building in the latest style of New York Street architecture. It was prepared expressly for this journal and is the second of a series by A. Curtis Bond.

Plates 2 & 3 represent the construction of the dam and reservoir for the new water-works to supply the Pacific Grove, Monterey, and the Hotel del Monte. The engraving marked Plate 2 was prepared by our artist from sketches taken on the ground during the progress of the work, and is very realistic of the scene at the time the view was taken.

Plates 4, 5, 6, are the plans and elevation of a neat suburban residence, the cost of which will be in the neighborhood of $3,000.

SEWAGE PERILS.—Speaking of these, the *Popular Science News* has some very sensible remarks. It says: "The vast number of *traps, valves, automatic plays, bent tubes*, etc., used in houses have resulted from efforts among plumbers and inventors to meet the difficulties of the situation by the first method. It may be said that some degree of success has crowned the efforts of the mechanics to obviate sewage perils, but the success has been by no means what the gravity of the situation demands. At present there does not appear to be a single mechanical appliance known which effectually, under all circumstances, affords immunity from the return of deleterious gases and disease germs into dwellings." But it goes on to say that a Mr. Mallett, a well-known chemist, has invented a device called a *germacide*, "which most admirably meets an important end. This device is very simple, and consists in placing behind the lid of water-closets a black-walnut box, within which is a metallic case holding a mass of crystalline chloride of zinc. This zinc is open to a gentle flow of water, which gradually dissolves it, and it flows into the bowl constantly, night and day, sterilizing the water so that no living germs can pass." This looks very much as if it met and overcame the difficulty.

THE QUEEN ANNE STYLE OVERDONE.—The Queen Anne style of architecture, which soon after it came in vogue here was exaggerated and distorted by builders of cheap houses, is naturally passing out of fashion now that it has been overdone. One of the largest structures now building is in the Italian Renaissance style, and even the architects who introduced the Queen Anne are returning to severer schools.—*N. Y. Sun.*

"FOUNDATIONS." Price, $1.50.

Practical Manuals.

Handrailing and Stair-building. A Complete Set of Lines for Handrails by "Square-cut System," and Full Practical Instructions for making and fixing Geometrical Staircases. By FRANK O CRESWELL, of the Liverpool School of Science, Medallist for Geometry. With upwards of One Hundred Working Drawings. Cloth, $1.50.

Drawing for Carpenters and Joiners. With Elementary Lessons in Freehand and Object Drawing. Containing 250 Illustrations and Drawing Copies. Cloth, $1.75.

Drawing for Bricklayers. With the Elements of Freehand, Object, and Plan Drawing. Containing Two Double and Thirty-two Single Pages of Illustrations adapted for Architectural Drawing Cloth, $1.50.

Drawing for Cabinet-Makers. With Lessons in Ornamental and Object Drawing; Elementary Instruction in Water-Colored Drawing. Containing Twenty-four Single and Five Double-page Plates. Cloth, $1.50.

Drawing for Stonemasons. With Elementary Lessons in Freehand and Object Drawing, and a concise History of Masonry. Containing six Double and Twenty five Single Pages of Illustrations. Cloth, $1.50.

Gothic Stonework. Containing the History and Principles of Church Architecture, and Illustrations of the Characteristic Features of each Period, the Arrangement of Ecclesiastical Edifices, etc. With Seven Double and Eighteen Single-page Plates. Cloth, $1.50.

Building Construction, The Elementary and Architectural Drawing. With 130 Illustrations. 128 pp., cloth, $1.25.

Linear Drawing and Practical Geometry. With about 150 Illustrations, and six Whole-page Diagrams of Working Drawings. 128 pp., cloth, $1.25.

Linear Drawing and Projection. The Two Volumes in One. By E. A. DAVIDSON. Cloth $1.75.

Practical Perspective. With Thirty-six Double-page Illustrations. Cloth, $1.50.

Systematic Drawing and Shading. By CHARLES RYAN. Giving Practical Lessons on Drawing. Cloth, $1.25.

Cutting Tools Worked by Hand and Machine. By R. H. SMITH, Professor of Mechanical Engineering, Sir Joseph Mason's College Birmingham. Price, $1.50.

These are a few of the new series of manuals published by Cassell. They are written in a plain, practical manner, and are profusely illustrated. We will send a copy of either or all of them upon receipt of the price.

Bending Wood.

THE primitive idea of wood bending was to conquer a stick when green and hold it in position, as illustrated in the making of bows. New applications of the underlying principle, and discoveries incident thereto, are constantly being made, and bending for all purposes is readily done by the aid of usually simple appliances and steaming processes.

Where it is desired to have the pieces stay in place, the heart is kept outward, the tendency of wood being to bend outward. But where a corner piece or other difficult stuff is being bent, the heart is kept inside, because admitting of more end pressure or upsetting without giving way or wrinkling. A bent piece increases in weight for its bulk according to the extent it is compressed, being much stiffer, also, than when in its natural and undisturbed state, which makes it especially desirable for carriage work. Tests that have been made with bent and sawed stuff under similar conditions have shown the former to be the stronger. By steaming wood its stiffness is increased, without reference to the bending, and it is also rendered brittle, which is sometimes enough of a characteristic to be detrimental to its quality. One kind of hickory is better for spokes or whiffletrees after it has been steamed, while another kind becomes very stiff when air-dried. Kiln-drying and steaming both cook the gum in resinous woods, and hence have a similar effect. Stiffness is the desirable quality in a spoke, felloe or whiffletree, and in hickory it is always increased by steaming. It is difficult to splinter or tear a piece of bent wood. Its fibres have become interwoven, and, without being particularly indicated on the outside, the interior becomes materially changed.

The steaming is usually done in boxes. Two or three hours is enough steaming for many ordinary purposes. Corner pieces require a whole day, and timber that is hard and tough should be steamed from 24 to 36 hours. For light panels 10 or 15 minute's steaming is sufficient, and most hard woods need only a half hour. A nice discrimination as to time is highly essential to success. By over-cooking timber the virtue can be made to depart from the toughest wood, rendering it punky and without elasticity. Live steam is not indispensable, exhaust steam being frequently used to advantage. Neither is a great quantity of steam required, partially condensed or damp steam being considered the best. A tight box with enough steam fed into it to make the wood sweltter and cook is sufficient. After being bent the twisted fibre sticks as stubbornly to its new course as it did to the directions of nature. Bending is chiefly done on wheels and forms. A strap is used in numerous cases, and is indispensable in such bending as shafting, to keep the wood from slivering.—*Northwestern Lumberman.*

Incombustible Paints.

WATER-GLASS is being extensively used in the production of a paint which in addition to its durability is also a protection against fire, and as a floor paint it is especially recommended.

The surface of the floor having been well cleaned, any crevices or cracks between the boards are next luted with a thick mixture of water-glass and pulverized chalk or gypsum; then, by means of a stiff brush, a coating of water-glass, of sirup like consistency, is spread over the floor, and to this succeeds a second coating of the same, mixed with the desired color—the latter a mineral color, as the alkalies of the water-glass commonly decompose vegetable colors. This coating having become dry, other layers of the water-glass are given until the floor acquires a fine lustrous appearance. In order to insure a polished brightness, the surface is ground off a little, oiled, and thoroughly dried. A number of patents have been granted for incombustible paints in this country, and among the foreigners who have experimented with different ingredients for accomplishing this end, MM. Vilde and Schambeck propose the following mixture for rendering wood-work incombustible:—

Pulverized glass	20
Pulverized porcelain	20
Pulverized stone	20
Calcined lime	10
Silicate of soda	30
	100

The solid elements must be reduced to as fine a state as possible and sifted, and then mixed intimately with the soluble glass, thus forming a glutinous mass which may be employed as it is for painting, or may be mixed with various colors.

The addition of the lime gives a certain unctuosity to the mass for painting, while the combining of this lime with a portion of the silicic acid of the soluble glass promotes the intimate mixture of the other substances.

Although the mixture given above is recommended as being the best, the proportions of the various elements may be changed according to circumstances, except that of the soluble glass, which must remain constant. Some of the substances may also be replaced by others; but it is advisable to retain the lime. Instead of silicate of soda, the soluble glass of potash may be employed, but the former is cheaper,

The paint is laid on with a brush, in the ordinary manner and as evenly as possible, on the surface to be protected. The first coat sets immediately, and the second may be applied from six to twelve hours afterward—two coats being sufficient. This composition may also be employed with advantage for protecting iron bridges, sleepers, etc., from oxidation.—*Scientific American.*

Australian Trees.

THE giant trees of California, which have been one of the wonders of the world ever since their discovery, some twenty-five or thirty years ago, are now found to be far surpassed by certain specimens of the eucalyptus found in the mountains of southeastern Australia. The highest tree at present standing in the groves of Mariposa County is three hundred and twenty-five feet high, and this is only the largest out of a small number of specimens of a tree found nowhere else, while the Australian forests contain many thousands of greater height than this, one of them, the tallest yet measured, being four hundred and seventy-one feet from the ground to the summit. The diameter at the base of this enormous plant is eighty-one feet, so that, if it should ever be cut down, a squadron of cavalry might go through its evolutions on the stump, in place of the modest quadrille which it has given so much pleasure to the Californians to dance upon the truncated fragment of one of their great sequoias. As in California, the largest of the Australian trees are no longer standing, and a prostrate trunk has been found which measured four hundred and thirty-five feet from the roots to the place where the upper portion had been broken off by the fall. The broken tip had disappeared, but as the diameter of the trunk at the point of fracture was three feet, it is estimated, with great probability, that this indicates an additional length, for the perfect tree, of at least seventy feet, making the whole height of the plant more than five hundred feet. Concerning the time required for developing from a very minute seed a tree which would overlook the Great Pyramid, no inquiry has been made, and as the evidence of the so-called annual rings is now known to be worthless for determining this point, we may never be able to form even an approximate estimate of the age of these giants, but the common eucalyptus has been observed to grow from seed to a height of sixty feet in ten years, and it is quite probable that a few centuries have sufficed to bring specimens planted in a favorable soil to their full development.—*American Architect and Building News.*

HAND SAWS

How to Select and How to File Them.

PRICE $1.00.

This work is intended more particularly for operative Carpenters, Joiners, Cabinet Makers, Carriage Builders, and wood-workers generally, amateurs or professionals.

It is a complete guide for Selecting, Using, and Filing all kinds of Hand Saws, Back Saws, Compass and Key Hole Saws, Hack and Butcher Saws; showing the Shapes, Forms, Angles, Pitches, and Sizes of saw Teeth suitable for all kinds of saws, and for all kinds of Wood, Bone, Ivory, and Metal; together with Hints and Suggestions on the choice of Files, Saw Sets, Filing Clamps, and other Matters pertaining to the Care and Management of all Classes of Hand and other Small Saws.

Illustrated by over Seventy-Five engravings. This work is edited by the author of the "Steel Square and its Uses," "Builder's Guide and Estimator's Price Book," "Practical Carpentry" etc. Being sole agents on the Pacific Coast for all the above mentioned works, we are prepared to furnish dealers and agents at publisher's prices. Single copies sent post-paid upon receipt of price.

Book Notices.

LIFE OF SIR WILLIAM E. LOGAN, K. T., LL.D., F. R. S., F. G. S. First Director of the Geological Survey of Canada. By BERNARD J. HARRINGTON, B. A., Ph. D. With steel portrait and numerous woodcuts. New York: John Wiley & Sons, 15 Astor Place. 1883. Price $2. 50. 432 pages, octavo.

The principle work of Sir William Logan's life was the Geological Survey of Canada. His ability, energy, and genial qualities gained for him the esteem and affection of many of the best and most eminent men of science. Canadians especially cannot afford to forget the name of one who labored so long and so earnestly to promote the interests of their country, but others too will be grateful to the author for the compilation, which sets forth the admirable character and work of the greatest geologist. The style of the book is excellent, the account is entertaining and pleasant reading throughout, and the make-up is all that could be desired. Most of the illustrations scattered throughout the volume are copies of pen-and-ink sketches from the note-books of Sir William Logan.

THE MATERIALS OF ENGINEERING, by R. H. THURSTON, A. M., C. E., published by Wiley & Sons, New York.

This standard work is issued in three parts. Part one has already been noticed. Part two, IRON AND STEEL, has just been received. The chapters on the properties of iron and steel, and the strength of the same, are the most comprehensive to be found in any work that has, as yet, been brought to our notice. The result of the numerous tests in regard to the strength of each metal, are given in a tabulated form, and will be found much more interesting than other works of a similar character. It is beautifully illustrated, and contains 675 pages. Price of Part two, $5.00.

Stairs.

THERE are a few people who do not "mind" running up and down two or three flights of stairs several times a day. They "get used to it" they say, but to the majority of people stairs are a positive labor and weariness without any sufficient compensation. If one could enter a fifth-story room with the same ease as he can enter the first and second story rooms, the most of us, other things being equal, would prefer a room of that altitude. The air is purer, the quiet deeper, and interruptions less frequent. In hotels and other large buildings, where there are elevators, there is comparatively slight difference in the charge for rooms of the same grade on different floors and with reason—a minute more or less in reaching one's room does not count. A flat in the upper floor of a four or five story building, containing an elevator, is often rented when the other floors are vacant, not only on account of its moderate price, but because it is high and quiet and isolated.

Of late years the minds of inventors have been turned toward the invention of an elevator which could be moved by some other power than steam, and patents have been applied for, but such has been the depression of all trade, and especially of the building interests, that there has been little encouragement for efforts in this direction. But it is certainly to be greatly desired that some cheap and facile method be devised for bringing all floors substantially to a common level, and abolishing the fatigue of climbing stairs and the evils that flow from it. This is very desirable in schools and colleges for women. There are more girls and young women disabled for life by climbing stairs while they are going to school than by any hard study they are guilty of. If their clothing was suspended from the shoulders, and not from the waist, the evil would be lessened, but even in that case it would not cease to be formidable. In many schools and colleges for girls, the pupils regularly several times a day, go up and down three or four flights of stairs to their rooms, up and down as many more to attendance in the laboratory, the art gallery, and the recitation rooms, until they are as much, if not more, exhausted by this labor as by all their other toils put together. There is certainly no objection to elevators in male colleges, but there is every reason why they should be in institutions for the other sex.

In our private houses the aim should be to have the work of the family as far as possible on one floor, and to abolish every step up and down that can in any way be dispensed with. Cellar kitchens are a nuisance and an abomination to be tolerated only in case of dire necessity. Sub-basements are a convenience if dining-room and kitchen can be on the same floor, and in our cities, where land is bought by the foot and the inch, they are a necessity. But in the country, where land is cheap, there is no economy in piling story upon story, and enforcing the continual running over flights of stairs by house-keepers and servants in their performance of the household. A great deal of labor can be saved, and is saved, by having our houses heated by steam, and by having water in and out on every floor; but these are luxuries not within the reach of the masses of country people, who can, however, because land is less valuable in the country than the city, so build as to dispense with them with slight inconvenience.—*The Builder and Wood-worker.*

A Main Chance.

THERE never was a time more opportune than the present for the general introduction of yellow pine lumber. The dealers who desire to push its sales have a splendid opportunity to do so. A doubt regarding the value of such lumber for building purposes does not find a place in the mind of any man who understands its durability, and the difference in cost between it and white pine. It is evident, however, that there is something in the way of its general use. When the two kinds of pine come in competition, nothing is more rational than to suppose that the public would buy the cheaper, providing it will answer every purpose of the dearer. The average man has an inherent desire to buy as cheaply as possible. One objection against the general use of yellow pine arises from the builder. He is not, voluntarily, going to make a contract for working a certain kind of wood, when he can handle another with more ease. This applies more particularly to inside finishing. For bridge timber, building dimension, and other grades which are not necessary to be worked to a smooth surface, he is less particular. White pine is easily sawed and planed, and the carpenter courts the ease with which it is done. For the same reason, somewhat intensified, the wood-worker gives hemlock a wide birth. He has no affinity for its slivers. He has a kind and natural regard for his hands and tools, and he is not willing to overcome this regard for the sake of cheapening a building a few dollars.

There has been a current belief in the Northern States that yellow pine will not hold paint satisfactorily. It has been thought that any exudation of pitch would stain the paint, and to a certain extent force it off. This idea, however, has been greatly magnified. In sections of the Southern States, where little besides yellow pine is used for building purposes, there is usually heard but little complaint. Occasionally, a builder will put a coat of alcohol over the outside work, which cuts any pitch there may be on the surface, but oftener no special process is employed.

There is still another objection to yellow pine for inside work, finished in the natural color, that has sometimes arisen, that is simply the result of taste. To the eyes of some the effect is too glaring. The ones who take this exception assert that they tire of it more quickly than of a more somber-colored wood. The color is too vivid. The effect at first sight is cheering, but it is short-lived. As we remarked, this is simply a matter of taste, and one that every man should decide for himself. Yellow pine does not stand alone in this respect, for exceptions are taken to the color of other woods. Walnut, for some, is too dark, and for others cherry is too red. If the brightness of yellow pine is a serious objection, it is one that time in part overcomes, for it will grow dark with age.

The opportunity that the yellow pine handlers have of pushing their lumber, arises from the feeling that exists between the yard dealers in white pine, and the manufacturers of it. The former are crying for cheaper lumber, and the latter are strenuously endeavoring to sustain prices. If there is a cheaper lumber than white pine that can now step in and satisfy the minds of the dealers as to price and satisfy them otherwise, its advent would be hailed with shouts.—*Northwestern Lumberman.*

"Not only unequalled, but unapproached. A literary enterprise more deserving of a generous sympathy and support has never been undertaken on this side of the Atlantic"

The Works of Hubert Howe Bancroft.

IN 39 VOLUMES, OCTAVO, WITH MAPS AND ILLUSTRATIONS.

Vols. I–V.—The Native Races of the Pacific States.
Vols. VI–VIII.—History of Central America.
Vols. IX–XIV.—History of Mexico.
Vols. XV, XVI.—History of the North Mexican States.
Vol. XVII.—History of New Mexico and Arizona.
Vols. XVIII–XXIV.—History of California.
Vol. XXV.—History of Nevada.
Vol. XXVI.—History of Utah.
Vols. XXVII, XXVIII.—History of the Northwest Coast.
Vols. XXIX, XXX.—History of Oregon.
Vol. XXXI.—History of Washington, Idaho, and Montana.
Vol. XXXII.—History of British Columbia.
Vol. XXXIII.—History of Alaska.
Vol. XXXIV.—California Pastoral.
Vol. XXXV.—California Inter Pocula.
Vols. XXXVI, XXXVII.—Popular Tribunals.
Vol. XXXVIII.—Essays and Miscellany.
Vol. XXXIX.—Literary and Industries.

THE HISTORY OF THE PACIFIC STATES is the central figure of this literary undertaking, the *Native Races* being preliminary, and the works following the History supplementary thereto. The territory covered is the western half of North America, from Panama to Alaska, including all of Central America and Mexico, and is equivalent in area to one-twelfth of the earth's surface.

CONDITIONS.—The volumes will be well printed, on good paper, and neatly and substantially bound; they will be uniform in style, and will average over 700 pages each. Three or four new volumes per annum will appear until the entire series is completed. Subscribers will not be obliged to take the work unless it corresponds with the description in every particular.

	PER VOLUME.
Bound in Extra English Cloth, neat and attractive style	$4 50
Bound in Fine Leather, Library Style	5 50
Bound in half Calf, Half Russia, or half Morocco	8 00
Bound in Russia Leather or Tree Calf	10 00

Any information in regard to the above will be given, by addressing the office of this journal.

Our Prosperity.

WE return hearty thanks to one and all for the very many extremely flattering and favorable notices. Commendations and congratulations received—personal and editorial—in reference to the handsome improvements in the appearance, and in the illustrations and matter contained—more especially in the recent number of this journal. Without detraction from previous issues, its June number placed it upon equal footing with the best and most meritorious class journals published in the English language; and it has been so recognized. And while its managers have great reasons to feel proud of the success achieved, the people of the entire Pacific Coast—particularly those of San Francisco—have also reasonable ground for pleasure at seeing produced and established, without peradventure or question of failure, a publication in the building interests, alike creditable to its proprietors and the city in which it is issued.

But it should not be forgotten that the results obtained have been reached only by indomitable effort and perseverance, for in its infancy even those who wished it well feared and doubted its success. Kind expressions were not wanting, but the doleful accents of doubt were often coupled with the wish that it might succeed; and for a time its demise was a matter of monthly anticipation by many. But, as stated in its early numbers, when discouraging shadows hung about us, we entered not blindly into the undertaking, but had counted the cost and measured the strength of our arms, and to-day we enjoy the proud satisfaction of having risen above all contingencies, admired and approved by thousands, and the words of approval which now come to us from all quarters, have the clear ring of well-wishing and unqualified confidence.

But, however gratifying and appreciable kind words may be, they are not available in the payment of the necessary cost and expense of publication, nor negotiable with grocers, butchers, bakers, clothiers and others who furnish the food and raiment, eaten and worn by those who perform the labors incident to the production of this journal monthly. Consequently, while our list of subscribers is daily increasing with pleasing rapidity, there is room for greater, and we urge our claim to universal support upon all classes of citizens, as not only those who plan and build, but those who own their residences, and those who occupy rented houses, are alike interested in the matter and subjects contained in its columns; and none should refuse or fail to lend the helping hand. San Francisco alone should give us ten thousand paying subscribers.

How Spools Are Made.

BEARING in mind an inquiry made of us some time since, we present the following interesting description of the *modus operandi* of making spools, as carried on in the extensive factory of the Searsport Spool and Block Manufacturing Company, in Searsport Village, Maine: This company own large tracts of land in northern Maine, from which the lumber for spool-making is cut, white birch being used exclusively. The wood is first sawed into pieces four feet in length, and of nine sizes, varying by sixteenths, from an inch to an inch and a half square. It is then dried as thoroughly as it can be out of doors. Inside the factory it first goes to the "rougher," where the strips are cut into cylinders of the length of a spool, and the hole bored, the turning and boring being performed at one operation, and the cutting off, with a small circular saw, at another, all on one machine. These little cylinders drop from the rougher into a barrel, from whence they are removed to the "rollers," or revolving slatted cylinders, in which the fine dirt and fuzz left by the saw and bits are removed. The pieces are then picked over by hand and all imperfect ones are sorted out to feed the ever hungry fires under the boiler.

The next process is a more thorough seasoning of the blocks in a loft, and then they go to the "reamer," where the center holes are made to the exact size required, which cannot be done by the rougher on account of the shrinking of the wood after leaving that machine. Until lately the reaming has been done by an ordinary reaming tool working in a lathe, the work being fed by hand, but a new machine has been recently put in, which will ream the spools as fast as two boys can feed them into the spouts. This reamer was made by the company's machinist, Mr. John F. Rogers, at the machine shop in the factory, from patterns made by him, he having seen a similar machine working in McGregor's factory in Lincoln, Me. The machine in use in the Searsport shop has some features which the builders claim are improvements over the original, which was imported from Scotland, it having lately been invented in that country and not yet patented in the United States. It consists of a short revolving shaft, with a reaming tool at each end, working endwise backward and forward about four inches. At each end spouts are arranged with feeding apparatus which forces the spools into the proper position to be bored, and then allows them to be dropped out into a barrel below. At each oscillation of the shaft two spools are reamed, one at each end, the machine turning out about 240 per minute.

The next machine is the "finisher," which is an attachment to an ordinary lathe, by which the spools are turned into shape at one operation, at the rate of from 1,000 to 1,500 per hour. There are eight cutting knives on this machine; one at each end, standing up perpendicular to the length of the spool, for trimming the end; one at each end, horizontally, for turning the outside of the flange; between these, two others, standing diagonally, for the inside of the flange; another, horizontally, for turning out the space between the two flanges; and a small circular chisel for cutting the finish on the top of the spool. The spools have now received their shape, and need only the finishing touches. These are given, first by the "polishers," which are the same as the rollers described above, the friction of the spools against each other giving them the required polish. After remaining in this from four to five hours, they are again sorted by hand, and all imperfect ones removed, after which they go to the "embosser," a sort of printing machine, which stamps the number of the thread and some ornamental devices upon the head of each spool. They are then packed in stout sacks, holding from thirteen to thirty-six gross each, according to the size of the spools.—*The Manufacturer and Builder.*

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, per square, each insertion	$ 2 50
Back " " " "	2 00
Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each Subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is ¼ of an inch in length by width of the column. When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

Bound Volumes of this Journal.

Bound volumes of 1879, 1880, 1881, and 1882 (in one book) complete, with all ads. and covers removed, will be sent to any address upon receipt of $8.00.

Bound volumes 1881 and 1882, each $2.50
" " 1880 (only a few left) $2.00

In 1880 the subscription price of this journal was only $1.50, and we have put the price of bound volumes accordingly.

Volumes of 1882 and those containing all the numbers from the first issue, bound in one volume, are supplied with a full index.

Any one failing to receive a complete index will be supplied by sending a postal card to this office with their address.

All Impediments to Building Improvements Removed.

THERE has hitherto—since 1880—been two matters of law which have discouraged many owners from improving their property by the erection of buildings: *First*, the Mechanics' Lien Law, as it appears on the statute book, and during the past three years generally accepted as the law governing the matter, made owners liable for all bills contracted in the erection of buildings, for labor, materials, etc., without regard to the sum of contract. This feature has been set aside by the recent decision of the Supreme Court, as elsewhere stated in this issue, and the declaration made by the court of last resort, that owners can be holden *only for the amount expressed in the contract*. Consequently the lien law is now as it should be, harmless against owners, beyond the sum of contract. *Second*, the ruling of the Supreme Court in the case of Zeile *vs.* Hood, as elsewhere herein stated, supported the doctrine that owners excavating for the purposes of building were obliged to sustain and underpin structures on the adjoining premises. The effect of this ruling was to discourage many from making improvements, they preferring to allow their property to remain unimproved rather than be forced to bear the expense of sustaining their neighbors' buildings. But the Supreme Court has, by a late decision, removed this obstacle, by virtually affirming that every owner of real estate shall have the right to excavate to the depth of fourteen feet below the curb level, with the simple restriction that proper written notice of intention to excavate shall be served upon adjoining property owners, who must, upon the service of such notice, take care of and underpin such buildings, etc., as may be affected by such excavations, at their own cost and expense.

Mechanics' Lien Law.

DECISION BY THE SUPREME COURT.

THE Supreme Court of this State, in a decision rendered in the case of Latson *vs.* Nelson, filed July 24, 1883, has defined and fixed the legal force and effect of the Mechanics' Lien Law of California, thereby setting at rest all questions as to the rights of owners, contractors, material men, and others, whose interests may in any manner, now or hereafter, be affected by the operation of the law.

The construction placed upon the Lien Law by the court of last resort fixes the fact that owners of real estate and others entering into contract obligations are bound by the conditions and agreements, and for the specific sum expressed in the contract entered into, but not for any sum greater than the contract amount, all other things being regular. The Legislature convened next following the adoption of the new Constitution, amended the Lien Law passed April 11, 1872, by striking out the illogical and absurd section which had been adopted with the passage of the law as a whole, which made all parties—architects, mechanics, material men, artisans, and even common laborers—performing labor, rendering services, or furnishing material for or in connection with the erection of buildings, etc., at the instance and request of the contractor, without the owner's assent or approval, "*the agent of the owner for the purposes of this act.*" A proposition so adverse to all principles of law and common rights, was, as a matter of course, doomed to repudiation whenever submitted to the judgment of an impartial, competent tribunal. Consequently, when the law of 1872 was appealed to the Supreme Court, the—everybody—an agent of the owner feature, was virtually stricken from the statute, leaving the rightful protection which the law provided, of liens against property and improvements for the full amount of contract and no more.

In place of the section stricken out, however, another was substituted by the Legislature of 1880, of similar import and character, and equally as inequitable, being no more nor less *in effect* than a re-enactment of the rejected section in a new wording, the material clause of the new section (1) reading as follows: "*This lien shall not be affected by the fact that no money is due or to become due on any contract made by the owner with any other party.*" Thus placing owners at the mercy of those to whom they might intrust their interests by contract, without any security whatever in or under the written agreements. True, owners by requiring bonds and securities *outside* of the contract—by drawing in and involving innocent parties as bondsmen—might, at the end of a lawsuit, save themselves by recovery upon the bond, less the costs, vexations, and annoyances ever attending suits at law. Upon this point the Supreme Court, in its late decision, remarks: "*It is said that the owner has full security in the right to require a bond of the contractor that no liens shall be created. So far as that is any argument, it may with equal force be said that the material man may require payment or security of the contractor before parting with his goods!*"

But while this decision settles the Lien Law question and places the responsibilities and securities just where they should rest, there are some who will insist that the Supreme Court has erred in its judgment and should be reversed.

As a matter of course, those whose interests are secured and protected by the decision will approve; while those who have hitherto felt themselves safe against the defaults of contractors, by enforcing their claims against owners without regard to contract considerations, will disapprove. This is a natural sequence, as the justice and equities of all laws, as a rule, are weighed and valued by individuals in the light of personal interests; consequently there will ever be uncertain diversities of opinion; for the law approved and advocated under one set of circumstances, will, by the same parties, be rejected and opposed at other times, because of reversal of issues. Every good man claims to be a law-abiding citizen, and is so in fact when there is no sacrifice required in occupying that position; but when law and individual interest come in conflict, no man living will yield personal interests to law, if by any means it is possible to secure those interests, even though all the laws upon the statute books of the land should be sacrificed.

This, however, is certain for the present: The Supreme Court has, by its late decision, ended all speculation and controversy in reference to the Lien Law, and those who desire to make improvements can do so without fear of being called upon to pay more than the contract price.

Epidemics—Sewerage South of Market Street.

We clip the following from the *Examiner:*

"Health officer Mears is of opinion that there are no grounds for fearing an immediate introduction of cholera, yellow fever, or small-pox into San Francisco, but thinks that the city should be placed in proper sanitary condition, especially as regards the sewerage south of Market Street."

All of which may be true. We have repeatedly referred to the condition of the sewerage south of Market Street, and urged the necessity of its improvement, not only as a safeguard against epidemics, but for the general health of the people residing and doing business south of Mission Street. But how is this to be done, with the general grade of the streets as they are, taking the line of Sixth Street as a guide, with the last five blocks in from the outlets of the sewer as base, a total distance of over 2,000 feet, without any fall whatever, the established grades being: Mission Street, thirty feet; Howard Street, ten feet; Folsom Street, five feet; Harrison Street, two feet, and Bryant, Brannan, Townsend, King, Berry, and Channel Streets at zero, the greater number of the blocks being 550 feet, beside the width of crossing streets. The only apparent remedy under the circumstances is the filling in and raising of the whole district so affected to a uniform grade from the higher point—Mission Street—and making a uniform grade of thirty feet from Mission Street to the mouth of the sewers, instead of twenty feet from Mission to Howard, five feet from Howard to Folsom, three feet from Folsom to Harrison, two feet from Harrison to Bryant, and a dead level of 2.000 feet and over from Bryant to the sewer outlet, the other corresponding streets being at the same disadvantage. To do this will now cost a considerable sum of money, which, however, would be more than compensated by the increased value of the property affected, as it is a certain thing that the property of the entire section would double in value were the filling-in done. At present, and for years past, a cloud has rested upon the whole district mentioned, and it has been in continued disfavor, owing to the state of facts recited. There is no good reason why the property south of Mission Street should not be very much more desirable than it is, the only drawback being its flatness and want of good sewerage, and consequent dampness generally; all of which can be remedied, and would have been twenty years ago had the order then passed by the city council been carried out, which order placed the grade of Folsom Street, at Sixth, seven feet higher than its present depression. But the importance and necessities for this change of grade was not so forcibly apparent then, although the cost at that time would not have been more than one-tenth what it would be at present, and the property owners in that section, failing to anticipate present conditions, they succeeded in nullifying the order, and property south of Market Street has been injured millions of dollars in depression of values and income.

If this filling-in was determined upon and put into practical execution now, even at its greater cost—owing to the number of buildings that would have to be raised, etc.—it would pay, as it would require the hills and banks of materials now occupying numerous valuable lots and whole blocks in various parts of the city, which remain from year to year ungraded because of the cost involved, grading being expensive work, owing to the great lack of convenient dumps. There is no other one project that would be more beneficial to the city of San Francisco than that suggested in this connection, as it would give employment to thousands of men and hundreds of teams, and add millions to the assessable value of property, both south of Market and that which would be increased in value by being graded off to furnish the filling-in material. Sacramento furnishes an example in the filling-in of the entire city ten feet more or less, by which the healthfulness and importance of the city was greatly improved; and there is no good reason why that part of San Francisco which might be made very desirable for both business and residence purposes should be held at its present low standard, owing to its shamefully insufficient sewerage. and the lack of enterprise on the part of those most interested to reclaim it, and make it what it is capable of being made.

Mr. Theo. A. Eisen has resumed the active practice of his profession as architect, and can be found at 218 Post Street, San Francisco.

Old Homes Made New. Price $1.50.

Sensible Letter from a Lumber Dealer.

Editor California Architect — *Dear Sir:* Much has been said from time to time by interested parties in reference to the "Mechanics' Lien Law," as to the protection it affords citizens and material men. A good deal of law and legislation has been had to try and make it what it was and is intended it should be, to wit, absolute protection. But all the brains, time, trouble, and expense heretofore bestowed upon it seems, under the late decision of the supreme authority of the State, to have gone for naught; and now, practically, the "lien law" is in the same condition it was before the adoption of the new constitution, which was at best a "trap and a snare," except as between principals. Now I think a great deal of trouble, anxiety, and not a little coin can be saved if the parties who first contribute to the "start" of a building, to wit, the lumber dealers, of which I am one, would refuse absolutely to furnish lumber to any party who they would not consider worthy of credit, independent of a possible security through the "lien law." This would have the effect of shutting off all those who now, and for many years have disgraced an honorable calling, the "contractor and builder," and reduce the number of "figurers" to those who have a respectable standing in the community and whose credit is beyond question, thus enabling them to obtain a fair price for their work, leaving them a legitimate profit, and in turn to pay a fair price to all those who in any way contribute material, brain, or muscle to the structure. In this way owners would get better work and better value for their money, because all sub-contractors would, without doubt, work with a better grace and feeling and at a lower price, knowing that their pay was absolutely safe, and removing that uncertainty that at present, to a great extent, exists; and I claim also that owners would reap many other benefits that I may point out at some future time. How many owners are there who heretofore have had to defend their property as against "liens," through no fault of their own, but through the incompetency if not the dishonesty and unreliability of their builder. And how many architects have been annoyed beyond description from the same cause. Hence I repeat that the whole fault lies with the lumber dealer; for if the contractor, or the party who sets himself up as such, could not get lumber he could not "start" his job, and would be forced to withdraw in favor of some more responsible person.

In my opinion all artisans and material men would be better off if there was no "li n law" at all, except as between principals, for, as I have hereinbefore stated, the present "lien law" is nothing more or less than a "trap and a snare" to catch unsuspecting victims.

Not desiring to impose upon your good nature by taking up too much of your valuable space in presenting my humble views, I will close. Yours respectfully,

A Lumber Dealer.

New York Street Architecture.

A. CURTIS BOND.

THE ROMANESQUE.

The Romanesque, corrupted from the Roman, has invaded all other styles and left them marked with its name and its peculiarities; those familiar to us to-day, the Byzantine, the Moresque, the Gothic, have all appropriated its suggestions and its patterns, until we have almost sunken the individuality of the Romanesque proper and transformed the title into an adjective descriptive of a place of the orders named.

In the early Christian styles the tendency of the Romanesque influence was toward creating tall towers, square capped and without any appreciable variation in measurement at the extreme top or bottom; in columns the greatest latitude was permitted, for not only were they frequently unlike in proportions, but the material and workmanship presented contrasts that cannot be said to have always been either picturesque or harmonious. The disposition was to have all things one-sided, unequal, illy-balanced, towering to an awkward height and then ending abruptly in a flat-looking cap.

In another instance of the Christianized Romanesque the form of the bath was adopted, a circular structure with a center dome, all of the building being embraced within the limits of the circular walls, no wings nor other projections being usual.

With the progress of events and the advance of architectural skill, the Byzantine came into existence and the Romanesque took another form as it entered into this new acquisition to the orders. The prominent features of this new form of buildings were heavy piers and spreading arches supporting a dome that rose over the center and had vaulted side spaces connecting with it. Columns were used more as ornamental and decorative features than as entering into the necessities of construction; cornices and capitals were discouraged, and in many instances they were almost entirely ignored. The church of St. Sophia at Constantinople is generally selected as being the most brilliant and authentic example of this style. It is certainly one of the most wonderful in point of extent and elaboration that has ever been constructed. It rises gradually from comparatively low arch-supported side structures, to the rotund roof of an inner row of vaults, and from these latter swells gracefully and magnificently into a dome that is nearly 200 feet above the pavement, and looks down upon an interior decoration and display of niches that made it, even in those extravagant times, an object of admiration and brilliant example for other humble but ambitious designs.

As the Byzantine made itself known and spread through Europe, its Romanesque ingredient became more and more evident, and in Armenia, for example, the Byzantine character was preserved only in the ornamentation; the shape, lines, peaked roof and towers, surmounted by a shapely slanting cap, were eminently Romanesque, uninfluenced by any other styles.

In Russia, on the other hand, there was made up such a conglomerate specie of architecture that almost every possible style was made a part, sharp roofs, pinnacle-like in their height and slender proportions, their outlines jagged with protruding ornaments and the apex crowned by a small ball. Towers rose in the same building, octagonal and having balconies at irregular intervals, and supporting an immense globe, shaped like a gigantic inverted bubble, with the stem pointing toward the sky and adorned with numberless chains and gilt ornaments that sparkle and glisten to the intense delight of the superstitious crowds thronging the plaza below, and who, between the shouts of long life for their Pope and father, the Czar, paid their devotions to the painting of their saints, protected beneath these hybrid roofs and pictured by the local artists in high-top boots and attired in the costumes that we can only associate with modern civilization. The domes are painted in brilliant colors, silvered, gilded, yellow, red, or white, green or blue, with bright stars sprinkled over all, and the colors laid on in stripes, squares, circles, as the architect felt was the more effective. Such an architecture as this, while it is unquestionably unique and peculiar, lacks the tasteful attrac-

Plate 1.—Dry Dock Savings Bank.

tions of other forms of the Romanesque, and becomes almost absurd in its mass of detail and useless accessories.

From the Byzantine to the Mahometan is but a step, but the difference is noticeable. We leave a style marked by fanaticism, an ornamentation burdened by symbols, lavish in its extent and religious in its character, oppressive with its reminiscences of assumed martyrdom, or with its monograms and trade marks of saintly individuals; and yet, withal, a style that is original and becomes with closer study interesting.

The Mahometan, on the contrary, aside from its occasional introduction of passages from the Koran—the letters of the language combining so well with the ornamentation as to appear as a part of it—with this exception, there was nothing to remind one of what is considered by many the serious affairs of life, and everything to create in the brain a lively imagination and an exaggerated sense of enjoyment.

The Mahometan Romanesque in Spain became the Moresque, whose gradual filiation through the requirements of the different countries to the restriction of street architecture in this city we showed the result of in our June number. In Turkey it displays a barren wall pierced by small windows, prompted

to this cloister-like aspect by jealous pashas and exuberant *odalisques;* in Egypt variety is given to the outward appearance by latticed bow windows clinging to the house side, and at which an occasional glimpse is had of a peeping face partly concealed by a veil, the female herself being rigidly guarded from the sight of the Caucasian race, though why it is difficult to understand, for the few samples of this particular kind of household appurtenances that I saw, in a recent visit to that country, had very few charms of features, and their corpulency was of that pronounced type vulgarly associated by us with those Cuicuinations recently ruled out of Germany by Bismarck. In Spain the forbidding exterior was replaced by one of great beauty.

It is perhaps unnecessary to follow the thread of the Romanesque through the various stages of its modern development. It would be an interesting study, though a lengthy one, and we may some day return to the subject with illustrations of the prominent peculiarities of each stage. It has found its way into Germany, Italy, France, and England; there is a Venetian Romanesque, an Italian, French, and Spanish, with minor branches such as the Provencal, Angiovine, Aquitanian, the Apulian, and the Pisan. The Oriental spirit is inherent in the Apulian form, and it is rich in sculptured animal figures; a Gothic tendency is found in French and Spanish.

By the time it reaches our country it becomes what we see it in our accompanying illustrations. Figure 1 is a representation of the Dry Dock Savings Bank and is as near an

PLATE 2.—DWELLING IN AMERICAN ROMANESQUE STYLE OF ARCHITECTURE.

approach to the true Romanesque as modern New York architects will tolerate. The building is of light stone with tile caps over the windows and doors; the entrance is richly sculptured, and the Gothic balcony has its roof supported by polished marble pillars. The sloping roofs are slate. The style is what is strictly known as the English Romanesque, the arches and balconies tending toward the German Byzantine; an application of the form very far from its original purpose

Figure 2 is a more modernized American Romanesque of really good lines and embracing English Gothic windows with Byzantine details. The building is of brick with light stone trimmings and gray slate roof. It stands at the corner of Fifty-seventh Street and Fifth Avenue, and is the residence of Mr. F. W. Stevens The exterior is so inviting in appearance that we have intruded upon the privacy that should protect one's home and reproduce from our New York contemporary, *The Decorator and Furnisher*, an excellent view of the parlor, in which the ceilings are heavily paneled and the walls are hung with tapestry. The mantel is a wonderful combination of embossed velvet, and the columns rising from it are of highly polished wood. With our reader's permission I will digress for a moment to show them the dining-room of this house, and my only excuse must be that it is one of the most noticeable and written about of any similar room in the city. The walls are decorated in Pompeian red and portieres of Japanese silks are suspended at the doors; stained glass windows representing the

PLATE 3.—INTERIOR VIEW OF THE PARLOR IN AMERICAN ROMÁNESQUE DWELLING.

(From the New York Correspondent of the CALIFORNIA ARCHITECT AND BUILDING NEWS.)

seasons, and others bearing the ever-hungry goddesses, Pomona and Ceres, are six in number; mottoes suggestive of the pleasures of the table are upon the walls, and they are so arranged as to enter into the ornamental figures and form a part of them. Light is provided at night by means of candles, thus avoiding the destructive qualities of gas. I might lengthen this brief description, but feeling that I have transgressed now beyond the scope of our paper, I must put a brake to my inclinations.

. . . . . .

As a matter of news I might call attention to the new building of the Mutual Life Insurance Company that is being put upon the ground formerly occupied by the old post-office, a miserable excuse for a Government office that will be familiar to our readers who were acquainted with New York ten years ago. The location is on Nassau Street, extending from Cedar to Liberty Streets. The old place served at various times during its career as church, riding school, dog pit, and post-office, ending its career as a broken-down auction room and a succession of delapidated private offices, mostly devoted to beer, billiards, and young lady type writers. The wretched structure was torn down, and as if to complete the diversity of its experiences several bodies were discovered amid its foundations. This is the site of the New Mutual Life Company's building, and the situation is in a measure worthy the labor they are putting upon it. Nassau Street is one of the busiest thoroughfares in the city and one of the narrowest streets in the country, shut in by large houses rising seven or eight or ten stories toward the sky. The Mutual can only hope to shine and be distinguished by piling story upon story until it towers above all others. And this is the idea. It is to be 190 feet tall, overloom everything about it, and hopes to fly from its lofty towers the signal flags of the weather bureau's survey, now monopolized by the Equitable Insurance Company by virtue of their extreme height, but their laurels seem now to be endangered and bid fair to rest upon other brows. The new building is up only one story and gives but little idea of its architectural character excepting that it will be substantial rather than ornamental and less decorative than massive. The material is granite, and already there is a profusion of polished columns that is really perplexing, and the round corners of the building, if carried up its entire extent, will give a finish that will be novel and agreeable.

Dio Lewis' Monthly.

A NEW aspirant for the favors of the public appears upon our desk under the above title. The author is so well known that we have no doubt but that he will gather in many of his admirers on his subscription list. Terms, $2.50 per year.

Wooden and Brick Buildings, 2 vols. Price $18.00.

Street, Store and Bank Fronts. Price $4.00

Labor Strikes.

DURING the past three months the "striking" spirit seems to have taken possession of the laboring classes in almost all lines of labor operations. The prosperities of the last three years, which have gladdened all hearts and furnished employment to all classes of skilled and unskilled labor throughout the country, has awakened and stimulated in those who plod along from year to year under the yoke of labor, enforced by necessities in the obtainment of daily bread, the determination to seek relief in fewer hours of labor, in increased compensation, and the right to regulate the methods, rules, and equities of labor, so as to relieve it of all unnecessary hardships, and secure to those obliged from force of circumstances to walk within its restricted limits, all the reliefs and comforts possible; all of which are but the natural results of a prosperous condition of affairs generally, in which the masses of mankind feel that they have common rights, and should enjoy proportionately the benefits flowing and maturing from such general prosperities.

There is in every right-minded man that lives, the desire and ambition to better his condition. This is one of the greatest incentives to human action, and the beacon light that encourages those who would otherwise settle down in the gloom of "nothing beyond." But some are more successful than others in this universal reaching after and grasping the gifts of fortune—some gathering in and securing millions, while the greater number accomplish but little more than the securement of daily bread; yet the *right* to possess and enjoy an equal share of this world's goods is co-equal in all, although the qualifications to this end are vastly disproportionate. Still, with the enlightenments of the present age, the daily plodding, toiling multitudes will not quietly submit to some of their own blood and race being enthroned upon altars of gold, and clothed in habiliments of luxury and wealth, while they remain dependent upon and bound down to the slavery of labor, requiring all the working hours of day and the full strength of manhood, yet yielding no more than a mere subsistence. Hence the numerous disquietudes and uprisings which vitalize into strikes, and which as a rule inflict as great injury as benefit; but the battles will be renewed from time to time, both the workers and employers utilizing the advantages of circumstances and conditions as they present and repeat themselves, under the ever-changing degrees of prosperity which surround all business activities upon land or sea.

The Inspector of Plumbing.

MR. JAMES E. SWEENEY, plumbing inspector appointed by the Board of Health under the plumbing law of this State, called at this office on the 4th inst. and expressed an earnest desire that the most cordial and friendly relationships may exist between himself, architects, owners, and contractors generally, with whom he may be brought in contact in the course of his official duties. He unquestionably enters upon his work with an honest purpose to carry out the provisions of the law creating his appointment, and being himself a thoroughly competent and practical plumber, as we and many others in the profession can testify, it is fair to anticipate that under his watchful care plumbing frauds will be matters of the past. But it will require resolute mechanical and executive abilities and energies on his part to hold in check and prevent the numberless "nigerisms" which have hitherto prevailed, until, with a certain class, good workmanship and honest dealings have become almost obsolete considerations, bringing upon the plumbing art reproaches and mistrust. But if the gentleman named will exercise qualifications as inspector in degree and force equal to his mechanical abilities there need be no fear as to the result.

THE rules and regulations require that drawings and sketches sufficient to represent correctly the run of sewers, and sections illustrating the arrangement of the soil and waste pipes, etc., through the building, are to be filed in the office of the Board of Health; and, if found not to be correct in any particular, Mr. Sweeney will promptly correspond with or interview the architect, and suggest the necessary changes.

THE matter of payment for this extra service will rest between the architect and owner, and may be made a direct and separate charge against the owner, or the expense thereof may be stated in the plumber's specifications, and the plumber be required to pay the cost thereof to the architect. If the latter course shall be pursued, the payment may be reached without calling the special attention of the owner to the matter. It is a common thing to include, "the plumber is to pay the cost and expense of making the water service connection," and to make the charge for the extra plans a like matter of specification will serve all purposes, insure the payment thereof to the architect, and do no injustice to the owner. And it becoming a fixed item under the law, owners cannot object to the method suggested, unless he prefers to pay the amount direct, in addition to the fee agreed upon.

The Chapter Improperly Reported.

THE *Bulletin*, in its report of the meeting of San Francisco Chapter, held the 3d inst., says: "The *law* relating to the inspector of plumbing was discussed, and it was apparent that it did not meet with approval of the majority." This statement is misleading and erroneous, as the fair inference to be drawn from the language used is that the *plumbing law* passed by the last Legislature of this State, which authorizes the appointment of an inspector of plumbing, was the subject matter of debate; while in fact said *law* cut but an incidental figure in the discussion, which ran exclusively upon the *rules and regulations* adopted by the Board of Health, which was freely discussed and criticised, all present agreeing that they were and are imperfect, inexplicit, and defective in several materially important respects. We should not notice this did it not misstate facts and misrepresent the views of members of the chapter. Whether such was the intent or not, it assumes the appearance of the *Bulletin* seeking to sustain and strengthen its repeatedly expressed opposition to the plumbing law, by making it appear that the architectural association of this city virtually indorsed our contemporary's views of the case—a something that has not been done, and will not be until experience shall demonstrate the impracticability and insufficiency of the law to regulate and correct the evils, for the correction of which the law was passed.

San Francisco Chapter, American Institute of Architects.

THE regular monthly meeting of the above chapter was held in the rooms of the Art Association on Friday evening, August 3, President John Wright presiding.

Minutes of preceding meeting were read and approved.

Mr. Pissis reported that his class was getting along finely. The regular place and time of meeting was Thursday evening, at the office of Wright & Sanders, between 8 and 9.

The several committees on incorporation of the chapter, room for the use of the class in carving, etc., reported progress and were continued.

A communication was read from the Rhode Island Chapter, A. I. A., informing this chapter that it was desirable that drawings, sketches, etc., should be received from the members of S. F. Chapter for exhibition at the National Convention of A. I. A.

The Secretary was instructed to notify the R. I. Chapter that the notice of time in which to prepare plans or sketches was too short to allow of members doing themselves justice.

N. L. Mayo was proposed for membership as student. The rules and regulations adopted by the Board of Health in regard to the new Plumbing Law were discussed. No action was taken.

Nominations of officers for ensuing term being in order, it was moved and seconded that the various officers now holding the different chairs be renominated. Amended so as to substitute H. C. Macy for Treasurer in place of the present incumbent, on account of the latter having removed his residence to Oakland. Also the Recording and Corresponding Secretary were united in one office, and G. H. Wolfe nominated for the dual place.

On motion, it was resolved that this chapter offer a premium of $30.00, in three prizes of $15.00, $10.00, and $5.00, for the best three designs for a seal for the use of this chapter, the competition to be confined strictly to the students in the profession.

CURLETT & CUTHBERTSON have removed their office to the Phelan Block, junction of Market and O'Farrell.

The Importance of Learning to Draw.

TRAINING in art is a means of education, of calling out faculties of the body and mind which would otherwise lie dormant, of opening sources of pleasure in an intelligent appreciation of works of art—people who do not understand art practically almost always admire bad things—and of giving, by means of the power of drawing, a more accurate perception of the forms of objects, and a capacity for representing and describing them in a manner far more direct and more universally intelligible than any written description can be. This practical value of drawing has been borne witness to by not a few employers of labor, who have given it as their experience that a workman who could draw and could properly understand a drawing was always more capable, more useful, and better able to carry out his instructions than one who could not. The practical value of drawing may be recognized, even apart from its operation on the understanding, in its power of promoting greater delicacy of manipulation in operations quite apart from that of drawing in itself. One of the best amateur artists of the day, as is well known, is an eminent surgeon who has declared that he first took up etching because it was a recreation which would have the effect of rendering his hand more delicate for his important professional work. One of the best remarks in regard to this result of training in drawing was given by a lady who was a candidate for a school board election, and was asked, somewhat indignantly, by one of her working-class constituents, what was the use of teaching drawing in the board schools to girls who were going into service, for instance; and why their education was not confined to things that would be useful to them in their future life? The reply given was that there was no more common complaint against female servants than about their clumsiness in handling fragile things, such as glass and china, and their continual breakage of such articles in consequence; and that a training like drawing would probably do more to render the hands more safe, careful, and sensitive to touch than any other influence that could be named. Of course, it might have been said in addition that a knowledge of drawing would give a domestic servant even greater advantages than that, in providing her with a more interesting and sensible occupation for her leisure time than reading "Penny Dreadfuls."

Probably the reform would be accelerated not a little if it were once fairly recognized that there is a practical value in the power of drawing for men who are in trade and commerce, and that it is not a mere accomplishment for ladies and gentlemen. In many schools the mistake is that drawing is only voluntary. Few school-boys are likely to do anything voluntarily in the way of work; and as drawing taught on the scientific method really is work, and not mere trifling with brush or pencil, it may be surmised that only a very strong turn for drawing on the part of the pupil, or the direct orders from home on the part of the parents, lead to the filling up of the drawing-class. Among university men of the present day, from which class most or all of the professors at our large schools are recruited, there still linger the remains of the old superstition, that drawing should be an "extra," somewhat like dancing; an elegant accomplishment, not to be put on a level with classics and history and other serious studies. The next generation of school-masters will probably know better themselves; to those of the present generation it may be urged that drawing is a most important element in mental and bodily training, and that up to a certain point—that is to say, as far as concerns the practical handling of the pencil and the power of copying an object when seen, and of drawing in correct perspective anything which it is desired to represent—so far as this, drawing can be almost as certainly taught generally as writing, and ought to be so, as a part of every man's education. The question of artistic feeling in the higher sense is a different one. It only exists at all in a portion, perhaps a minority, of boys; though a preliminary training in practical drawing might not infrequently bring out evidences of latent artistic taste, where it would never have shown itself or been suspected had not the capability for the expression of it first been imparted. The true solution of the problem for general schools would be a compulsory class, supplemented by a voluntary one. The elements of drawing, scientifically taught, should be as much a compulsory subject as grammar or writing; and when once this is established, we should not have the curious spectacle, which we have sometimes seen, of great publishing firms which would on no account publish bad and ungrammatically-written books, being quite willing, nevertheless, to publish books containing illustrations violating the first rudiments of the grammar of drawing and perspective, and seeing nothing to be ashamed of in this; and after the course of a few generations of compulsory teaching of drawing, people will read about the people who could not draw in the present day as we do now about barons and knights who could not write their own names. —*Art Interchange.*

The Mound Builders.

AT the annual meeting of the Boston Society of natural History, a highly interesting statement was made by Prof. F. W. Putnam, Curator of the Peabody Museum of Harvard University, concerning his recent explorations of certain mounds in the Ohio Valley. The subject was illustrated by drawings hung upon the wall, and by photographs. These explorations, in which he was assisted by Dr. C. L. Metz, of Madisonville, Ohio, were made last year, and were restricted to one particular mound field or tract upon the borders of the Little Miami River, in Madisonville, about twenty miles from Cincinnati. It is to be regarded as one of the felicities of the event—for the work and its results constitute an event in the full significance of the word—that, being situated so near to one of the great cities of the land, it has happened that no persons impelled by mere idle curiosity have hitherto dug into these mounds in a random way, and thus practically destroyed them in respect to their special value to the archæologist. The excavations now made were conducted on the most approved methods of science. Nothing worthy of notice has escaped observation and record, and every relic has been carefully preserved for scientic purposes. In the brief discussion which followed the Professor's statement, one of the members of the society declared the results thus reached to be the most important discovery yet made in American archæology. Several of these mounds were what are called "altar mounds," and in these the valuable and instructive relics were found. These, in number and variety, were sufficient in themselves, if none others had ever found, to give a very distinct—it might almost be said comprehensive—idea of the civilization of the social state of the ancient mound builders. Among other things found were articles of personal adornment, such as ear-rings of pearl and bracelets of metal. The precise advance of the art of working metals is thus disclosed. The metals had been wrought by hammering the ore. Molten work was beyond the skill, or rather the knowledge, of the artificer. The metals were iron, copper, silver, and gold. This is the first time gold has been found in the mounds. The gold, and in some instances the silver, was used for plating an inferior metal, being hammered thin and clinched at the edges. Most significant of all, perhaps, was a little statuette, which not only presented the human form in a shapely—it might almost be said artistic—contour, but showed also the ear-rings and the drapery of the waist which were fashionable in the American prehistoric times. Some of these relics must originally have come from the Florida coast, from Lake Superior and from the Rocky Mountains, indicating thus either extensive migration or intercommunication. The indications are that cremation of the dead was practiced by these natives, and that an altar mound is significant of some great sacrificial ceremony, and that these trinkets and relics, some of which pertained to the useful arts, represented an offering on the part of these people, equivalent, in comparison with our scale of values, to hundreds of thousands of dollars.—*The Mechanical News.*

THE greatest obstacle in the way of forming definite conclusions from experiments is the fact that, generally, more than one experiment is tried at the same time. Hundreds of experiments that count for nothing would have been valuable in advancing both general and specific knowledge, if between them and others with which they are compared some addition or alteration had not been made, the presumed influence upon the result leaving the latter problematical.—*American Machinist.*

Plasterer's Manual, enlarged. Price 75c.

☞Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas, send us a sketch of them and we will make the cuts.

O. T. C.—A two (2) inch hole is bored in a green or unseasoned plank. When the plank becomes seasoned, will it affect the diameter of the hole, or will it still remain two inches?

Yes. The diameter of the hole will be less than two inches, and will be found to be somewhat elliptical in form, the contraction being greater across than on the lines parallel with the fiber of the wood.—*W. C. S., in the Artisan.*

Method of Obtaining Length of Rafters.

FOR some months past there has been quite a discussion of various plans for obtaining the length of rafters. Many of the methods presented are not desirable, for the want of accuracy. Some years ago the subject came up for discussion where I was at work, and I then prepared the following table, which is very simple and mathematically correct. Any mechanic can copy it on the back of a business card and tack it to the lid of his tool-chest, where it will always be handy for reference. The word "pitch" means such a fractional part of the width of the building. The further north you go the steeper the pitch, on account of the snow; also certain localities have pitches peculiar to that section of the country:

Pitch.	Square.	Rafter.	Brace.
1-6	4 and 12	0.527046	1.054092
5-24	5 and 12	0.541666⅔	1.083333
1-4	6 and 12	0.559017	1.118034
7-24	7 and 12	0.578852	1.157704
1-3	8 and 12	0.600925	1.201850
3-8	9 and 12	0.625	1.25
5-12	10 and 12	0.6508541	1.3017082
11-24	11 and 12	0.6782843	1.3565686
1-2	12 and 12	0.7071068	1.4142136

The first column indicates the pitch of the roof; the second gives the figures on the square that will cut the various pitches; the third gives the length of a rafter for a building one foot wide, and the fourth gives the length of braces for runs of the same proportion as the figures in the second column.

The manner of using the table is as follows: For any given pitch multiply the tabular number by the whole width of the building, and the product will be the length of the rafter in feet and decimals of a foot.

Example.—What is the length of a rafter of a building 18 feet wide at ⅓ pitch?

Solution.—0.600925x18=10.81665 feet, or 10 feet 9 13-16 inches.

Example.—What is the length of a brace having 40 x 48 inch run?

Solution.—40 x 48 inches is the same proportion as 10 x 12; hence, 1.3017082x48=62.482 inches, or 62½ inches, always using the longest run for multiplier.

Example.—What is the length of a brace having 35 x 35 inch run?

Solution.—1.4142136x35=47.4974 inches, or 49½ inches.—*S. R. K., in Carpentry and Building.*

Modern House Painting. Price $5.00.

A Handsome Illustrated Catalogue.

WE have received from the Robert Mitchell Furniture Company of Cincinnati a very elaborate illustrated catalogue, containing 307 pages, of parlor and chamber sets and house and office furniture and fixtures of endless variety and in every conceivable style and design. Expense has manifestly not been spared in producing the catalogue, and those desiring elegant things in the furniture manufacturing art will do well to consult its pages, as any and everything of the character necessary to the comforts of home life, and to furnish beautiful surroundings and equipments, will be found fully illustrated.

Lessons on Hand Railing. Price $5.00.

Workshop Virtues.

OBSERVATION is the first lesson the apprentice learns. When fresh from school he is introduced into the new world (the workshop), and he sees about him a number of men and of tools, and of the names of the latter, or their uses, he knows practically nothing. Machines, wheels and shafts, some in motion and others at rest, stare him in the face until he is somewhat bewildered and he is apt to exclaim, like the "heathen Chinee," who was viewing a marine engine for the first time, "Too muchee wheelee, make man thinkee too muchee." After a day or two this feeling of bewilderment fades away—use becomes second nature to him. Now is the time to improve himself and awaken his faculties, if he has the will. Let him observe the various machines and processes, try to understand why one machine runs at one speed and another at a different one, and why one process is dependent upon another—in fact, make use of his powers of observation, try to remember what he sees, and consider whether he can suggest an improvement. If he can make notes at home of an evening, so much the better; he will find the habit exceeding useful. By observation, errors may be detected in work about to be executed before the blunder is actually committed, thereby saving both time and money.

In some measure all workmen are obliged to be punctual in their going to and leaving work. The bell rings or the whistle blows at fixed hours, and the workmen must be governed by these signals; but over and above these fixed times, the habit of punctuality is a valuable one. Some factories are famous for being faithful in the fulfillment of their promises as regards time of delivery; they will work night and day to complete an order by the specified time. Others, again, are noted for their utter disregard of time.

Every foreman or manager knows how pleasant it is to deal with a workman ready at taking a new idea, or willing to try a new method of doing work. These are the men who distinguish themselves, and obtain better position than those who cannot move out of their rut of habit. So, also, a firm becomes noted for adapting itself and its resources to new trades or methods of doing work, while a firm which will not try an experiment will be pushed out in the cold in the struggle for existence. The man who knows the reason for what he does is a better man than he who only does a thing because he is told to do it a certain way. Every mechanic should understand, for example, why his drill should run faster for a small hole than for a large one, why one speed of tool is suitable for one metal and not for another.

If he is a smith, he should know why steel is worked at a lower heat than iron; what conduces to a sound weld, and why a piece of steel broken haphazard off a bar cannot be drawn to a sharp point without certain precautions. There are principles underlying every trade which is to the interest of the artisan to study, to ponder over, aye, and even to discover, for it is well known that there are principles yet undiscovered which the cultivator of the various workshop virtues may be lucky enough to fathom, with honor to himself and benefit to mankind at large.—*Mechanics.*

Stables, Fences, Out Buildings, etc. Price $2.50.

THE KIND OF NAILS.—At first the extra cost of steel nails was one and one-half cents per pound, or $1.50 per keg, but it has now been reduced to $1.00. The great advantage of the steel nails is that they can be driven into hard wood as easily as an iron nail will go into a pine board. Steel nails have been driven into a white oak knot without bending. Nothing else is now used in laying hardwood floors, as they require no boring, but are driven readily. For all kinds of finish they are especially adapted, and as so much hard finish is now employed, their use must be on the increase. They are also used largely by builders, and box-makers are increasing their demand for them. Box-makers have been using the better grades of iron nails, as they desire those that can be drawn and redriven.—*Northwestern Lumberman.*

School House and Church Architecture. Price $4.00.

Sample Copies.

Hereafter we will forward no sample copies of this Journal unless the price, twenty cents for each number, accompanies the order.

Warping of Drafting Boards.

I HAVE taken many valuable hints from *Carpentry and Building*, and I wish to contribute my mite to the general information presented. Those who have used drafting boards appreciate their liability to warp under various conditions of atmosphere. It is also pretty well known that almost fabulous prices are demanded for good drafting boards at the hands of dealers. I have discovered a method by which an ordinary drafting board can be constructed that will remain in good condition. I had some large detail drawings to make in California many years ago, and, being a carpenter, I made a board for the purpose in the quickest manner I could. I glued the joints, and, as battings suggested themselves, I employed them in its construction. The board measured about 40x80 inches in size. I dressed one side and cut three beveled-edged battings and fitted them to one-half the thickness of the board—in other words, I dovetailed them in such a manner as would allow them to slide and not interfere with the shrinkage of the board, and then went to work with my drawings. In a few days I was compelled to stop, as my board had warped three-quarters of an inch, taking the battings with it. I then grooved the under side one-half the thickness of the board at distances of two inches. The grooves run in the opposite direction to the battings, or with the grain of the board. When this was done I found that I had the most perfect drawing board I had ever used. I think others will find the suggestion advantageous.—*Palmetto, in Carpentry and Building.*

A Good Hint to Workmen.

THE old saying that "a man is taken by the coat that he wears," applies to journeymen plumbers. Show us a man that loses his self-pride as to his appearance, as a general rule he also becomes careless in the work he performs. On the other hand, a man that has a good appearing tool-bag, containing tools requisite and necessary to perform a good job of plumbing, also keeps himself clean and tidy, it is a sure indication that he can perform a good job of work. How often do we have the question put to us by our customers when ordering work done, "Will you send me that last man that done our work?" Why? "O, because he attends to his business; don't fool with the girls; goes about his work in a workmanlike manner, and don't mess and dirty the entire house up, and tear the woodwork of the whole house apart. If you can't send him I would prefer waiting a day or two until you can." Ain't this satisfactory proof to a boss? Yes; and these are the men that study their own interest as well as the bosses', and an ornament to any trade or profession.—*Plumber's Trade Journal.*

THE daily cut of the mills on Columbia River, Oregon, is 650,000 feet. About $1,000 worth of logs are daily floated out of John Day's River. The mills of Astoria and vicinity daily cut $150,000 worth of lumber.

A List of Registered Plumbers up to Date of This Issue.

IN accordance with the requirements of the new Plumbing Law, the following parties have been registered. It is imperative that every plumber, be he master or journeyman, shall have his name and standing registered at the office of the Inspector of Plumbing. The office is on O'Farrell Street, west of Dupont, in the same building and in connection with the Health Office. In our next issue we probably will be able to give nearly a complete list.

M stands for Master Plumber. They are required to file a bond for $500. J stands for Journeyman:—

Adams, John L., 9 Clara Street. J.
Ayers, Chas., 909 Larkin. J.
Byrne, Jas., 119 Welsh. J.
Berwick, David, 937 Mission. J.
Broad, J. F., 1222 Bush. J.
Cardiff, R. J., 319 Tehama. J.
Cusick, Jas. E., 937 Mission. J.
Connor, J. H., 528 Third. M.
Dixon, J. J., 1222 Bush. J.
Doyle, J. P., 214½ Sixth. J.
Doggett, B., 116½ Langton. J.
Duffy, G. F., 2096 Market. J.
Daniel, W. L., 234 Post. M.
Dunn, W. J., 37 Louisa. J.
Enright, Wm., 1115 Devisadero. M.
Ellis, T. P., 668 Mission. J.
Ford, Thos J., 404 McAllister. J.
Flood, Jos., 753 Harrison. J.
Fritz & Kean, 130 Geary. M.
Firmin, J. E., 240 O'Farrell. M.
Gray, W. J., 1 Webster. J.
Gray, J. T., 230 Sutter. M.
Holden, C. S., 824 Green. J.

Snook, Edgar N., 726 California. J.
Wilson, W. F., 25 Stockton. M.
Waters, Chas., 30 O'Farrell. M.

It is imperative that all plumbers should be registered, as they are not allowed to work on buildings without a permit, and the sooner the matter is attended to the better, as permits will not be granted unless the parties are registered.

The above list includes all that are registered up to the time of our going to print.

Discoloration of Brick Walls.

WITHIN late years the great popularity of brick as a building material and the great increase in the number of brick edifices which have been erected have brought into prominence a matter which could not have escaped the notice of the most casual observer, namely, the disfigurement of brick walls from a coating of white powder resembling in appearance hoar frost or mildew.

These deposits are usually formed in rainy weather, and for a long time it has been a mooted question how this substance comes to be collected, what it is, and what can be done to remove it or prevent its formation. The rains of this spring seem to have been especially favorable to the forming of these deposits, and old buildings even, which hitherto have never been defaced by this substance, have this year given up their ruddy appearance for a paler and less attractive complexion. Dr. Joseph Leidy, President of the Academy of Natural Sciences, in speaking of this subject recently said:—

"The efflorescence is simply ordinary Epsom salts or sulphate of magnesia. The sulphurous acid, which results from the burning of coal, combines in the presence of moisture with the magnesia in the mortar or from the clay in the bricks. It was decided that it emanated from the former source. The sulphate of magnesia dissolves in the water, which runs over the bricks, and, evaporating, leaves the deposit. Some walls are covered with a black substance which seems at a distance to be smoke. This is a fungus, which flourishes in damp places, and is materially different from the white sulphate." Dr. Charles M. Cresson explains in a similar way the method by which the substance is deposited on the walls, but expresses the belief that it is sulphate of potash. Edwin F. Durang, the architect, said that sulphurous acid acting on the mortar decomposes it to such an extent that chimneys had often to be rebuilt on account of it. He thought the efflorescence was sulphate of lime.—*Scientific American.*

STRAW lumber has been very much exaggerated, though it may be reckoned considerable of an invention. An Eastern enthusiast recently stated to a newspaper interviewer that there were "scores of mills in the country where paper, straw, prairie grass, and other fibrous substances are converted into straw boards, which are sold all over the country as substitutes for wood." This may be taken either as deplorable ignorance, or an ingenious statement. There is but one factory at present where straw lumber is being manufactured so as to cut any figure. Paper boards—building paper—are made all over the country, and are used to some extent in place of wood, but they are only paper, pure and simple, and lay no claim to being a substitute for lumber, and are more a substitute for plastering.—*N. W. Lumberman.*

Public Buildings. Price $4.00.

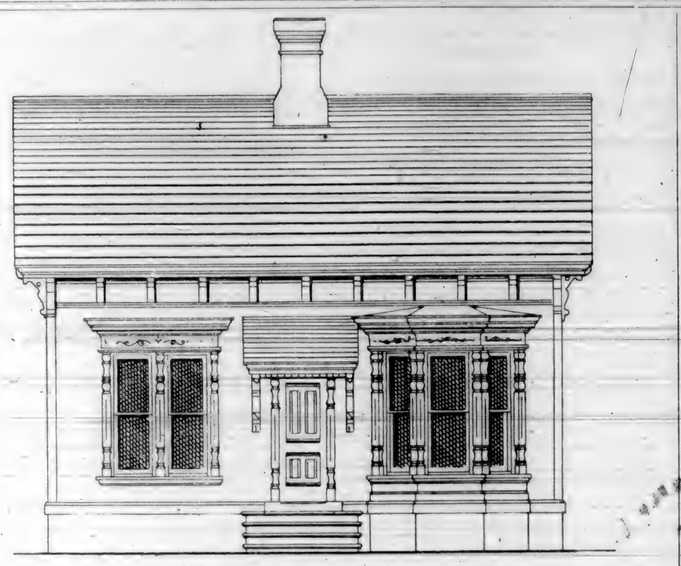

PLATE 4.—FRONT ELEVATION OF WORKINGMAN'S COTTAGE, COSTING $1,500.

The Board of Health and the Plumbing Law.

THE Plumbing Law, passed by the last Legislature of this State, went into practical effect on the 1st inst., under the rules and regulations adopted by the Board of Health of this city and county. Said law being the first enacted in California for the purpose of regulating and controlling the customs, methods, and execution of a special branch of mechanical works, it was to be hoped that those empowered to give it shape and vitality would have exercised all the care and practical, mechanical, and scientific intelligence necessary to its complete efficiency. And we regret that the rules and regulations adopted by the board in this case do not warrant us in stating that they are *fairly* perfect. It may be that to the learned gentlemen composing the board the whole matter contemplated by the statute was so plain and simple that they deemed it unnecessary to spend much time in framing a set of rules and regulations, and therefore paid no attention to the ambiguities, inexplicitness, and imperfectness of those adopted.

There are many reasons why this should not have been, and why an exceptionally perfect set of rules should have been provided: *First*. Plumbing laws exist in several of the Eastern States and are in practical operation, and the rules and regulations by which they have been rendered operative and efficient were available to the San Francisco board and might have been consulted. If this has been done, the result developed in the rules adopted by our Board of Health are not calculated to reflect any great amount of credit upon the rules in practice in Eastern cities.

Secondly and mainly. If, from imperfect rules and regulations, or any other cause, the plumbing law of this State shall prove a failure, it will discourage all future legislation upon matters looking to the relief or protection of other mechanical operations. In this view of the case, all branches of mechanism are interested in the success of the law under notice; for if an effective law cannot be passed regulating plumbing and sewer works, then it is doubtful whether Legislative protection can be thrown around any other of the mechanical arts.

We will not, however, enumerate further, nor refer in detail to the errors and deficiencies in the rules, knowing that the board, together with the gentlemen most in interest, the plumbers, are fully competent to discover and correct such mistakes as may have been made.

Artistic Homes. Price $3.50.

Coterminous Ownership—Rights to Excavate.

PRIOR to July, 1880, the city ordinance relative to and defining the rights of owners in the excavation of their lots for the purpose of building, was generally observed in practice. Said ordinance provides (sec. 5, chap. vi, order 1281, as amended May 16, 1876) that owners about to erect buildings, etc., shall have the right to excavate to a depth of fourteen (14) feet below the curb level, without incurring any risks or responsibilities in reference to adjoining property or structures, except to serve the proper written notices. This understanding of the matter was so general that adjoining owners seldom refused to take care of and underpin the structures upon their premises. But in the July, 1880, number of this journal, we published the decision of the Supreme Court in the case of Zeile *vs.* Hood, which virtually set aside the city ordinance, and by, as we think, an irrational and illogical construction of sec. 832, civil code, sustained the decision of the Fourth District Court, Judge Morrison then presiding, which decision imposed upon the party excavating (Hood) the responsibility and cost of under

PLATE 5.—SIDE ELEVATION OF WORKINGMAN'S COTTAGE.

PLATE 6.—FIRST FLOOR PLAN OF $1,500 COTTAGE.

pinning the adjoining owner's (Zeile's) building. The decision of the higher court becoming generally known through the columns of this journal, owners of improved property have since acted upon the defensive by refusing to be put to any expense in underpinning their buildings, and those making new improvements have been compelled to bear the cost of sustaining the adjoining property, or suspend building operations. But the present Supreme Court, in the case of Aston respondent, *vs.* Nolar, appellant, has reversed the decision in the case of Zeile *vs.* Hood, and virtually restores the city ordinance, which gives to all owners the rights and privileges hereinbefore stated. This result is in exact harmony with the views expressed by us at the time of presenting the Zeile and Hood case, in which we held that *"the vital point in issue had not been finally settled and determined"* by the decision then referred to; and so it has proven; for the section of the code quoted is without shadow of reference to the party excavating sustaining the structures erected upon the adjoining property. (For full report of the case of Zeile *vs.* Hood, see this journal of July, 1880).

In plain words the case now stands thus: Every owner of real estate has the right to excavate his premises to a depth of fourteen (14) feet below the curb level, without regard to adjoining structures, provided he shall first serve a written notice upon the owner or owners of the adjacent property, notifying him or them of the intention to, and extent of, the intended excavations. And the owners of adjoining property or buildings are required, under the decision of the Supreme Court, to take care of and underpin at their own cost and expense. Any doubt that may exist in the mind of any one can be set at rest by calling at the office of this journal, and examining the law and decisions bearing upon the case.

Swiss Gothic Cottage.

WE have received a supply of the above from Palliser, Palliser & Co. It is a large sheet on which are given elevation and plans of a Swiss Gothic Cottage. By an easy modification it can be built either as an eight or six room cottage. Full details are given. Price, postpaid, $2.50.

WHAT CAUSES THE TIMBER LINE?—A writer in the New York *Independent*, says: The cause of what is known as the timber line on high mountains continues to be discussed in scientific periodicals, and the attempt continued to connect the line in some degree with mean annual temperatures. The writer of this paragraph has had the matter in mind when on these high elevations, and the explanation seemed very simple. On all these high peaks there is a continuous, though in some cases slow, descent of the soil from the summit to the base of the hill. He has never seen a case, where there was soil enough to grow a tree, that trees were not growing. As the wash from rain or melting snow will be nearly uniform in a given range, there will be of necessity some uniformity in the timber line. On Mount Washington and other high places, little plots of dark vegetable earth can often be found far above the present timber line, the remains of trees which existed before the earth was washed away. What is called the timber line seldom shows graduated sizes, as a mere matter of temperature would call for. Generally the line is formed of very small trees, and immediately scrubby plants, from the absence of deep soil, begin.

THE California Redwood Company has been formed by English lumbermen, with a capital of $4,500,000. The object is to purchase redwood timber lands in California, and ship the product across the water.

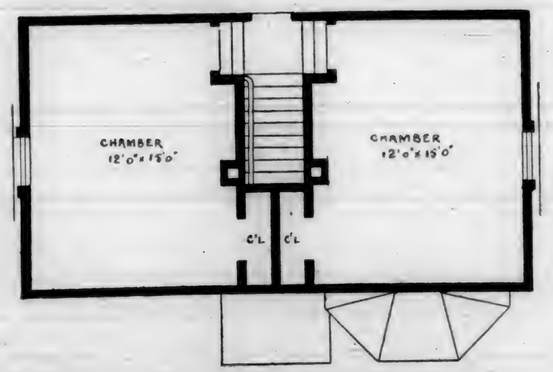

PLATE 7.—SECOND FLOOR PLAN OF $1,500 COTTAGE.

Exterior Stains.

[From the American Architect and Building News.]

STAINS for exterior use may be divided into two classes: first, those in which the coloring material is actually dissolved in the vehicle; and second, those which are colored with a very finely divided insoluble pigment, mixed with sufficient fixative to make it adhere firmly. Stains of the latter class are therefore merely very finely divided paints. The first class where applicable, is, in the writer's opinion, superior to the latter, as the grain of the wood in the clapboards or shingles is rather more distinctly and vividly brought out. On the other hand the number of colors is very limited which admit of this application. A few of the colors of this description which have been thoroughly tried by the writer may here be enumerated.

American Asphalt	Brown
Trinidad Asphalt	Brown
Resin Asphalt	Reddish Brown
Aloes Gum	Greenish Yellow
Yellow Gum	Light Yellow
Alizarine	Red
Annotto	Red
Eosin	Red
Dragon's-Blood	Red
Azo Yellow	Yellow
Amin Yellow	Yellow
Methyl Green	Green
Malachite Green	Green
Nigrosin	Blue Black

It is useless to extend this list farther, for the writer has tried almost all the known colors that can be brought into solution in oil. Unfortunately, of this list only the first six are upon careful trial sufficiently fast to be used for exteriors, and of these alizarine is too expensive at present to admit of use except for some special occasion where price is not considered. The remaining ones would many of them answer for interiors, but the combination of rain and sunlight disposes of them outside too easily. We are therefore limited to a very narrow range of colors of this character, and must turn to the second class of colors, viz., those consisting of insoluble pigments with a fixative to hold them on to the fiber of the wood. With these we can obtain almost any desired shade, and if properly ground pigments and suitable vehicles are used, effects can be obtained almost equal to the colors of the first class in respect to showing the grain of the wood. The writer has found the best pigments to be pure oxides of iron (exceedingly finely ground) for the reds, yellows, and browns; pure chromate of lead for lemon yellow; mixtures of these with black and blue pigments for greens and olives. The greatest care should be used in selection of pure and very fine pigments. For a vehicle the best seems to be a purified creosote oil, which practically renders the wood imperishable and is moreover comparatively inexpensive. Linseed oil may of course be used, but it has one difficulty which every one must remember who has seen a lot of old painted shingles taken down. Just behind the butt of the shingle or clapboard is seen a deeply corroded or decayed spot upon the under side, where the water has been held in between that shingle and the next by the paint, which forms a *cul-de-sac* in which the moisture collects and causes the decay; this is due to the "skin" formed by the drying of the linseed oil, and is not to be found if creosote oil be used in place of linseed. In conclusion the writer would say that he thinks the best way of treating either a clapboard or shingle is to dip about two-thirds of it in the stain, which should be kept well stirred. It should then be allowed to drain back into the pan or barrel by being put into a wooden trough tipping backward, and then should be thrown out on to the grass or clean ground to dry for three or four days. Many houses are built in which the shingles are stained and the clapboards painted. The result would be much finer if both were stained, for stain has the effect of making the whole side of a house look as if it were treated in detail, so great is the beauty and variety of the grain of the wood, while paint reduces the whole to a monotony in which the color *en masse* is the only effect. Any inquiries which the writer can answer will receive the attention of

Yours sincerely,

CHEMIST.

Builders Guide. Price $2.00.

The Practical Advantages of Trade Journals.

WHAT commerce does to stimulate the industries of the world, the trade journal does for the trade it represents. It would be difficult to name a trade of any importance which is not represented by its journal. The reason of this is clear enough to those who know how much absorbed good workmen are in their calling, and how anxious they are to know what is going on in their own immediate world—what improvements and developments are taking place; what is new, and what becoming obsolete. As the daily paper presents to the general public reports of notable events in the social, political, and commercial world, so the trade journal culls all facts bearing on the interests it represents, and furnishes them to its readers.

The importance of trade journals is indicated by the fact that they are wholly supported by the trades that each represents, and cannot be said, to any appreciable degree, to be read by the outside public. And this condition of things is quite natural, because every one takes the greatest interest in what most intimately concerns himself, and the journal of greatest value to the tradesman is that which has something instructive and encouraging to say about what he is doing, and about what others in the same trade are doing. Some shrewd observers of human nature maintain that the nature and quality of a person's reading, and the departments of a paper to which he turns with greatest eagerness, are sure indexes to his avocation.

Notwithstanding the cordial support given to trade journalism in this country, it may be said that it is not wholly understood or appreciated by those most interested. Much more could be made of it if its readers were only to consider themselves as contributors and correspondents. There is probably no member of a trade or profession who does not wish to know something or have some doubt removed. There are probably few, whether employers or employed, who have not discovered something in their special calling which, if known, would be of practical value to those of his own trade. Many of the best workmen hesitate to take up the pen to enlighten others, though they are willing to do so, and know that they have ideas which would be helpful to their fellows, simply because they cannot turn out their sentences in a style which they consider proper for a widely-read paper. This is largely due to false modesty, and perhaps through indulging in many a brilliant idea, and often a valuable invention or suggestion of real practical utility is buried in a man's bosom, and dies with him. It is the idea, and not the language which clothes it, that is important. It is the diamond, with its bright sparkle, and not the setting, however rich, that attracts the eye. So the tradesman who has developed anything new in thought or in actual experiment, is in duty bound to give currency to it for the benefit of his fellow workmen, where this can be done without too great pecuniary sacrifice. The gospel parable reproves him most severely who wrapped his talent in a napkin and buried it.

If all artisans and mechanics were to consider their own trade journals as the storehouse for their ideas, and a free exchange for all communications affecting their calling and interest, every journal of this class would grow in importance and general interest. It would be a means of improving their condition, enhancing their skill, stimulating original thought, awakening a more friendly feeling among mechanics, and possibly effecting a better understanding between employers and employed.—*British and Colonial Printer and Stationer.*

"First Class."

A LARGE share of the misunderstanding and consequent confusion and trouble in the world seems to come from the lack of an absolute standard of excellence. This is especially the case in matters connected with building. It is a never-ceasing source of amazement to tyros that the estimates, made by thoroughly good, responsible, and intelligent builders upon any given piece of work, for which plans and specifications have been prepared by equally intelligent and experienced architects, should vary so widely. It is by no means an uncommon thing for the estimates of different contractors to vary from ten to thirty per cent., and instances are not wanting where one builder has offered to do work for half the price proposed by another. But a short time ago estimates were made upon a dwelling house in this vicinity, the plans for which had been prepared by one of the best firms of architects in the country, and the lowest figures were $22,000, the highest $37,000. A still greater variation occurred in estimates for finishing certain departments of a public building whose history is familiar to many people, the highest being between $42,000 and $43,000, the lowest between $18,000 and $19,000; these estimates were based upon the same plans, the same specifications, and there is no reason to doubt that the men who made them understood the same thing. It certainly is difficult, even for professional skill, to account for these differences, yet it is a part of the experience of every one who has to do with building or with preparing plans for the same. To a large extent this is owing to the lack of thorough training, that is, to this want of an absolute standard of excellence.

"First-class" work does not mean the same thing to men who are differently educated, and, although the phrase is constantly occurring in the written description of work, it is indefinite in its practical application. To one who has had the advantage of a thorough training and practice upon the best kind of cotemporary work, it has a distinct meaning with reference to what he has already done; but to one who has had no such experience, and whose best work would seem to the other entirely unworthy and inexcusable in a given case, it means something entirely different; *i. e.*, although both read the same words, yet judged by the same standard one agrees to perform that which is many times greater in value than the other. Referring to the details of work it is impossible to estimate the value of the labor required to execute anything which depends upon the skill and intelligence of the workman. A spindle, revolving a fixed number of thousand times a minute, may be depended upon to turn out a fixed amount of yarn in a given time. It is not possible to measure the capacity of a workman in the same way. He may drive a nail with two blows or three; he may smooth a board or straighten a joint with five strokes of the plane or ten; he may cover a square yard of lath with plastering or of clapboards with paint in five minutes, or it may take him ten; and this variation carried out through all the details makes the difference between the $5,000 or the $10,000 of the aggregate estimate. Hence it follows that the greatest uncertainty usually appears in those structures or parts of a building in which manual labor is the chief item of cost, and the buildings in which this occurs are not alone those of elaborate and expensive workmanship, but those which deviate in their style and manner of construction from conventional and familiar modes. This latter fact accounts for another peculiarity that is often referred to as one of the unaccountable points in building; that is the difference between ready-made houses and those which are built from special plans. It is easy to duplicate the cheap, every-day styles of building—those with which every mechanic is familiar in every part, from the thickness of the cellar wall to the pattern of the scroll-sawed bracket—but a house of precisely the same size, precisely the same amount of material, and requiring actually the same amount of labor, will be found more difficult to estimate in proportion as it appears to contain more unknown quantities—not necessarily larger or more complex quantities, but they are unfamiliar, and neither contractor nor workman undertake them with as much confidence and expedition. The practical remedy, as far as it appears at present, for this unsatisfactory state of affairs,—for it is unsatisfactory, begetting distrust and disappointment continually,—is the more thorough training of workmen, the dissemination of such technical skill as will give to mechanics and builders not only better facility in doing work, but a more reliable standard of excellence,—in brief, technical, industrial education. It follows, without the need of saying it, that when contracts must be made the only safety lies in keeping clear of all but thoroughly competent and reliable contractors.—*The Builder.*

Village Builder. Price $10.00.

Rights of Owners of Buildings.

IN referring to the right of owners of buildings, we have not in view such covenants as they may make with tenants, and in which they are secured, but those which exist for compensation for damages inflicted at the instance of neighboring owners. The most unquestioned claim exists where the latter so carry out excavations as permanently to weaken foundations or cause subsidence of adjoining building, thus affecting the value or rentable value of the property, and possibly endangering its maintenance. We may state at the outset that owners of buildings in this country have fewer rights than those generally possessed by their class abroad. The laws in England and on the continent are singularly minute and exacting as to what constitutes special damage, and builders are proportionately embarrassed. In England, the erection of a building can be prevented, so far as it will obstruct the light or interfere with the view from the windows, should such windows have existed for the term of twenty years. These "ancient lights" are jealously protected by the courts, even though pertaining to premises old and dilapidated. Such a legal provision would never consort with our city improvements. On the other hand, as respects the effect of the erection of one building on another, the Supreme Court has held that no compensation can be obtained for indirect damage. It is not even clear that the damage occasioned to houses by the vibration caused by the running of trains on the elevated railways, constitutes a claim for compensation on the part of aggrieved parties, the cases in which they have taken action being yet unsettled among the appeals to higher courts. An instance of a clear case, allowing of compensation, is when the preparation of the foundations of a building causes damage to the neighboring property under different ownership, by subsidence, owing to excavations being carried too low down; or carrying these on beneath such property without proper underpinning, or neglect sufficiently to shore the side wall; or, furthermore, when by injudicious or overcharged blasts detriment of various natures result. But where a building is entirely removed, so as to take away the support which the adjoining building, owned by another party, has enjoyed, the question as to whether a suit for damages can be sustained becomes complicated, for a reason set forth by the *Building News* in treating of damage to buildings, English rulings on this point being followed.

"In theory, the law supposes, for the purpose of a claim, the owner of the servient house to have been acquainted with the fact that his own building was necessary for the support of the adjoining premises—a kind of knowledge that cannot always be brought home with any direct evidence."

This is evidently a point difficult to establish. Houses in streets have very often been built together (afterwards falling under different ownership), and each most probably requires to some extent the mutual support of another, and in such a case the owner of a house has a right to look for support to his neighbor, as the possessors have in law a presumed reservation and grant, even although the original owner parts with some of the houses. The frequent need for taking down internal cross-walls, which perform the office of struts, and for excavating to a greater depth for drains and other purposes than the foundation of adjoining premises, underpinning operations and the like, call for special consideration on the part of architects, that they do not weight builders with undue responsibilities. We can hardly take an extended walk in portions of New York where excavations are being made, or foundations laid, without meeting with instances of sheer recklessness. We must allow that house owners of New York, and it is true probably of those of other cities, are not very forward to assert their rights. They take quietly cracks, and possibly serious settlements, have their doors thrown out of square, and windows fixed without protest, though decisions at law have shown that the building owner is liable. If the latter excavates below a neighboring foundation, he is bound to underpin it, for the first to build and take up his lease is entitled to the support of the adjoining land.

Many buildings are erected depending on lateral pressure, and the law provides a remedy if such support is withdrawn. It is the business of the architect to find out the position of adjoining parties. A landlord owner is responsible for damages to adjoining parties in taking down buildings and walls, the neighboring building being entitled to the amount of support that previously existed, if this support be essential to solidity. There are a great many ways in which property may be interfered with, and the cases in which these have been made the subjects of lawsuits are widely

scattered. The circumstances cited, however, so greatly vary, that it would answer no purpose to specialize them. It may be remarked, generally, that owners of buildings have more rights than, as a general rule, they have chosen to avail themselves of; but this forbearance, viewed from a moral standpoint, should constitute an additional incentive to architects to avoid negligence, and to builders to make the necessary provision against the consequences likely to arise from want of precautionary works.—*Building.*

Our Mammoth Supplement.

TO EASTERN ADVERTISERS.

OUR space is all taken with the exception of a few business cards. These we can readily fill. Do not send any more ads, as we go to print the latter end of this month.

We will do better than our promises made in last issue, as we positively print

52,500 COPIES.

In a short time Supplement No. 3 will be issued, and we will guarantee an issue of

ONE HUNDRED THOUSAND COPIES.

It would be well for our Eastern friends to communicate with us in regard to terms immediately, as we will have no trouble whatever in filling up our space. Remember: FIRST APPLICANTS SECURE CHOICEST SPACES.

Wood Finish.

THE patented preparations known as wood fillers are prepared in different colors for the purpose of preparing the surface of wood previous to the varnishing. They fill up the pores of the wood, rendering the surface hard and smooth. For polishing mahogany, walnut, etc., the following is recommended: Dissolve beeswax by heat in spirits of turpentine until the mixture becomes viscid; then apply by a clean cloth, and rub thoroughly with a flannel or cloth. A common mode of polishing mahogany is by rubbing it first with linseed oil, and then holding trimmings or shavings of the same material against the work in the lathe. Glass paper followed by rubbing also gives a good luster. There are various means of toning or darkening woods for decorative effect. Logwood, lime, brown soft soap, dyed oil, sulphate of iron, nitrate of silver exposed to the sun's rays, carbonate of soda, bichromate and permanganate of potash, and other alkaline preparations are used for darkening the wood; the last three are specially recommended. The solution is applied by dissolving one ounce of the alkali in two gills of boiling water, diluted to the required tone. The surface is saturated with a sponge or flannel, and immediately dried with soft rags. The carbonate is used for dark woods. Oil tinged with rose madder may be applied to hard woods like birch, and a red oil is prepared from soaked alkanet root in linseed oil. The grain of yellow pine can be brought out by two or three coats of Japan much diluted with turpentine, and afterward oiled and rubbed. To give mahogany the appearance of age, lime water used before oiling is a good plan. In staining wood, the best and most transparent effect is obtained by repeated light coats of the same. For oak stain a strong solution of oxalic acid is employed; for mahogany, dilute nitrous acid. A primary coat or a coat of wood fillers is advantageous. For mahogany stains the following are given: Two oz. of dragon's blood dissolved in one quart of rectified spirits of wine, well shaken; or raw sienna in beer, with burnt sienna to give the required tone; for darker stains boil half a pound of madder and two oz. of logwood chips in one gallon of water, and brush the decoction while hot over the wood. When dry, paint with a solution of 2 oz. of potash in one quart of water. A solution of permanganate of potash forms a rapid and excellent brown stain.—*Mechanics.*

What Shall We Stand Upon?

A FEW years ago the architect, in writing specifications for his houses, had very little difficulty in describing the floors. Any good, smooth lumber that was well seasoned, would lie still, and which would admit of tacks being driven in and pulled out twice a year was all that was required. Now the description of the parquetries, borders, and inlays, the matching, the woods, the grain, the texture, the provision for rugs and hearths and registers, make the planning and description of the floors an important and sometimes a complicated affair. The demand for carpets still continues, but there is undoubtedly an increased use for floors that are intended to be used wholly or partly uncovered. This is partly owing to the caprice of fashion, which at present inclines towards rugs, and partly to a conviction that bare, clean floors are preferable on sanitary grounds. Of the woods that are most available for such floors probably none is used more than southern pine, and if this is of the best quality it is very satisfactory and not expensive. The poorer kinds are liable to splinter, which is a serious fault. Maple, birch, and cherry are admirable for this purpose on account of their fine, smooth, firm grain, and the readiness with which they take on a hard polished surface. Quartered white oak is irreproachable. It is needless to say that for a perfect floor—that is a smooth, hard, and unbroken surface—it is indispensable that the material should be perfectly seasoned and also that the narrower the separate pieces are the less it will be affected by atmospheric changes; the less liable will it be to develop cracks and wrinkles as it grows old. It is also very important that the lining floor to which it is nailed should be of well-seasoned and reliable stock. A poor foundation ruins whatever is laid upon it, and the finest hard wood floor in the world fastened to an unseasoned layer of coarse spruce or hemlock boards will no more keep in place permanently than a brick wall would stand upon a foundation of logs. Even if the lining floor is seasoned when laid it is liable, especially if the boards are wide, to be swollen by the damp weather in summer and shrunk by the steam heat in winter, and each board will carry the separate pieces of the finished floor lying upon it. It is a very common thing to see these wide cracks in the upper floor occurring at regular intervals and indicating the width of the boards below. When the upper floor consists of narrow widths running parallel to the lining, that is at right angles to the joists, the trouble arising from the shrinking and swelling of the under floor can be obviated by laying them diagonally. As it is so common to cover the central part of the floor with a rug of some sort there is no reason why this should be made ornamental; plain, narrow strips of any smooth hard wood being all that is required. Around the edges, where the floor is supposed to be seen, a more or less ornamental border is appropriate, but as a rule the less ornament the better, or rather the less elaborate. The manufactured fancy wood floors are, as a rule, too complicated to be agreeable. They suggest puzzles and a sort of intricate but inartistic mosaic that is, to say the least, misapplied in such a position and of such materials. Wood floors are sometimes made by sawing the blocks of wood in very short pieces and setting them endwise with the grain. Such must be laid with the utmost care, and, unless perfectly seasoned, show to the fullest extent the shrinkage. They are not liable to splinter and would be exceedingly durable, although for ordinary use in a dwelling house a well-finished wooden floor of any of the harder woods, especially covered with rugs, would probably stand the wear of fifteen or twenty generations without essential injury. There are many advantages in laying a border of finished wood around the outside of the room a quarter of an inch thicker than the center part, which is to be fitted with a carpet nailed down in the regular way; and this is likely to be preferred by those who find it inconvenient to use rugs without kicking up the corners, and who are unwilling to give up the familiar and well-established custom of regular carpets.

Among those who devote themselves to discovering sanitary faults in buildings the ordinary construction of floors comes in for a share of their disapproval. It is claimed that the cracks that are sure to appear sooner or later are constantly gathering dust and dirt from sweeping and washing, which falls between the joists, upon the lathing and plastering, and becomes a constantly increasing source of uncleanness and therefore of danger. Whoever has helped to tear down an old house or to cut holes in the floors of those that are of recent date, especially if rats and mice have inhabited the inner chambers, will not need to be told that there is an abundance of uncleanness concealed from sight. Much of this is due to the carelessness of builders who leave rubbish under the floors.—*The Builder.*

ARKANSAS produces seventy different varieties of woods used in the mechanics' arts.

Detail Cottage Architecture. Price $10.00

How It Works in New York.

WHEN the plumbing law went into effect in this city and Brooklyn nearly two years ago, it was everywhere regarded as a most important departure in a novel direction in city administration. The law has now been in effect long enough to indicate its benefits. While it has not been possible to obtain exact statements of the particulars in which to-day plumbing has been improved over what it was three years ago, there is not the least doubt that a great improvement exists. It is now impossible to repeat the gross blunders which were common a few years ago. Plumbers, builders, and architects have all been forced to recognize what is essential to the planning of proper work, and it is probably true, as stated by the Health Department, that the law has gradually raised and is still raising the standard of workmanship in the great mass of houses of moderate cost.

Before this law the Health Department had practically no supervision of new work. As a result, in consequence of the fact that the great majority of houses were then, as now, built for speculation by unscrupulous men, serious sanitary defects were very common. Soil and waste pipes were not usually extended above the highest fixture; fixture traps were unventilated; joints were frequently made with putty or cement and very defective; water-closets were flushed directly from the mains; house drains were generally of earthenware, laid under the cellar floor, and often very defective; and many other practices, fraught with danger to the health of the occupants, were common.

The work of enforcing the law was at first attended with great difficulty; owners failed to submit plans and specifications, and builders failed to comply with them after they had been approved by the Board of Health. It was hard to change the prejudices of plumbers, and to make many of them see the necessity for the regulations of the Board of Health. For a time the character of the work continued nearly as bad as before the law, and it was not until the Board resorted to legal measures, and the builders began to see that the law was to be rigorously enforced, that the work showed much improvement. The successful suit of the Board in the case of the Weiher houses at Fourth Avenue and 120th Street did more perhaps to bring about a decided change for the better than any other. This was an unusually persistent and serious case of violation, in which the Board ordered the plumbing taken out and reconstructed and were sustained by the courts.

At last builders have come to see that it is for their interest to have their buildings plumbed well; they have found that it is difficult to sell or rent a building in which the plumbing had not been approved by the Board of Health. It is now a common thing for intending purchasers and money-lenders to go to the Health Department to inquire if the plumbing of the houses they think of buying or lending money on has been approved by the Board.

Notwithstanding the great improvement in the character of the work, the number and occasionally very serious nature of the violations show the necessity for constant vigilance. During the first half of this year violations were reported in 535 houses. This by no means represents all the actual violations, for in very many cases it is only necessary for the inspector to call the attention of the plumber to the fault to have it promptly removed. On the 9th inst. there were reported in progress of construction 2,243 buildings, of which 1,023 contained plumbing on that date. The seven inspectors visit all of the latter at least once a week to inspect the work done since their last visit, and keep watch of the remainder to learn when the plumbing begins.

In justice to the plumbers of this city, it should be said that the great majority of violations are by a few men (not more than ten or twelve), who are outcasts from the trade, not members of the Master Plumbers' Society, or if members not attendants at the meetings. To the co-operation of all respectable plumbers is the success of the law very largely due.—*The Sanitary Engineer.*

How Screws Are Threaded.

SCREW threads are "originated" in the lathe usually. All lathe turning, with regular—constant—feed of the turning tool, is screw cutting, or threading; the tool cuts a spiral around a revolving cylinder.

It is evident, therefore, that by increasing the speed of the feed relative to that of the revolving cylinder, and having the point of the cutter properly shaped, a screw thread would result, instead of a paring off of the entire surface of the cylinder. All important actuating or working screws, as those for feeding on machine tools, are formed in this way, and large numbers, also, of ordinary machine screws, which when once seated are expected to remain *in situ* until the machine or implement of which they form a part is worn out.

Wood screws, as screws for fastening wood to wood, metal to wood, etc., are threaded in a similar manner, the thread being cut from the solid by a single cutter removing the material between the threads.

Large numbers of screws are threaded by dies, which may be called hollow screws, or nuts with cutting edges. These, by rotating, form the feed as well as the cutting device for threading the smooth cylindrical rod or bar. Some of these dies are worked by hand, others by power, but in either case the cut, by the modern and improved dies, is clean, and the thread is formed from the solid. The old-fashioned dies were adjustable so as to be "set up," and could be made to cut several sizes of diameters. Much of their work was done by pressure, or squeezing, and a part of the thread was "raised" instead of being cut from the solid material. There are adjustable dies made now, but they are so formed as to do solid cutting.

There is another method of cutting threads direct from the solid, and that is by milling. It is the invention of the late Eli Horton, the chuck man of Windsor Locks, Conn. The machine is entirely automatic, the blank to be cut being rotated as in a lathe, and a rotary milling tool rotating against it at an angle adapted to the pitch of the thread desired. As the blank revolves slowly toward the cutter, the cutter revolving more rapidly forms the thread by being fed along over the blank as is the cutting tool in a lathe. The milling tool is so formed in cross section as to produce any shape of thread desired. This method is still in use by the successors of Mr. Horton to thread the steel screws of their chucks.

Threads on large cast iron screws are sometimes formed simply by being cast, and formerly there was much cheap small work of that sort in the market.

Threads may be raised by forging in dies, and some good work by this is produced. In both these cases, however, an after finish in the lathe is desirable.

For some peculiar purposes threads are formed by twisting a square or a flat bar, a common form of hand drill that has superseded the bow drill being a case in point. The stock of this drill is a bar, square in cross section, twisted, and which is rotated by sliding a loosely fitting nut rapidly back and forth over its length. A familiar instance of a screw thread of this description is the ordinary auger or bit, the cross section of which is a flattened parallelogram like a flat bar.

One peculiar method of forming screw threads remains to be mentioned. It is that of raising a thread by rolling between dies under pressure. There is a great deal of what is known as "bright wire goods" in the market, which are threaded. In many cases these threads are formed by simply rolling—one revolution, or a little more—the wire between two hardened steel plates that are corrugated spirally to form, when combined, a continuous thread. Sufficient pressure is applied during the rolling—which, however, is very rapid—to raise the metal enough from the annealed wire to make a thread. In this case the threaded portion is considerably larger than the stock or wire, at least half the depth of the thread on each side.

The threads in nuts are produced either by the "originating" method, cutting them in a lathe, by being tapped, or sometimes by being cast of soft metal, as brass, on a threaded core of hard metal, as iron or steel. But nuts are mostly threaded by tapping, running one, two, or three successive taps through them either by hand or in a power machine. Nuts of very thin material, as sheet brass for lamp tops, jar covers, etc., are formed simply by rolling between spirally corrugated rolls, a work analogous to "beading" on tin ware.—*Scientific American.*

Steel Square and its Uses. Price $1.00.

The Influence of Natural Forms on Architecture.

NATURE has not only been the parent of our constructive and decorative art, but has fixed the sites for our ancient cities and highways. She pointed out a commanding site for a fortress or castle to defend the surrounding district. Man has taken the most easy and accessible path from the valley to arrive at the elevation. In course of time dwellings were erected on the sides of those paths, which thus became the ancient highways. And again the spiritual advisers of our forefathers would look around on Nature for a spot suitable for devotion in some lovely valley or charming elevation, surrounded with all nature's bounties, and there erect our ancient building for devotion and education, and thus form another center. Also the majestic river or sheltered spot on our coast has pointed out a site for the dwellings of men suited for their labor and enterprise: thus another center. The more we study nature the more we see her influence. She is not contracted, but casts abroad her gifts for those who seek for them. Her great principles must stand for all ages. The way we clothe them is only the fashion of the hou , so let us respect the thoughts of others and have reverence for the works of our forefathers.

There is one of nature's laws that we are very careless about, the neglect of which is causing the destruction of our stone buildings. Nature forms the stone in beds; we reverse this and make the bed the exposed face. The weather acting upon this affects the face and its bed shell off. Nature speaks very loudly to us in the appearance of our buildings. I trust we will listen to her, give attention, and stay this destruction. There is a bright future in store. Our nation is having a higher art education, and our art-workers are a more cultured people. Rapid strides have been made during the last twenty-five years. Our street architecture is more varied in design, with honest construction and decorative tone. One of our greatest living authors and art thinkers has said (I refer to Mr. Ruskin), "Do honest work, let her principles be seen. If you wish for grace and form go to the grasses, watch the opening bud and developing flower. There is nothing in life, so there is nothing in lifelessness, that has not a les on for you to study." This is the source from which we realize pleasure in the works that have come down to us from what are called the Dark Ages. Would to Heaven we had some of their workers amongst us in this nineteenth century to stimulate us with their devotion and love for the art! It is with loving devotion that we discover her charms, examine her details, and understand her laws, thus bringing us into close sympathy with her; which, if we can realize and portray, is the secret of our art. It speaks to humanity, cheers her in desponding moments, and elevates the thoughts; no discordant sound is heard; all is beautiful and in harmony. If it influences us in our art it will help us in our con act with man to look with a smile of sympathy on his efforts, and not with a frown of discord. We all love sympathy; it cheers us in the anxious hours of toil, and leads us to lift our souls in gratitude to the loving Hand that gave us these glorious works and endowed us with reason to analyze them.

Whatever may be our differences of opinion as to construction or decoration, I think we all try to do our utmost, so that buildings intrusted to us will speak with joyous language to a passing world, and be of such stability that when England as a nation shall not be known, when her banner as mistress of the seas is given to another, her colonies have released themselves from her grasp, and England shall be known only as a name belonging to the past, her buildings of the nineteenth century will be standing, models of the admiration of the now infant empires, and cause them to love and honor the name of Britain. But long may she continue in power, and use it with wisdom for the benefit of the civilized and uncivilized world. W. GLOVER.

Do Away with Air Shafts.

IT was well enough, perhaps, for the examiner of buildings to testify at the Cambridge flat inquest that "the air shafts should have been constructed of brick, with iron shutters over the openings." It was well enough, perhaps, for the coroner's jury to recommend "that all air wells should be lined with brick or metal, thereby rendering them fire-proof." So long as air shafts are tolerated they could hardly recommend less. But why have air shafts at all? The builder of those very Cambridge flats has declared that he would never erect another tenement house excepting on a corner, because he would have to put air shafts in. Many another builder will say the same thing. It will take a little more ground and more brick to build a large tenement with narrow courts running into it, but such a building is sure to be better aired and lighted and safer from fire. To construct a brick air shaft, with iron shutters over the openings, is to largely deprive the shaft of its usefulness, and to suppose that those shutters can be left open ordinarily and closed in case of a fire is demanding too much of human nature in a time of excitement. Let the Legislature do away with air shafts altogether and require in the building law that courts shall be constructed in their stead. The Committee of Architects and Builders have learned by experience that air shafts are far more detrimental to safety than they are beneficial to health, and indeed it is questionable if they are at all beneficial to health in the long run. The committee say unreservedly that the law should insist upon courts opening directly to the air. Whatever else in the building law they may except to from their interested standpoint, we are bound to say that in this we agree with them.—*Ex.*

American House Carpenter. Price $5.00.
Cutting Tools. Price $2.00.
Grimshaw on Saws. Price $4.00.
Mechanics' Geometry. Price $5.00.

The Air of Houses.

THERE is much confusion in the minds of some people, says the *Building News* (London), with respect to the dryness or dampness of houses. An air-tight room is more or less damp, though people are generally apt to think it otherwise if there is no draught, and all the air is carefully shut out. As a general rule, we invariably find the most draughty house is the driest, as it will be generally found to be the healthiest, if not the most comfortable, in cold weather. But the air of a room, as that for an invalid, may become too dry; it may be overheated by a stove, which would become injurious to the patient. In certain cases vaporizers are now employed to give the air of the sick chamber its healthful proportion of moisture.

Mr. G. J. Symons, in a paper on meteorology, has remarked that the subject of the hygrometry of the sick room was unknown two generations ago. If, in addition to temperature, the quantity of moisture in a sick room were indicated by the hygrometer, a great deal more might be done for the invalid's comfort. It is just as easy to regulate the hygrometric condition of the sick room as its temperature, and, in many respiratory complaints, the former is even of greater importance than the latter. The hotter the air is the more water can it contain, and this condition does not appear to be apprehended by those who dwell in such rooms, or provide the means of heating and ventilating them.

Professor Tyndall found that the moisture in the air of an ordinary room absorbs fifty to seventy times as much of the radiant heat as the air does. Moisture is the regulator and conservator of the heat, and in due quantity acts like a blanket, by protecting us from a too sudden cooling or heating. The question is one, we think, worthy more attention by the sanitary builder than has been given to it. Complaints are loud against certain hot-air furnaces, as they overheat the air and render it unfit for breathing; they tend to scorch and dry the air, and to this extent they are unhealthy.

The Bulletin's Report Correct.

THE report of building improvements in San Francisco and elsewhere, appearing in the *Bulletin's* issue of July 20th, was correct, and could not have been otherwise, as the items given were taken from the columns of this journal. The withholding of proper credit in that connection is not to be wondered at, as our contemporary has a chronic ailment in that direction, and we can afford to assist it in providing matter for its readers by furnishing building intelligence for its columns.

Important to those Receiving this Journal.

Should this Journal be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

Locks and Keys.

THE inventive Chinese had almost constructed a Bramah lock, when Egypt herself was young, and the keys found in our tumuli and tombs show how much ingenuity was expended in the construction of these supposed safeguards in all ages. The rude savage was contented, in all probability, with a combination of knots, and, indeed, Captain Galton, in his "Art of Travel," laments the want of some form of knot which would, whilst holding tight the stores, show whether they had been tampered with or not,—thus asking for a Chubb's detector lock of sinew or string in the bush or the desert; but such a series of knots does exist, and possibly a native guide or attendant would fail to untie the famous knot which so puzzles ingenious monkeys. Alexander found it easier to cut than untie the famous Gordian knot, and many primitive locks in use, even in the British Isles, depend on a combination of string and wood, which suffice to keep out cattle if not burglars. It is to guard against the latter that modern ingenuity has been so freely expended, and it would appear really as if the latest Yale lock was only a modification of the well-known Egyptian model of some thousand years ago, and there are in existence examples of locks on the Egyptian model which have survived, and are found to answer their purpose even at the present time, and it has been suggested that with a slight modification this could be used with advantage to "lock" pictures on gallery walls, so that they could be removed in case of fire easily and rapidly. This lock was obviously invented to secure a bar of some size, and has since been used on a much smaller scale.

Some of the earliest and most perfect specimens of locks which have come down to us are padlocks and fetter-locks, some, apparently, only adapted to fasten the girdle of a lady, whilst others are ponderous enough for the heaviest chest. Examples of these are in every museum of importance. It is well known that Bramah believed his famous lock to be unpickable, because he could not pick it himself, and this has been the case with other inventors, though, perhaps, the triumph of Hobbes in 1851 in proving that the champion lock was pickable excited the most attention; but we shall not, in our desire for small keys, imitate the lock which required a species of sickle to open it, for this key has to be carried over the shoulder like the Egyptian keys which are mentioned in Isaiah and figured in the great temple of Karnac; it is in use at the present day. These sickleike keys could only be used to move a bolt on a large gate, and when, as in many modern instances, the bar was hung in an iron frame and suspended in the center by a chain, a smaller key was required to open it, and thus gave rise to those ring keys described by Tacitus, and which answered the purpose of a signet ring as well as a key. Many of the wards of these Roman keys are so much like the ordinary flat or French latch-key in common use a generation ago as to suggest a doubt as to their antiquity. The curious implements found in Anglo-Saxon graves, and which are supposed to be keys from their being fastened together by a ring and slung at the girdle, are, as a rule, but rude pieces of bronze without a pretense to the formation of a ward, and in this particular only do they resemble the keys of the Yale locks of to-day. They could only be used to raise the rudest form of latch.

Amongst the locks which seem to have been most popular, and which are indeed the most curious, are what are known as "puzzle locks." They are found in the shape of a bird, as in India. They are hidden in the interlaced bolt-and-belt ornamentation of an Elizabethan linen-chest, or in the form of a "letter-lock" and then they are independent of a key. The former depend on a secret spring moving the escutcheon; the latter, on a certain combination of words, which require to be remembered accurately by the person using the lock or it becomes useless to him. Some of the more modern letter-locks are very ingenious,—in fact, more ingenious than secure. A couple of centuries ago they were far more popular than they are now, and in the time of our grandfathers, and even later, these secret springs and hidden mechanism were freely used by the novelists of the Mrs. Radcliffe school. They are immortalized in Beaumont and Fletcher's play of the "Noble Gentleman," where we find,—

> "A cap case for your linen and your plate,
> With a strange lock that opens with AMEN."

It is a somewhat singular circumstance that the best of our modern safes have locks which closely follow the secret apparatus described by the Marquis of Worcester in his "Cen ury of Inventions." He describes a little key, not weighing more than a shilling, which shall be capable and strong enough to bolt and unbolt "round about a great chest, an hundred bolts, through fifty staples, two in each, with a direct contrary motion, and as many more from both sides and ends, and at the same time shall fasten it to the place beyond man's natural strength to take it away." He also describes a curious escutcheon, and it was for the invention of a "secret apparatus" of this kind that the Society of Arts awarded one of their first premiums to Mr. Marshall, shortly after the commencement of their transactions, in 1784.

That there were warded keys and locks from Roman times is indisputable, and they were excellently made by the early English metal-workers. No one suspected their weakness until a century ago, and then their unreliability was proved by the easiness with which they were picked by the simplest novice in house-breaking. In vain were back-springs invented, and French tumbler locks introduced. A simple piece of twisted steel sufficed to open them all. The pondrous wooden and iron contrivances which had been trusted as locks should be trusted if they are reliable, were found to be of little worth. The tumbler locks of Barron and of Bramah, patented as far back as 1778 and 1784 respectively, head a long list of inventors of many tumbler and wheel locks There have been locks with master keys invented, and changeable key-locks invented for doors of safes, and other receptacles for valuables. Many of the latter are nearly perfect specimens of simplicity and security, with keys which, if not so light as those mentioned by the Marquis of Worcester, are at least sufficiently portable to be carried in the waistcoat pocket. There are specimens of many of these ancient locks in South Kensington, and in the British Museum, with keys remarkable for beauty of design as well as workmanship, showing, if another instance were needed, how well beauty can be combined with utility.—*The Builder.*

Modern Carpenter's Companion. Price $1.25

"RIGHT-HANDEDNESS" extends very far along the animal series. Parrots hold their food by preference in the right foot, and, though we cannot speak positively, wasps, beetles, and spiders seem to use the right anterior foot most commonly.

Cottages and Villas. Price $6.00.
Practical Carpentry. Price $1.00.

The California Architect and Building News.

VOLUME IV. NUMBER 9. | SAN FRANCISCO, SEPTEMBER, 1883. | $2.00 per Annum, in Advance. Single Copies, 20 Cents.

THE

California Architect

AND

BUILDING NEWS,

Published on the 15th of each month.

BY THE

San Francisco Architectural Publishing Co.

JAMES E. WOLFE, GEO. H WOLFE,
EDITORS AND MANAGERS.

Rooms 11, 12, 13, No. 240 Montgomery Street.

TERMS:

PER ANNUM $2.00 IN ADVANCE.

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, per square, each insertion	$ 2 50
Back " " " " "	2 00
Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.
NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is ¾ of an inch in length by width of the column.

When money is sent for subscriptions, the receipt of a copy of this Journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

SPECIAL NOTICE TO SUBSCRIBERS.

It is our intention, in the future, to have all new subscriptions begin either with the January or July numbers. In order to have a uniform time with subscribers now on our books, credit will be given to those whose subscriptions fall due between this issue and the 1st of January, with the intervening months, so that by sending $2.00 NOW, you will receive a full receipt for 1884. All new subscribers will receive the balance of this year free.

S. F. Chapter American Institute of Architects.

THE Chapter met in annual session on the evening of the 7th inst., President John Wright presiding. The profession of the coast was well represented. The regular order of business was suspended for the purpose of receiving a delegation from the Plumbers' Association, who were present in the capacity of an authorized committee, to discuss before the Chapter the rules and regulations adopted by the Board of Health under the plumbing law of the State, which went into effect August 1st. A Committee of Conference from the Chapter was asked for, to meet a like committee from the Plumbers' Association, to take the whole subject-matter into consideration and prepare recommendations to present to the Board of Health, amendatory of the present rules, which in several particulars do not meet with general approval, and which may be made more practical, and lessen the cost of plumbing work. The range of discussion before the Chapter reached the many points of objection to the rules, and it is believed that a committee of architects and plumbers will be able to harmonize all discordances and provide rules which, if adopted by the Board of Health, will ensure the efficient working of the plumbing law as passed by the last legislature of California. After the withdrawal of the visiting plumbers the Chapter further considered the matter, and appointed a committee of three, consisting of James E. Wolfe, Wm. Curlett, and B. E. Henricksen.

Committee on Seal of the Chapter reported that the matter had been placed in the hands of the class-teachers established by this Chapter.

Reports were then read from those having charge of the classes, and the different officers.

The Secretary reported a total membership of forty-two. The Chapter was fully equipped with a fine set of books, by-laws, etc., and had money in its treasury, with not a single liability.

N. L. Mayo was appointed collector for the ensuing term.

Propositions were read from Masters Lee and Bugbee, each to become student members.

Election of officers being next in order, the following gentlemen were elected:—

President, John Wright.

Vice-President, William Curlett.

Secretary, George H. Wolfe.

Treasurer, H. C. Macy.

Executive Committee, Seth Babson, Thos. J. Welsh, Geo. H. Sanders.

Election of Trustees postponed until next regular meeting.

A vote of thanks was unanimously tendered to F. Marion Wells, Geo. H. Sanders and Albert Pissis, teachers of the various classes established by this Chapter, for their kind attention given to the pupils under their charge.

Adjourned.

Review of Building Operations.

THIRD QUARTER OF 1883—AN INCREASE OF NEARLY $2,000,000 OVER SAME TIME IN 1882.

BUILDING operations all over the coast still continue brisk, and from advices received, the coming winter will exceed in the number and value of new buildings erected, that of any similar period in the history of the State.

The following summary will convey a clear idea of the amount of work that has been done so far this year, and the good showing made in comparison with 1882.

During the first nine months of 1882 there were erected

582 BUILDINGS OF THE VALUE OF $2,655,726.

Same period of 1883 there were erected

635 BUILDINGS OF THE VALUE OF $4,579,878,

thus showing a gain of $1,924,152. We have included in the above the new building at present under way for one of our largest hardware dealers, which is not reported in our Building Intelligence, the contracts as yet not all being let.

The above is a remarkably good showing, when it is taken into consideration, that during the year there have been but three buildings erected costing over $100,000 each. Most of the buildings are private residences and flats, averaging about $7,000 each.

We do not agree with our contemporaries that the height of the building boom has been reached; that "flats" will soon be a drug on the market, etc. The general good times in every branch of business is taken advantage of by many of our good housewives, and they are moving from the "filled ground" quarters to where they can obtain plenty of sun and fresh air, with but a nominal increase of rent.

The cable roads are gradually but surely causing a return tide from the pleasant dwelling places across the bay; and when the Mission Line shall have carried out their contemplated QUICK PASSAGE SCHEME, thus giving the residents of the large valley beyond Thirtieth Street the means to go back and forth on quick time, to almost every part of the city, we have no doubt that the cheap lands in the valley named will soon be filled up with many of those who travel back and forth across the water, for the sake of saving a few dollars by cheaper rents.

New York Street Architecture.

BY A. CURTIS BOND.

THE RENAISSANCE.

THE house shown in our illustration is that of Charles Volkmar, at Tremont, this city. It is strictly French in its construction, its appearance, and its surroundings—Parisian thoroughly, and comfortable as it is attractive. The material is brick with an outer stucco, giving it a creamy surface. There is so little to describe, exteriorly, that I must leave it to my readers' perception to picture for themselves, from the representation here shown, the attractions of the spot and the inviting look of the dwelling. If a high concrete wall could be added in the imagination to the place, a wall extending around the four sides and inclosing about an acre of ground, with neat vegetable plots and flower-beds, and a goodly-sized furnace, it will give not only a first-rate idea of the residence, but likewise a capital notion of what a true French country house is—barring the furnace. Mr. Volkmar is an artist, and beyond that does a little pottery baking on his own account, so the furnace was put up by him for this purpose, and is considered quite a novelty in the way of a diversion by his neighbors, but I presume he often makes it a combination of business along with his play.

At the side of the building is a *porte cochese*, through which carriages may drive to an inclosed court yard in the center, just large enough to permit the vehicle turning. To the right of this court is a small reception room, which in a Parisian house would probably be used as the office for the concierge, or porter, and there is also the parlor and back of it the kitchen, while to the left is a billiard room and the stairs leading to the floor above. This enumeration of apartments appears to be that of an extensive house, but it must be remembered that they are all small, and the building itself not over forty feet square.

The entire house is heated by steam from a furnace in the cellar—a small furnace—and in the place of chimneys are ventilating ducts leading to the roof and opening into each room through a fancy ventilator. On the lower floor a gas burner in this ventilating tube or channel is kept burning, thus causing an upward flow of air, and carrying off the vitrated atmosphere of the apartments. This is an effective and an ingenious idea.

Upon the second floor is a large room originally intended, I presume, for another parlor, but converted to the use of a studio by Mr. Volkmar; opening from it is a small room called the library, and opening from its opposite side is the dining-room. The windows of this latter open upon a veranda or balcony, which has been very tastefully and deceptively fitted up with flowers to resemble, or rather personate, a tropical garden. It has been covered with glass, and by the clever arrangement of mirrors the appearance of quite an extensive flower garden is had from an ordinary five-feet piazza. A stair-case beginning at the door of the dining-room leads to the third floor, which is divided in the conventional manner into three bedrooms and a bathroom.

The decoration is very simple, consisting almost exclusively of wood in its natural condition, color, etc., carved sparingly. In truth the house is not an elaborate nor an expensive one, but has the peculiarities of the French dwelling transported to America. . . . One of the most noticeable of the new buildings put up in this city is that of the Manhattan Storage Company, occupying the entire block on Lexington Avenue from Forty-first to Forty-second Streets, and extending half way through to Fourth Avenue. It is a gigantic brick affair simulating a fortress, or more perhaps after the style of the old feudal castles we are accustomed to see in illustrations of medieval times; it is 150 feet tall, and the building proper has the appearance merely of massive walls, two of them being entirely without windows or doors or openings of any description, while the others have merely an entrance for teams and visitors, two heavily barred windows looking into an office and store room, and two other equally well protected at the third story looking into another store room. All the light necessary is obtained from a well or court in the center. The main rooms, of which there are four upon each floor, are each 50x200 feet, and divided into small apartments by iron railings extending from floor to ceiling, permitting a circulation of air—something very desirable—and at the same time keeping out borrowers and those seeking relics or odd bits.

The necessity for a storage house and a good one, has been burdening New Yorkers for a number of years. There is probably no city in the world that claims so large a proportion of restless residents as this very Empire Town. Every one takes a trip to Europe, occasionally at least; the prosperous business man secures state-rooms on the most expensive line, and his whole family go with him, while his anticipated leaving is announced in the papers of the evening previous; the more modest traveler, who has perhaps left the bank very suddenly that afternoon, carefully avoids notoriety, and his name first appears in the *Police News* a week after he sailed. Whether it is the legitimate excursionist who will safely and instructively visit every capital of the continent, or whether it be the gentleman who will extend his trip only to those countries with which we have no extradition treaty, the anticipation rests with one, and the delusion with the other, that each will return to these United States at some day, so the former stores his furniture and chattels, and the latter does also if he has time. Since the burning of Morrel's storage place, about a year ago, there has not been much feeling of security among those who have found it necessary to put their goods away, and this company has taken advantage of this uncertainty, and will probably become rich. . . .

Since A. T. Stewart's death there seems to have been a positive succession of the most inexcusable mistakes made in the conduct of the affairs connected with his estate. It may perhaps be considered as a just return for Stewart's entire disregard for every one else's interests that his business should have been absorbed by another, his property divided among a multitude of strangers, though all reputed to be nearer in relationship than their names would suggest, a relationship not generally recognized by the law nor sanctioned by the Nestors of society. The building occupying the block on Broadway between Chambers and Reade Streets was devoted at one time to Stewart's wholesale business, a business whose imports were said to be $30,000,000 annually, a business unrivaled for many years in the country, and which aside from its foreign trade embraced several mills, cotton, linen, carpet, etc., in our Eastern States. The retail department was further up town, another entire block filled with busy clerks and shopping women, a multitude of cashiers, an army corps of small boys to carry change. Cyrus Field commenced his career as one of these "cash boys;" the firm did its own banking; all checks were made upon itself. If clerks, and bookkeepers, and cashiers, and directors had to be provided with means for sudden European trips, Mr. Stewart thought it was only fair to give the first opportunity to his own assistants. This is about the only instance of consideration for others that he is known to have exhibited. The most of his time, aside from the immediate conduct of his affairs, was occupied in establishing retail stores in small summer resorts or country places, where his competition ruined local dealers and caused innumerable bankrupts. As I said, however, all his property has lost its association with his name, and the wholesale house to which I referred has changed even its appearance, the countenance it bore during its projector's life. It has been torn apart, and dug out, and built up again, and two new stories have been added with the very singular arrangement of having the new floors stop short of the corners, which have not been raised beyond their original height. The open spaces thus left at the corners are finished with an ordinary brown tin roof, of course two stories lower than the main roof, and are absolutely repellant in their contrast with the more or less white and yellow of the marble front and sides. I am assured by the architect that he has no intention of placing towers or belfries or any other architectural eccentricity at these barren points. The building, I might add, is now to be rented in offices.

There is a moral in Stewart's career somewhere if people would only look for it; the world won't smile at a man's memory whenever his name is mentioned unless there has been something powerful mean about his life.

* * * * * * * * *

There is another New York celebrity of whom we have no reason to be proud—no more reason, I was going to say, than of Stewart, though that would be rather a hard thrust at one or the other of them, I hardly know which could take the most exception—at any rate this second character is not a favorite with any "set." He is Edward S. Stokes, a man who committed a murder as cowardly and contemptible as any that has ever occurred in

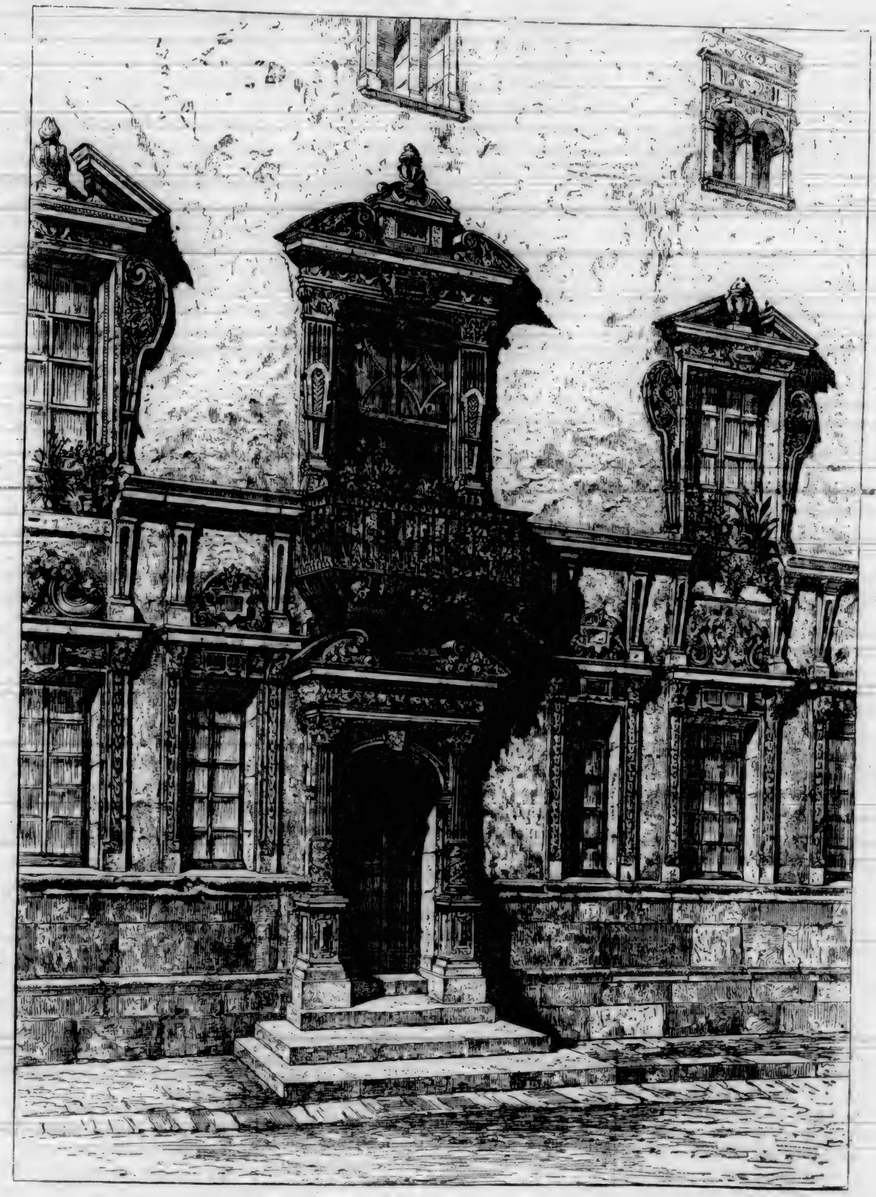

PLATE 1.—ILLUSTRATION OF THE "RENAISSANCE."

this city. Stokes, as you know, served his ridiculously inadequate sentence in Sing Sing, and instead of drowning himself soon as he could after being released, he went into the hotel business here, backed, it is said, by John W. Mackay, and he has made a palace from what at one time was almost a wreck. The Hoffman House was never one of the sanctified hostelries of our city, not even one of the pleasing to look upon, but under the influence of Mackay's cash and Stokes aesthetic taste it is now one of the most startlingly original resorts to be found. Its *clientele* is principally of a sporting tendency, devoted to the perfection and encouragement of the manly art or versed in the respective merits of individual oarsmen and trotters. Owing to this, probably, the place has made money; the bar-room particularly has been successful with its $10,050 picture of Bourgerean of "Nymhps and Satyr" (well caricatured in a recent *Puck*); its magnificent copy of the inimitable figure of "the Diver," the marble statuette of a female lightly clothed in a mosquito net suit, and her arms extended as in the preparation for a plunge; its "Dream of Faust" one of the most beautiful and most suggestive of modern paintings, —all these attractions have done their part in bringing a trade that has enabled Stokes to build an immense addition to his house. His addition is going up on Twenty-fifth Street, directly in the rear of the main building, facing on Broadway. It is a corrugated-looking affair, nine stories tall, and every other window across the front is in a bow, a series of continuous swells, just large enough to accommodate the window, extends from the ground to the roof, and the wall surface separating these elongated bows is merely sufficient to permit a narrow window being placed therein. The material is Milwaukee brick and terra cotta, and the general appearance is dignified and pretentious. I presume the style might be called a modernized Venetian.

Low Charges for Architectural Services.

WITHIN the past month considerable comment has been indulged in by certain parties because a member of the chapter of architects in this city has consented to render architectural services for less than the charges adopted by all architectural societies—namely, five per cent. on the cost of the whole work. This upon its face appears wrong and inconsistent, and unless relieved by the circumstances of the case, is so in fact. Five per cent. is a right and proper charge, and we regret that it cannot be made a universal rule, as its adoption and observance would do much toward elevating the profession to its proper standing. But there are unprincipled men practicing the profession, who find work mainly by underbidding—offering their services at nominal rates and depending upon the perquisites for fuller compensation. And every time that owners succeed in engaging architects at unremunerative prices they pay dearly in the long run for the false economy practiced.

The facts in the case referred to are these: The names of five architects were proposed before the Board controlling the improvements in contemplation, three of whom were members of the chapter. A vote was taken upon the names submitted, which resulted in the selection of one of the three chapter members. A committee was appointed by the Board to wait upon the selected architects to ascertain what compensation would be demanded. They were plainly told that five per cent. was the right and established price, a copy of the by-laws of the chapter was handed them, in which the scale of rates is printed. To this the reply was made that much lower rates had been offered by other parties before the Board, and that the Board would not consent to pay the five per cent. Knowing that one of the outside party, or firm, had done numerous mean things to secure work, althou h enjoying a large practice, the architects selected stated that they would not *again* permit themselves to be beaten, and would *reluctantly* abate the regular charge, rather than allow the work to pass into hands that cared nothing for professional rules, and who had in many *well-known cases* done extraordinary things to break existing engagements between owners and other architects, to obtain work which would not have been awarded to them except through persistent doggery and strained influences of various kinds.

Beside this, when the scale of charges was adopted by the S. F. chapter,—being the same as those adopted in all chapters and architectural societies throughout the Union, in England, France, Germany, and other European countries,—it was understood that when members of the chapter were placed at a disadvantage through the *unprofessional acts of outside parties*, they should have the right to exercise their own judgment in meeting the issue. This was done in the case in hand, and while the proper rates have been departed from, the price agreed upon is greater than was offered by others in the contest. So that while the chapter member may have technically sinned against the rule, the end has been attained of defeating others who *systematically* scruple at nothing sinful to obtain work.

We repeat, five per cent. is but a right and proper charge for faithful architectural services, and if all men engaged in the profession would adhere to this, owners would as willingly pay the amount, and think better of architects for demanding fair pay, than they do under the too commonly practiced system of a portion of the profession taking work at any price offered, and doing the best they can to "get even"—the latter course tending to degrade and demoralize the profession, and place owners subject to all the circumstances attendant upon conditions of trusts unremunerated. It is an old and true maxim that insufficient compensation stimulates a disregard of strict integrity in any capacity.

Large Sticks of Timber.

HUNDREDS of visiting Knights Templar had an opportunity while in this city of seeing two of the largest pieces of timber that ever passed through the hands of the millmen. It was amusing to hear the remarks, and watch the various changes in the different countenances caused by a survey of probably the finest pieces of timber that were ever sawn. One piece is 144 feet long by 18 inches in size, and contains 3,456 feet of lumber. For over 100 feet there is no knot that a five-cent nickel will not cover, and in the whole piece of timber the largest knot can be covered by a half dollar. It is wonderful that a stick of timber of the size given should be so remarkably clear of knots. Its companion is of the same length, 16 inches square, and contains 2,352 feet. When it is taken into consideration that the tree from which the first mentioned piece of timber was taken was cut several feet above the ground, and that 150 feet from the cut made to fell the tree, it was of such a size as to enable the millman to saw the log so as to produce a piece of timber of the size given, one can imagine the size the butt must be, and partly comprehend the amount of labor required to handle such an immense stick.

It costs about one-half more to land on our wharves a stick of timber of the size mentioned than it does of ordinary lengths.

These pieces of timber were sawn at the Port Blakely Mills, Washington Territory, the owners being Renton, Holmes & Co., the well-known lumber merchants of this city.

A short time ago there was received in this city a stick of timber 104 feet long, 24 inches square, and almost free from knots. After its arrival here it was allowed to be on inspection for a short time, when it was taken to one of our mills and sawed into joists, as the purpose for which it was manufactured was given up and no use could be found at the time for a stick of timber of such large dimensions.

Now Is the Time to Advertise.

IN order to supply the demand for sample copies now constantly being made upon us, we will during the next four months issue ONE THOUSAND EXTRA COPIES EACH MONTH, of this Journal.

The supplement has been, so far, the means by which we have received over 500 orders for sample copies of our Journal, in most cases accompanied by twenty cents, the price per copy of our regular issue. This too when, as yet, not one-half of the supplement has been distributed.

Of the latter we printed, by actual count, 54,880 copies, and its distribution will be general all over the Pacific Coast.

We intend, in the near future, to issue Supplement No. 3, and will guarantee to print and distribute 100,000 copies.

ADVERTISERS WILL PLEASE TAKE NOTICE. The great extra demand for this journal insures your advertisement being seen by many thousands, who would otherwise, probably, never hear of the wares you seek to introduce amongst our people.

Papier Mache Floors.

A NEW style of floor decoration is now becoming desirable from its neatness and great durability. There is no liability of its becoming common from sameness of design, for the materials are of great variety, as is found in wall paper. The process for covering a papier mache floor is as follows: The floor being well nailed the holes and cracks may be filled up flush with Plaster Paris dissolved in thin glue water, leaving them even with the floor, by using a broad bladed knife. The cracks are sometimes filled with soaked papers mixed with paste to the consistency of putty and applied in the same manner. Any good flour paste will answer, and if a little alum is added will prevent the souring tendency of the paste. The floor is then sized with the paste and covered with any cheap paper, and if the flexibility is not considered sufficient, a second application is made, crossing at right angles the course of the first layer. The lower priced wall papers will do for this purpose. After this is thoroughly dry, the pattern of wall paper is cut and laid on in the same manner as upon walls. A wide dark border is then added next the base board, thus inclosing the whole in one pattern. If further decoration is desired, a center piece may be added, as also flower bouquets in the corners. When the paper is dry, a light thin coat of white glue is laid on very quickly, not allowing the brush to pass but once over the colors, for fear of disturbing them. A second coat of size is necessary to make it strong enough for the varnish. In making this size it is usually soaked in cold water for two or three hours and then heat it on the stove or add boiling water, stirring it well to insure a mixture. When the glue sized floor is dry, it is then ready for the varnish. One or more coats of turpentine furniture varnish is applied, or a coat of hard oil-finish varnish is spread over the entire floor, leaving it when dry with a bright glossy surface. The details of this process are to be followed with care, thus insuring a complete success and presenting when finished a durable and cheap papier mache carpet. This new floor covering is suited for small rooms, halls, stairs, and the kitchen even if kept well coated with varnish. This furnishes a floor perfectly water and air tight; it may be washed and scrubbed like other floor covering. To further protect these mache floors where much used an occasional coat of wax that is dissolved in turpentine should be applied either with a brush or rubber made of cloth. The wax leaves the floor smooth and wears glossy and is easily kept clean. J. E. W. C.

A SCOTCHMAN employed to build in London used steam cranes to hoist the bricks up to the required height; and as the English workmen refused to have anything to do with a job where steam supplanted men, workmen had to be brought from Edinburgh to finish the hotel.

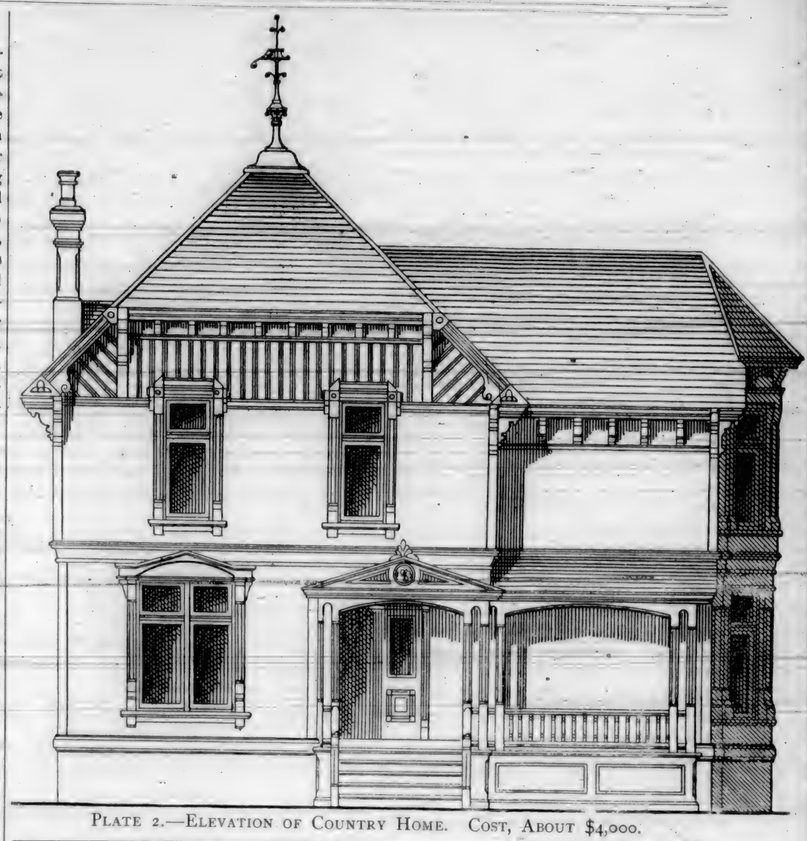

PLATE 2.—ELEVATION OF COUNTRY HOME. COST, ABOUT $4,000.

Concerning Sanitary Science.

"ONE of the marked changes of our time is the altered position of the physician in the community. The traditional duty of the doctor is to cure disease, and disease was supposed to be a sort of malignant entity which had got into the system and could be expelled only by the most energetic and heroic remedies. Physicians were said to belong to the medical profession, as the chief business of the doctor was to prescribe medicines, which were mostly drugs. And Voltaire wittily summarized the work of the physician as an attempt to work a miracle by reconciling intemperance and health. A half century has altered the whole scope of medical study. Sanitary science profoundly affects medical theories. And the upshot of it all is that the old faith in drugs and medicines of all kinds is fast dissolving. People are everywhere learning that sunlight, pure air, good food, a proper dress, regular habits, plenty of sleep,—in short, that right living is a million times better than all the medicines of the world.

The great physicians of our time are vastly more interested in sanitary science and hygiene than in therapeutics. They are studying anew the questions pertaining to life. They are investigating the conditions of perfect physical existence. They are giving lectures, and writing books on the great art of keeping well, of developing physical force, of building up a perfect body. The questions of drainage and ventilation, of the nutritive values of the different kinds of food, and the proper methods of cooking, of artificial exercise when it is necessary to resort to such expedients, the heating of houses, and the quantity and fashion of clothes that should be worn, are assuming an importance hitherto unknown. Everything that relates to the art of living, so as to avoid sickness and pain, and maintain the highest degree of power and enjoyment is invested with new importance. The physician is no longer 'a medicine man;' we send for him when ill, it is true, and value his curative services as highly as ever; but we would pay him a double fee to keep us well. He is a member of a health police, whose function it is to keep people from getting sick, and hold a disease at bay. And instead of killing a doctor when a patient dies, after the manner of the Emperor of China, the skill and proficiency of the physician of the future will be determined by his success in keeping his patients strong and well; and should they fall ill, he may be dismissed for a better one."—*Ex*

Important Facts in Regard to the Great Pyramid.

In our June number, 1883, we presented to our readers a diagram of the supposed manner in which the Great Pyramid was built, with an explanation of many important facts in regard to its history, and the wonderful results deduced from the measurement of its different parts.

Since that issue we have received many letters asking for explanations in regard to problems suggested by various thoughts of different readers. In order to answer such queries we present a few items in regard to the wonders of the Great Pyramid. Our readers will bear in mind that the thoughts contained in the succeeding paragraphs are but those culled from the works of those who have made the "Grand Mystery" a life study.

"*If the Great Pyramid is over* 4,000 *years old, how is it that the stones of which it is composed do not show the same signs of disintegration that are noticed in ruins of a much more modern date?*"

To answer this question we must first ask, What are the causes, natural or otherwise, that tend to decompose solid rocks? The most powerful elements are frost and rain. In parts of our own country we often have occasion to notice the mighty power of water that has been confined in clefts and seams of rocks, suddenly expanding by being frozen, and with mighty power rending rocks asunder, and at times tearing away the whole face of cliffs. In Egypt the climate is dry and sultry, and so slight is the pure decay which takes place in earthy matter that even crude or unbaked bricks, formed merely of Nile mud, have been known to last some 3,000 years; and stone blocks, of which Egypt has vast supplies and of excellent quality, have lasted longer still. So we see that frost, the greatest enemy perhaps of stone, is a minus quantity in the land of Egypt.

The Pyramid is situated in a desert of sand. How, then, can it be founded on a rock?

It *is* built on a rock, and one specially leveled for the purpose. The four corner-stones are let into the main rock, and the four sides of the building face exactly the four cardinal points of the compass.

In building such an immense pile of masonry, the chippings practically would amount to thousands of tons. No trace of these fragments is left. What became of them?

The Pyramid is built upon a rocky hill and much of the material used was excavated therefrom. Some writers speak of the Pyramid as being built upon two hills, the surface of which was artificially leveled. One-half of the northern section or hill has been shown to be of pyramid chips. This fact was proven by the action of nature's elements. In Egypt sudden torrents occur that sometimes make a mighty change in the face of nature. They caused channels to be cut in the vast piles of sand and chips, sometimes to the depth of sixty to seventy feet, exposing to view the chips that were trimmed off from the stones. Near the top of the heap are chips of black and white diorite, much the same as the statue of Shafre, in Boolak. No such material is seen in any tomb, or in the Pyramid itself, except near the entrance passage. Hence the inference of an undiscovered room in the Pyramid—the muniment room for the monument.

One important fact is interesting. Many of the ruins in Egypt are covered with hieroglyphics. *Why is it that we find no signs of any in or about the Great Pyramid?* This is a question that we would like to have answered by some of our scientific men.

The Great Pyramid is really a most gigantic proof that that eventful beginning of stone architecture, by the highest and best-built structure that has ever yet been erected, shows that Divine Inspiration must have energized its builders. The material of which the Great Pyramid is composed would build a wall one foot thick, five feet high, and over 3,000 miles long. It contains more than 80,000,000 cubic feet.

Remarkable Invitation.

We have been favored with a copy of one of the most remarkable "invitations to architects" which has yet come under our notice, and take a certain satisfaction in giving it currency. The building to which the attention of the profession is directed is intended for the use of a cotton exchange, and the competitors are required to furnish plans, elevations, sections, diagrams of construction, full and accurate descriptions, and "full detailed bona-fide estimates" of the cost of construction of their designs. The circulars have no date, but unless our invitation was unduly belated we are forced to conclude that the competitors generally are expected to go through with the labors specified in about thirty days. This, as we need not tell those who know anything of office business, would involve very lively work on the part of an architect and his assistants, and one would suppose that a committee in such a hurry would expect to pay liberally for compliance with their wishes; so that it is with some surprise that we read a sentence near the end of the circular, announcing that "no premium is offered to competitors," and a careful search through the whole document fails to reveal any promise or suggestion whatever that those who accept this extraordinary invitation will be regarded or treated otherwise than as simple gudgeons, who do not know enough to see whether there is any bait on the hook before biting at it.

An experienced eye will be caught by another curious circumstance in the wording of the circular. In mentioning the details of the accommodation required in the building, the sizes of the rooms to be provided for are specified with a startling exactness. We read, for instance, that the basement "is to contain a restaurant of about thirty-nine by sixty-five feet, with a room which may be used for kitchen or office; an office which may be either adapted for banking or insurance business, of about twenty-six by sixty-six feet; an office of about twenty-six by thirty-nine feet," and so on; while the story above is parcelled out with similar minuteness. By applying to these peculiar features of the invitation that Socratic questioning which is so dear to the mind no longer subject to the illusions of youth, we may perhaps convey a useful lesson to some of our readers. "How does it happen," we should first ask, "that the desirable height, width and breadth of all the principal rooms in the building have fixed themselves with such exactness in the minds of the committee?" "Evidently," we will suppose Alcibiades to answer, "because the dimensions were measured from some plan." "But if the committee has a plan already made which it thinks well of, why does it send around to architects inviting them to 'compete' in sending more plans?" "Perhaps because it thinks it might be useful to collect the ideas of other people on the subject." "Judging from all the indications, what benefit seems likely to accrue to the innocent persons disposed to exhaust themselves in efforts to furnish these ideas?" We listen in vain for a reply. "What degree of intelligence, then is to be attributed to those persons, if any, not concerned in the drawings which have obviously been already prepared, who may respond to the committee's invitation?" We leave this question for our readers to answer.—*American Architect and Building News.*

Detail Cottage and Constructive Architecture. Price $10.00

The Position of Architects in South America.

A correspondent writes, from Buenos Ayres, that the professional emoluments of architects are by no means large in that part of the world, while their social position is not the same as in Europe. There is no restriction as to any one who has a mind to do so, calling himself an architect, and persons intending to build, after getting the skilled opinion, and even the designs of an architect, sometimes dispense with his services when they have secured his ideas, leaving him without remuneration. The Italian working masons are skillful in copying whatever is placed before them, and this fact is referred to as exercising an injurious effect upon the prospects of architects in South America.

Important to those Receiving this Journal.

Should this Journal be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

School House and Church Architecture. Price $4.00.

Extra Drawings Required by the Plumbing Law.

The rules and regulations adopted by the Board of Health require that plans for the plumbing and pipe work as proposed by architects engaged in the erection of buildings, shall be filed in the office of the Board. This hitherto unrequired regulation has met with some opposition from two causes. First, it imposes extra work upon architects, which all feel should be compensated, and raises the question as to who should pay the bill. The plans and specifications for buildings, as generally understood, do not include this extra work, and it is only fair that it should be paid for by some one; and there can be no other rational conclusion reached than that the party most benefited—the owner—should bear the expense. The intent of the plumbing law, and its practical effects, if strictly enforced, is to protect owners from the many frauds which have become almost universal in plumbing circles, the better classes of plumbers having been forced to avail themselves of many of the tricks practiced by the "tinkers," to enable them to aproximate the "scrubs" in prices. Consequently, perfect plumbing work was the exception, and owners failed to realize that in the intrustment of this important branch into the hands of incompetent men, because they proposed to do the work cheaply, was a very unwise, and, in the long run, a very expensive rule. And as the new law proposes to remedy the evils so long existing, owners should willingly consent to pay its small expense of preparing the extra drawings. The better and squarer way would be for architects to make, and owners to recognize, a separate charge for the extra drawings; but if this cannot be done, then we renew the proposition made in our last issue that the cost of the extra work be paid by the plumber—it being made an item in the plumbing specifications—in effect, the same as the plumber paying the Spring Valley's charges for water connection. The second objection comes from that class of architectural frauds who are ignorant of every finer point in plumbing science, and who could not, if they would, fix up a creditable set of plumbing specifications. Hence they prefer to be let alone and not required to expose their inefficiency and ignorance, preferring to enjoy undisturbed the rational logic by which they perpetuate their impositions, to wit: that those owners who engage them should be permitted, and by force of such engagements compelled to accept the character of work planned by them.

But as the new law is a good one—not perhaps as perfect and thorough as it might be—we hope to see it enforced rigidly, and trust that Mr. Sweeney, the inspector, will press its efficiency to the fullest extent. There should be no mincing of matters, but a determined and persistent effort on the part of the inspector to weed out all the bad things aimed at by the passage of the law.

Steel Square and Its Uses. Price $1.00.

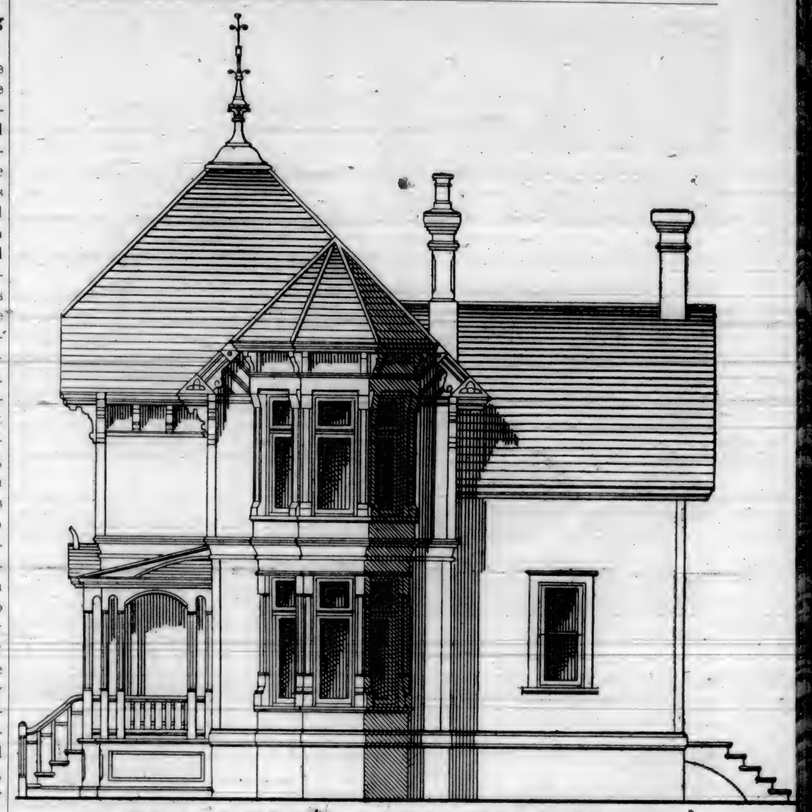

Plate 3.—Side Elevation of $4,000 Country Home.

Balance of the numbers of this year given free to all new subscribers for 1884.

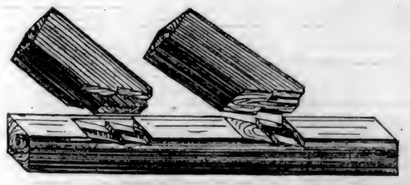
All old subscribers whose time expires between the months of July and January, upon remitting us $2.00, will be credited with the intervening months, so that their subscription may commence with January number.

Cost of Building Materials.

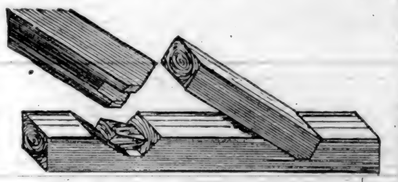
About the first inquiry made by persons contemplating building improvements, is in reference to the cost of materials; and nothing more effectually dampens the ardor of those wishing to build, than to find the material market inflated; and numerous contemplated improvements have from time to time been delayed for a greater or lesser period, or entirely abandonded, owing to the "high price of materials." Every advance in prices, whether in things purchased or in labor, operates as a scarecrow to timid owners, who grow pale at their own shadow when money is to be expended, or the sum of their bank account diminished; while others governed by correct business principles refuse to accede to demands bearing the impress of extortion. When prices exceed seemingly fair and legitimate rates, with no special cause for increase other than the self-evident disposition of the seller to augment existing fair and sufficient profit, extortion looms up in the mind's eye of the buyer, who, rather than submit to the extra tax levied, is apt to institute a wait until the "market regulates itself," and prices settle down to a reasonably fair standard. There are but few men unwilling to pay right value for things obtained, and equally few who are willing to submit to exactions not warranted by rational, business facts, other than avarice on the part of those controlling the manufacture, production, or sale of things desired. Hence the building of houses is to a large extend controlled by those who, when buildings are erected, reap the greater benefits and profits resulting from the construction operations. And material men and workmen would do well, when contemplating acts or purposes calculated to add to the cost of improvements, to consider whether it is the better policy to "kill the goose that lays the golden egg," or to feed the bird and continue it in good health and vigor, and await the regular deposits as they come.

☞Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas, send us a sketch of them and we will make the cuts.

EDITORS ARCHITECT: Will you please give us, in your next issue, examples for framing oblique mortises. We understand that there are new methods being used, and wish to keep up with the times. E. & L., Mission St



The above cut represents two ways in which oblique mortises are framed. They are not new, as we used the same more than a score of years, and they must have been in use more than a score before our time.



This cut shows two methods often employed. Each different one has its own champion. We have yet to learn of anything new in regard to this kind of mortise.

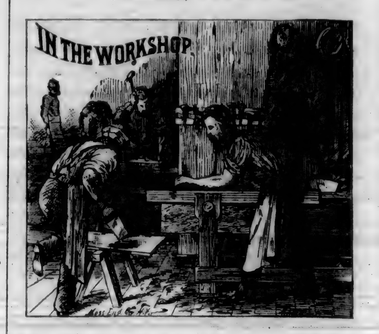
OF INTEREST TO BUSINESS FIRMS.—The Supreme Court of California has decided that a firm cannot obtain judgment till after a full publication of the notice of co-partnership by said firm.

All new subscribers for 1884 will receive the balance of this year free.



We will be pleased to receive for publication in this column items of information in regard to practical ideas connected with the mechanical part of the building trade.

[From "Steel Square and Geometrical Problems."]

To find the angle to mitre an equilateral triangle.—Set off 12 inches on the mitre-box; place the square on the points, with 6 inches on the tongue; mark from the blade for the cut required; and from the tongue for the cut to mitre a hexagon.

To find the angle to mitre a pentagon of five sides.—Place the square on the mitre-box, with 6¼ inches on the tongue and 12 on the blade; mark from the tongue for the cut required.

To find the angle to mitre a heptagon of seven sides.—Place the square on the mitre-box, with 5¾ on the tongue and 12 on the blade; mark from the tongue for the cut required.

To find the angle to mitre an octagon of eight sides.—Same as above, using 7⅛ to 18.

The above cuts are for use in a mitre-box, and should be kept in mind by every mechanic.

THERE are several preparations to keep glue from smelling, but the following directions if followed will be better than any patent arrangements. Cut a piece of zinc the size of the bottom of the vessel in which the glue is boiled, and let it remain in the pot. When you are through using the glue, take the pot out of the one holding the water, so as to let the glue cool off as quickly as possible. Heat it only when needed. Add a few drops of oil of cloves. The best way is to make enough to last two or three days, thus always having it fresh.

Lessons on Hand Railing. Price $5.00.

Stables, Fences, Out Buildings, etc. Price $2.50.

Sample Copies.

Hereafter we will forward no sample copies of this Journal unless the price, twenty cents for each number, accompanies the order.

A MAN breathes about eighteen times a minute, and uses 3,000 cubit feet of air per hour.

Railroads—Their Values.

THEIR INFLUENCE ON THE MECHANIC ARTS.

Do any object to railroads to-day? At first thought it would hardly seem possible that one living in this age, in this generation, in a country like ours, could honestly and seriously find objection to such a convenience and blessing. But there are people in the most enlightened and moral communities that will oppose any scheme whatever—the most labor-saving, the most ameliorating, the most philanthropic, the most beneficent, the most civilizing—no matter whether it brings with it comfort, peace, or joy, there are objections to it.

We have read of a man who had spent a large part of his life in prison, who, when the doors were opened and he was offered his liberty, objected to the condition of things outside. He was not *en rapport* with society or with nature; he needed adjusting; so he left the fresh air and sunshine, the birds and flowers, and went back to his dungeon.

People objected to coal when it was first dug from the earth. It was black; it was dirty; it was not the dry, clean wood of custom. So people objected to coal oil and to gas for similar reasons; they were not the tallow candles of their mothers. They objected to labor-saving machinery when first introduced, and organized riots to throw it out of the windows of factories. It interfered with hand work. The first steamboat excited opposition at once. "It would not go; it would certainly explode; it would doubtless sink." When the Representatives of Congress, who had been induced by months of pleading to vote for means to build a boat, took the first pleasure trip on the Schuylkill River in Fitch's little steamer, they moved at the speed of four miles an hour, and the people on the banks shouted "I told you so!" and the Knickerbockers on the Hudson, in Fulton's first boat, did likewise. That was eighty years ago.

And when the railroad was suggested the croakers were no less; they had not died. It required years of the most persistent effort and crowding to start these new things and make them popular—years of the most patient showing as with children, unwearied talking, unyielding push, push, push.

A Nashville editor once said that that city solicited Congress for aid to build a post-office and a Custom House. A quarter of a century passed before they got either, needful as those things are.

One hundred years ago Watt was dreaming and studying over his tea-kettle. He watched and saw the steam puff and lift the lid and shake the tiny vessel, and the evolution of the steam engine and locomotive began then and there.

Suppose these had not been born in that dream! We, to-day, would still be struggling with the forces of nature as men had been for ages—fighting with earth, and wind, and ocean, with hills and mountains, with deserts, swamps, and forests.

The first known railroad came into being in England in 1833, we think. It was not the road of to-day, by any means, but it was a beginning of the career of a great civilizer.

The first road in our country was a short one in New Jersey, if we mistake not. There was another in Massachusetts, and another in New York, all short, and not far apart in point of time. They were primitive specimens of work, doubtless, and the first cars were drawn by horses, we believe, at a speed not much greater than that of the common road.

The development in these fifty years has been wonderful, but it has been through struggle—stubborn fighting against obstacles without number; struggles with individuals and with combinations of men; with township, county, State, and the United States, in Congress; with poverty and wealth, with ignorance and intelligence, with greed and envy and the selfishness of the dog in the manger.

The sharp practice, the checkmating, the blocking of wheels, the whole conflict of opposition, has been in the face of our own interest—the people—undoubtedly, however honest may have been the objectors in it. It has delayed advance and checked development; but growth has gone on in spite of it. Some earnest soul brooded in secret over the problem until the railway shaped itself in his mind; the purpose was formed, and with bulldog tenacity he clung to his project until he saw a mile of railroad built. Now we have 115,000 miles of good road. The speed on that first road was moderate, but now only the telegraph and the lightning excel it.

Is opposition dead? Have men changed? Project a road to-day anywhere, in any direction, and of any length, across the village or across the continent, and see if human nature has lost all the animal in it. See if the bear and the lion, and the wolf and the lamb (and the pig) will lie down together, and if a little child may lead them? No! Human nature is to-day what it was fifty years ago,—what it was ages ago,—selfish, envious, greedy. It opposes what is not its own. But energy and enterprise thrive by opposition. When a strong soul appears on the stage of action, with a purpose nursed in resolution, courage, and fortitude, opposition only stimulates it; antagonism cannot crush it, cannot drown it, cannot stifle it. Of such spirit is the genius of the nineteenth century. Daring enterprise, tireless energy, unexampled fortitude, and heroic vigor characterize the great movements of this age, and

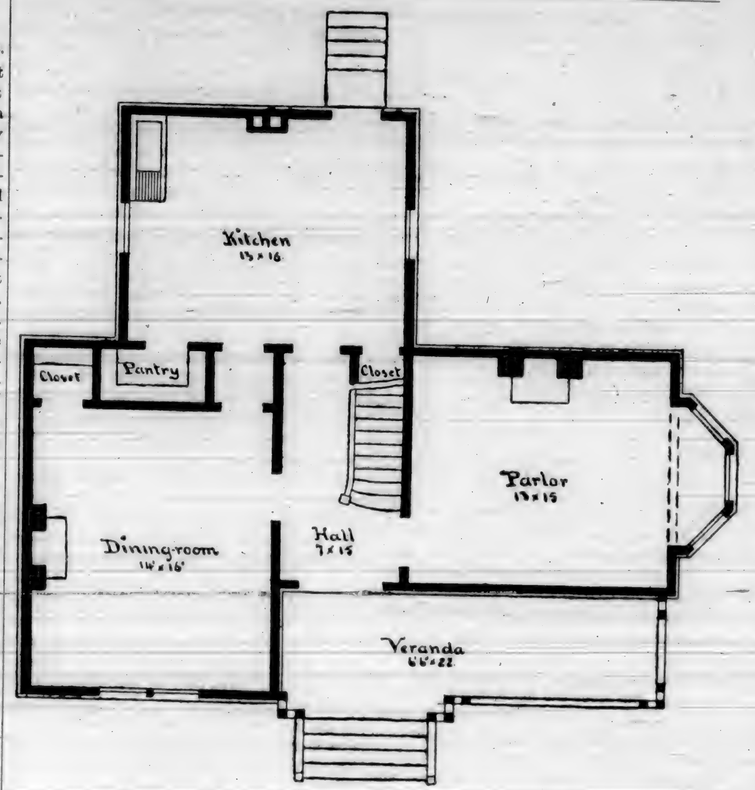


PLATE 4.—FIRST FLOOR PLAN OF $4,000 COUNTRY HOME.

one of the greatest enterprises marking it is the development of the railroad.

What has the railroad done? Beginning as a single short thread, it has grown into a web that covers the whole country east of the Mississippi. It has almost annihilated space and distance, and has brought far places together. It has united the Atlantic seaboard and the great inland valley, which rivers could never do.

It has been said "the highways of nations are the measures of their civilization." These highways may be the ocean, or the rivers, or the valleys, but they must exist in nature or be formed by man. If men are isolated and dwell apart there can be no society, no great Governments, no development of wealth, commerce, manufactures, mechanic's arts, fine arts, letters, or general culture.

Statistics in Europe and this country show that this development is almost in direct ratio to the growth of railroads. Before 1833, when the first railroad was built in England, the exports and imports of that kingdom were at low ebb. In thirty years the increase was £400,000,000, or about fivefold, and this can be shown to be the result of railroad extension.

In our country the development would have occupied ages if colonists had followed the river valleys only, as these are all in one general direction, the system of the sea board and of the Mississippi Valley tending from north to south. No water course cuts the country from east to west. But since the net work of roads has been laid all over the country, population has poured in, and the great commercial centers of Buffalo, Rochester, Cincinnati, Cleveland, Chicago, and St. Louis have been developed, and a hundred other large towns built up.

The 115,000 miles of railroad in the United States have cost about $5,000,000,000, equal to nearly one-tenth of the whole property value of the country, or one-fifth of the capital resulting from labor on the land. They give employment to over one and a half millions of persons, said to be about one-seventh of the whole male adult population. They pay out in wages and material about $500,000,000 yearly, that will help support a large number of families. They move 400,000,000 tons of freight, which will employ many poor men. This freight mainly belongs to laboring classes in common, and not to any privileged class, and therefore it interests those directly.

The relations of railroads to the public are so general, constant, and intimate that it hardly needs any illustration or emphasis. The progress of the whole country is due in a large measure to railroads. The increase of exports alone in the ten years from 1870 to 1880 was nearly $500,000,000, three-fourths of which was due to the great West and the Pacific Coast, and the products were carried East by railroad. Thus the railroad became an agent to establish the balance of trade, and really aided the Government to resume specie payment.

Individuals that dwell apart from their kind, shut out from social life, become peculiar and narrow in their views, habits, and customs; their development is abnormal; they are oddities. So colonists in isolated districts, with no great avenues of communication with outside life, do not become a strong, vigorous, enterprising people. They are not the leaders or powers in the world. Robust, earnest minds, alive with thought will not be shut in. They will make a way out if none exists. Intercourse with people expands the soul, and enlarges our whole nature in all directions. It harmonizes thought and feeling, rubs off the corners and peculiarities of character, and produces similarity in ideas, habits, and customs. New England with its Puritan thought and customs, New York with its Dutch habits, New Jersey and Pennsylvania with their Quaker habits, and Virginia and Maryland with their English adventurer's life needed assimilation—a commingling and a union of common thought, feeling, and interests.

Intercourse promotes peace and good-will better than treaties or the Peace Society; it is a better conqueror than war. If this web of iron roads had been spread over the country a half century earlier, it is believed that the civil war would never have occurred, for when people are moving from one end of a kingdom to the other with such facility as the railroad gives, they tend to become one in thought and feeling. So the North and the South can be united better by railways than by their rivers and valleys; the Atlantic shore with the Mississippi and the lakes, only by railroads, in such union as is now demanded. The great States of the new West, the new Northwest and the new Southwest must be banded together and linked to the older East. How, except by railways?

The eighteen hundred miles of road, completed fifteen years ago, perfected the line across the continent. Along that smooth line many of us have glided in comfort. But have we ever been sufficiently appreciative of the provision thus made by which we can so quickly and comfortably span the great spaces that lie between us and "Home, sweet home" in the far East? Have we ever sufficiently appreciated the thought and the labor that gave us this firm, smooth passage, and the lightning speed day and night, till the dear old spot was reached?

Riding on this peaceful journey, and resting, have we ever dwelt on this topic and tried to go over in detail the planning of this grand highway? In our dream have we also been with those few men in that obscure room, night upon night, week after week, and month after month? Have we heard the story from the beginning, and followed it through its stirring chapters, its lights and its shadows, its hopes and its fears, its promises and its despairing? It is an easy thing to ride and eat, read and sleep comfortably on that road of two thousand miles; but is it an easy thing for a few private business men, without fortune, to build it? Does it require any expenditure of thought and judgment? Is it thrown up on a sandy, level plain—a work that a few men can do in a few days?

Look out on the road as we travel. Moving out of these green California valleys, we begin to climb by easy, almost imperceptible grades, the low foot-hills. We pass over river and stream and the rise grows steeper and steeper. We creep on and up, until we are gliding along on the edge of dizzy cliffs, eight thousand feet above the sea level, and look down into gulfs seemingly fathomless—abysses of darkness. We have come up out of the plains of flowers on to the mountain heights of granite—the snow and the ice all around us. We plunge into the white drifts and our pride suffers and goes down—for, great as is the strength that drives us, we stick fast. We come out at length and go on down upon the cheerless desert. No greenness there—no beauty, no life—nothing but brown sand, whitened with alkali—utter desolation and barrenness everywhere.

All this in the beginning had to be thought of before a shovel was touched, a pick struck, or an axe lifted. One hundred thousand men had built the pyramids, true, but they were slaves, and bent the knee at the edict of the imperial autocrat of Egypt. "Is not this great Babylon that I have builded?" said another dictator. But here was no such power, no Croesus, no Oriental treasury; only four earnest, working men, in a plain room—all the surroundings of republican simplicity.

Newton worked patiently seventeen years on the problem of universal gravitation. This was their problem—to make a pathway across the continent, which would be like an artery bearing a living current from the life of the East to the life of the great West, which should carry and mingle the spirit and culture, the social, civil, and religious life of the East into the West, until there should be but one American life. It was a serious study, demanding much thought, time, and money. It might take seventeen years.

Columbus had grown haggard over such a problem. Looking over the ocean into the sunset, he caught glimpses of a pathway that common men could not see. By that light "that never was on land or sea," he had clear vision of a great highway, over which his soul longed to travel. He studied for years, wandering from court to court, to find means to "go west." This is but an extension of his "road to the Indies."

And how was it to be built, to be paid for? Men by the thousand to dig, to level, to blast rocks, to cut timber, to tear down hills, and fill up valleys, to bridge rivers and chasms, and tunnel mountains—this demanded patience and perseverance that are not common. As we enjoy the fruits are we not liable to be unconscious of the planting—the high purpose, the sagacity, the courage, the energy, the will that secured this comfort to us? Do we remember further that this scheme was thought out and matured in the dark days of the war, days of calamity, of poverty, bankruptcy of national credit, days of gloom, dismay, almost despair? In such a time the project was brought before Congress, and in the face of constant opposition, obstacles whose name was legion, difficulties almost appalling, the measure was carried, the bill passed, the means provided, and the road was built.

But the secret history of this work in its details, the expenditure of vital force—the brain and nerve power—the anxiety, hope deferred, waste of energy upon utterly indifferent and lifeless bodies of men elected to advance the interests of the State, waste of energy in other directions upon the greed and craft, envy and selfishness of other bodies of men, the heart-sinking at times, when it seemed as if all was gone, and the work must stop, this has not yet been written.

This great road makes an open way and rapid transit for California, Nevada, Utah, Colorado, and Kansas into Eastern markets, and Eastern social life. The second day after its opening, one hundred chests of new tea from China made such a passage into New York as had never before been dreamed of. The report of it in China seemed like a story from the Arabian Nights.

Do we older ones remember—what the rising generation does not,—the original style of travel—the prairie schooner, the emigrant train, and journeys of three to six months—then the letter-carrier on snow-shoes, and the pony express? Do we remember the wrecks of wagons that strewed the trail in the sand, the bones of animals, and the graves of mothers and children, and of men that started in strength, the tragedies acted by Donner Lake, and in Death's Valley and Mountain Meadow? That state of things—that style of travel—with all the attaching disasters, might still be our experience to-day had not the thought and energy been exercised and developed that produced such a road.

But what is of more importance to this journal is the question, How does the building of a railroad affect the industrial interests and the mechanic arts? This can be easily illustrated. A journalist once said: "No other enterprise, probably, could be started that would so widely affect the mechanical industries as the building of a great railroad. It has been estimated that it takes the labor of 20,000 men for one working day to build and equip one mile of railway." Suppose 2,000 miles of road is built; on that estimate it will give employment to 140,000 men for 300 working days. Their work is in wood and iron—for the skilled workman. It takes that number of men out of idleness and keeps them active. They and their families must have clothing, and that requires machines and active work. They must have food, and that again requires machines and work also. A road of that length makes a new demand on the foundries and rolling mills, for say 20,000 tons of new rails and for perhaps 300,000 tons of manufactured iron in other forms for locomotives, cars, ties, bridges; these make a demand on the machine shops and nail factories, and these must call on the miners.

Not very many years ago a convention of men in the iron business was called in Pennsylvania to consider the condition of their interests. At that meeting it was stated that nearly one-half the iron mills in the country were idle; that 300 furnaces were out of blast; that 500,000 men were out of work; and this state of things made a difference in the income of labor of $1,000,000 per day; that their prosperity and production depended on the activity of the railroad systems in the country almost wholly, for the railroad took one-half of their entire product.

One of the prominent journals in that State took up the discussion and said: "If we wish to relieve the condition of our iron interests, let the Legislature and Congress awake to a sense of duty and give a new impetus to the debate on the bill for a railroad through the undeveloped territories." The immediate result would be that all these industries would start afresh, for there would be demands for iron in every form, and the steam whistle would scream from every rolling-mill and foundry and machine shop in the State, and locomotive works and steel works, car-wheel and car building shops would be alive with earnest and active men.

About the same time a Galveston journal uttered an unconscious prophecy, when it said: "When such a highway shall be opened across the country, the mineral wealth of Arizona, New Mexico, Texas, and Old Mexico, almost wholly undeveloped, will seek water carriage at Galveston, and where one vessel enters now there will a dozen enter." "Our city will become a depot for all the coffee required in the great States in the West, and send away more cotton than either Mobile or New Orleans." But its prophetic eye did not see the California and Oregon wheat piled up on its wharves.

Such a great road starts all the lumber mills into operation as well as the iron mills. It uses a vast amount of lumber in all shapes, and these mills must do its bidding. Ties for tracks, lumber for stations, for depots, for bridges and trestle work, for tunnels, for workshops, for cars, for snow-sheds, is in demand, and every saw-mill and planing-mill and turning-mill is driven to its utmost capacity so long as the call is kept up.

In addition to the great stimulus that such a work gives directly, for its own uses, to the trade in iron, steel, and lumber, it opens new territory to emigration; individuals, families, colonies take possession of the land and turn it into grain farms and fruit farms, and tools of every description are demanded; the market for every implement used on a farm, in an orchard, in hydraulic mining, in quartz mining, in the great lumber-mills, and flour-mills, and all other industries is immensely enlarged and kept active. New inventions are demanded for new work, as the Little Giant in hydraulic mining, the diamond drill in quartz mining, the cable road, the devices for reducing gold, silver, and copper ores, for gathering great

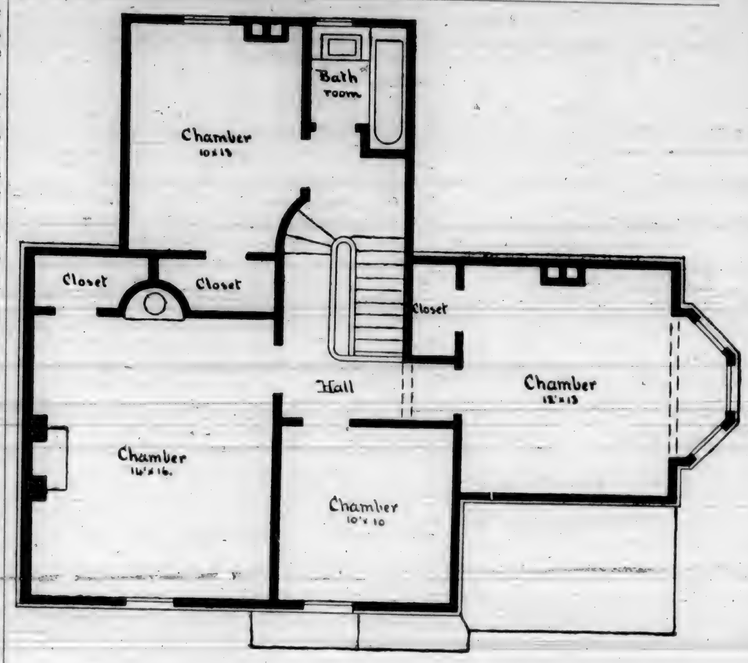

PLATE FOUR.—SECOND FLOOR PLAN OF $4,000 COUNTRY HOME.

crops, for drying fruit, for irrigation, for conducting water to mining districts, and many others, all show how the mechanic arts and industries are stimulated and developed when a new territory is opened for labor, and communication made easy and rapid. Look at these arts and industries as they languished on all this coast under Spanish rule. Then see what they are doing for all the States here now. What will they do for Mexico in the near future?

The Lost Art in Color Making.

BY HENRY E. COLTON.

ONE of the most interesting lectures delivered by the great lecture orator, Wendell Phillips, and which is also reproduced in his published memoirs, was upon the lost arts. At the time of its delivery it was read and commented on by thousands. In that lecture, Mr. Phillips states "that the walls exhumed at Pompeii reveal colors richer than anything we can produce at the present day." Had Mr. Phillips contented himself with saying that they are superior to anything we are now producing for commercial purposes, his statement would have been one of undoubted truth, but it is an absurdity to assert that in the present enlightened state of chemical science throughout the world it is an impossibility to accomplish any result which has been done in the past time. The colors of the ancients were limited to a small number, while the shades with which we ornament our villas, and fresco our houses and public buildings are numbered by hundreds. The use of colors is an evidence of civilization, and the character of those colors an indication of the nature of the people who use them. The warm, sensuous Egyptians and Greeks ornamented their houses and their bodies with the glowing scarlets and purples, and the softer blue was with them the color of love and divinity. In comparison with the varied and brilliant shades produced by our own manufacturers, the colors of the ancients were inferior, but, when compared in point of durability, those of the Egyptians and Greeks have decidedly the advantage. Had Mr. Phillips stated this fact there could not have been a possibility of successful contradiction; at the same time it must be understood that those colors are not more durable than any our manufactures and chemists can make, but more durable in tint than any they *do* make.

The colors used by the ancients were not chemical; they were natural vegetable and mineral substances, or were made by fire processes. Their black was, for many years, made from the charcoal of vine twigs and wine lees. Appelle, a Greek, invented the process of making black from ivory clippings, and to this day no improvement has been made upon his invention. Their red was, for a long time, a very brilliant ochre from Palestine, and afterwards, the native cinnabar from Spain. Their blue was a carbonate of copper ground very fine. Their yellow was from two sources, the expressed juice of some plant, and an ochre. Their white was a preparation of lime. The painting of the ancient Egyptians does not deserve that name; it was simply skillful plastering. The color was mixed in the lime or cement of which the wall was to be made, or it was put on while the cement was still wet, so as to strike in. The tools used were a rough brush made of bamboo fiber, a pointed instrument and a spatula. With the pointed instrument the artist marked out the lines of the figures, and with the brush or spatula, his assistant put on the color. There are numerous pictures in the British Museum which exhibit these persons at work, and like everything else of that Egyptian day, they plainly indicate the heavy mechanical nature of the work. All their figures were stiff, without elegance in shape or grouping, and they knew nothing of mixing colors so as to produce varied shades. The Greeks derived their colors from the Egyptians, and improved on them. The age of Appelles marks an era in the history of ancient paints and painting. He not only discovered a richer black, but also introduced the mixing of colors for producing shades, and he also introduced an improvement in the mural or plastic system of painting whereby the tints were made brighter and more fresh-looking. And we may add that this very system of frescoing is constantly used at the present day, being considered by some a great secret. The basis of it consists in mixing the color with glue, water, and wax. Appelles also discovered and used a mixture of oil and gum in his painting, but did not give it fully to the public. Previous to his day painting had been merely a species of mural decoration incorporated into the wall and immovable, but with his improvements he introduced also a system of painting on wooden boards, which might be affixed to the walls, or used as paneling. He seems, too, not to have lacked appreciation, for upon discovering his purple, he first used it on a portrait in which he clothed the great Alexander in the royal color, who was so much pleased thereat that he paid the artist a sum equal in our money to $50,000 gold.

It is thus seen what were the colors of the ancients. The chief colors of the present day are, with one exception, all made by chemical processes in the wet way; ultramarine is the only one which the civilized nations make with a fire process. It is generally thought and believed that the Chinese make quicksilver vermillion by a fire process, and hence its much greater durability and richness of tint. In this simple difference of manufacture lies the secret of the opposite qualities of the ancient and modern colors. The latter are brilliant, but a few months of sun and rain and the luster is gone; the former may not be originally so brilliant, but hundreds of years do not dim its surface or change its tint. The president of the American Color Manufacturer's Association not long since said it would not pay to make colors by a fire process.

This simple statement is the key to the whole mystery of deterioration in modern color-making. The manufacturers, in the thirst to get rich or to make sales, have striven for the production of an article which could be made at cheap rates and show well while being sold, and have not cared or striven to achieve durability in material or tint. The public taste, instead of being elevated by the offer of something better, has been constantly debased by the inducement of cheapness. If, instead of striving to see how much base material a little true color would tint, the color manufacturers had been for these years past striving to produce durable colors at cheap rates, their profits would not have been materially decreased, as they would have kept from the business those who do not value reputation, but only work for present profit, and they would have sustained for their business the reputation it deserves from the high character of some of the men engaged in it. The public taste is slowly and surely demanding something more permanent than the gaudy to-day and pale to-morrow tints now sent forth from the shops. There is no lost art. Our chemists can make more perfect colors, and our painter artists can use them more skillfully than any of the ancient Egyptians, Greeks, or Romans.—*Nashville Artisan.*

Wooden and Brick Buildings, 2 vols. Price $18.00.

Cleanliness of Sinks.

ONE of the most prolific causes of defilement and offensive odors in kitchen sinks and their outlets is the presence of decaying grease. This comes from the emptyings of kettles in which meat has been cooked, in the dish water, and in the soap. The grease lodges in every crevice, and catches at every obstruction. A remedy may be found in the use of the common alkalies instead of soap, aqua ammonia in washing clothes, and borax in washing lawns and laces, and washing soda in cleaning dishes. These alkalies prevent a solid soap from forming in the sink and its pipes, and neutralize all effects of decomposing fat.

A NEW WORK.

Steel Square and Geometrical Problems

THIS is a revised and greatly enlarged edition of a work by the author of "Carpenter's and Builder's Assistant," "American Stair Builder's Guide," etc. It contains 108 pages, fully illustrated. Explicit directions are given for solving many of the problems that so frequently vex the mechanic, and the explanations are made in language so plain that the apprentice can as readily understand them as the master mechanic.

Price ..... $1.00, post-paid.

We have been appointed sole agents on the the Pacific Coast for the above work.

Modern House Painting. Price $5.00.
Street, Store and Bank Fronts. Price $4.00
Plasterer's Manual, enlarged. Price 75c.

Drawer Making.

MOST articles of furniture being fitted with drawers, the method of making, fitting, etc., forms a very important branch of cabinet making. I shall, before describing the manner adopted, make a few remarks respecting the work into which they are fitted, and other essential particulars. Drawers are most frequently placed one above the other in carcasses, being supported and separated in front by partitions. These partitions play a very important part in the structure, and one to which sufficient attention is not usually given. I shall, for the sake of illustration, assume that we are making a cabinet about twenty inches or so wide. I need not enter into details, but will suppose that it is to be constructed with two or three drawers, placed over each other in front. The ends, having been planed over, both inside and out, should be squared up. For this purpose they must be fixed together. This is done by means of a small handscrew at the edges, or by nailing them in four places near each corner. All work intended to receive drawers should be squared up a little out of the square. It should be a trifle wider at the back than the front, and also a little higher. A very small amount will do; it must not, of course, show to any perceptible extent; about one-eighth inch is quite sufficient.

The tops and bottoms for your carcass should be of three-fourths inch pine; in larger work you may with advantage increase this thickness. You should get them out 1¼ inches longer than the inside measure your work is to be. This will allow three-fourths inch nearly each side for dovetailing into the ends. This thickness of wood will work about five-eighths inch, and you should have your partitions finish the same, to keep all the front in unison. The position of the drawers is now set out on the inside front edge of one end, and the other marked from this. You must first mark the top and bottom thickness, and then divide remaining space for your drawers, carefully marking the top and bottom of each partition edge. From these markings the ends are squared across, and grooved to a depth of one-fourth inch with an iron to correspond with the thickness of the edges. The partition edges should be of sound, seasoned pine, three-fourths inch thick, and 2½ inches wide.

In larger work it is advisable to use a little thicker and wider stuff. They must be got out two inches longer than your drawer fronts are to finish. Their front edges are slipped or faced with similar wood to what you are making the cabinet of, the slips and edges being toothed before gluing together. The back edges are plowed about one-half inch deep, with a three-sixteenths inch iron. The tops and bottoms having been dovetailed together, these partition edges should be tightly dovetailed in from the front edges and cramped up. The dovetails should be three-quarters the thickness of the ends long. In some cases, where the drawers stand back in work, it is impossible to put in the edges in this manner. They should then be tenoned in and cramped. You will require some runners; they should be of pine. Get them out the length the drawers are to be, and an inch, or rather more, wide. They are plowed on one edge with the same iron as used for the partition edges, and about the same depth. Take them to the requisite thickness—that of the carcass end grooves. Be very particular with this; they must fit well. The best way is to get a piece of wood and groove it similar to your ends.

Now, after taking the runners to a thickness, just try whether they will all draw tightly through it. You will be able to see where a shaving or two is wanted off. You must tenon them into the back edge of the partition rail. Now glue the mortise, knock them into the rail and into the carcass grooves. It is unnecessary to glue them; but it is better to put a screw through the runners at the back into the ends. The next thing is to get out some partitions. They should be of very dry, seasoned wood; pine will do very well. Their thickness should be about that of nine-cut stuff; the length a little more than that between the runners, allowing for the plow grooves each side and a little additional, say one-eighth inch, for working. For most purposes the width of a board, eleven inches, is sufficient; but if the carcass is very wide, it should be greater. These partitions are smoothed over, and the front and one edge squared, then chamfered, until they will fit the grooves in partition edges and runners pretty tightly. Now put the camfered side in the runner. Remember, the direction of the grain of the partition should be across, the same as in the partition edge in front; mark its length, square this across, and chamfer it the same as before. Then remove any glue that may be in the grooves of the partition edges and runners, where the tenons are, with a narrow chisel, run your partition in, and drive them home into the edges with one or two blows with a mallet.

Sometimes drawers are placed side by side, as in the top frame of a library table, which usually contains three, or the front of a dressing table with two. In both cases the method of construction is very similar. The top and bottom rails forming the partition edges will be in the library table, or anything similar, dovetailed into the ends from the top and bottom respectively. In the dressing table, which would be supported on legs, the top rail only would be dovetailed in, the bottom one being tenoned into the legs. The width of all these rails may be from three inches to four inches, and their thickness, assuming the jobs are made about four feet wide, should be seven-eighths inch finished. The other partitions separating the two or three drawers, the dividing partitions, will be tenoned into the top and bottom rails. They should be got out long enough for the tenons to come right through, the projecting ends being afterward cut off. Underneath and above each dividing partition a cross rail or rails should be tenoned into the front rails and dovetailed into the top and bottom of the back frame.

It is necessary to get out some pieces to act as guides, and glue them on the bottom cross rails up to the dividing partitions in front. They need not be very wide, three-fourths inch or one inch will do; their length that of the drawer sides, and their thickness the same as the dividing partitions. You should work them underneath, then glue, and set them square with the dividing partitions. This is best done by running a square along the front rails, and putting the girders up to its edge. In a dressing or toilet table there will be a space at each side, because the end framing will be mortised and tenoned into the legs. This space, the difference between the framing and the square at the top of the legs, must be filled up level. This will be all that is requisite; it is not necessary to use runners with partitions fitting into them, as in carcass work, because the difficulty we have to counteract there, that of the tendency of the ends to cast, does not here exist. Partitions may be used in a dressing table; they are useful for preventing the drawers getting so dirty; but they merely act as dust boards, and are not essential to the structure.

Drawers have occasionally to be fitted into work where they are placed at the back of it, and draw forward over another portion of it, like those in small cabinets, writing tables, and secretaries. They are in these cases usually much smaller than in those previously described. When in this position they should never be allowed to be level with that portion of the work they draw over. They must work on a bottom. This should be one-eighth inch, or rather more, thick and one-fourth inch wider than the drawers from back to front. It is fitted in and the ends mitered; now fit same thickness in at each end, and in the middle or wherever the drawer divisions are to be. All these should be about two inches wide, and put in in the same manner. To these partition girders are fitted as before described.

The foregoing examples include most cases in which drawers are met with, although they are sometimes, either for want of space, or because the work is of a miniature description, fitted in carcasses without partition edges. They often work on tongues. There is nothing special in the construction in this case. The ends should be set out and plowed for the tongues about three-eighths inch deep. These grooves should be well glass-papered before putting together.

In selecting wood for drawer making, care should be taken to select that which from its nature is most suitable. What is required is a straight, firm, durable wood, one whose surface will offer or present the least friction when in use. This is especially necessary for the sides. The best woods are oak, teak, and mahogany for large and medium-sized work; for smaller work sycamore and boxwood may be used. You will readily observe the different appearance and nature of either of these compared with a softer wood like pine, or one of a sticky or gummy nature like cedar.—*Building News.*

Enlarging the Dining Rooms.

In the good old times when the mistress and her daughters did all the housework there was not the necessity for a room consecrated to ornamental china and fancy cooking that is now felt in all well regulated and high toned families. Indeed, the clean, bright, open kitchen with its sanded or polished floor was a very comfortable and convenient place for the family to assemble, not only for their evening work and amusement, but for their daily bread. When the mistress retired from the kitchen and gave up its care and management to subordinates the change in that department is scarcely less than the modification of the style of living throughout the house. From being an inviting place it became an uncomfortable and confused workshop whose appearance and character were highly uncertain. Generally the modern dining-room is an apartment devoted to a special purpose. In families where the old fashion of doing her own work is kept up by the mistress it is practical to use this room even for a sitting-room, but if the business of clearing and setting the table is carried on by the ordinary kitchen servant it must be abandoned by the rest of the family so large a part of the time that it cannot well be made to serve anything else than its one legitimate purpose. In many houses, especially those that were built several years ago, there was a sort of compromise by making this room very small, barely large enough to contain the table and its row of chairs, consequently houses otherwise capacious are often found with a dining-room of altogether inadequate dimensions. In houses that are blessed with hospitable intentions this should be at least as large as any other single apartment in the house. How to get more room is a question more commonly asked in regard to the dining-room than of any other in the house, unless the front hall be excepted. Like the familiar advice concerning the resumption of specie payments it may be said that the best way to enlarge a dining-room is to enlarge it. If this cannot be done without encroaching upon other rooms of the house which are already small enough, then space must be taken from outside. As tables are arranged in a majority of cases the first demand is for more length. Many rooms which would be large enough if it were not for a projecting chimney breast or sideboard, are cramped by these articles so as to be practically of very small size. Hence if a recess can be made to contain the sideboard with space enough around it for the servant who waits upon the table to stand without encroaching upon the room itself, such an addition will add to the capacity of the room just as much as if the whole side were extended, and the saving of cost as well as the improved appearance will be very great. Of course this suggestion is only intended for houses and buildings which feel their limitation in this respect, and there is great satisfaction in treating a defect in such a way as to convert it into an actual advantage.—*The Builder*.

Paper Hanging.

The art of putting on, or "hanging" paper is very simple and is easily learned; but to make tasteful choice of paper for various situations is not so easy, hence the following remarks, which may be of service to the workman or others on whom the selection of paper may devolve.

Walls to a room should be regarded only in the light of a framework to what the room contains, and should be decorated so as to bring into prominence, and not eclipse, the other parts of the chamber. Nothing destroys the effect of a room so much as a handsome but staring wall paper, or a wall so profusely ornamented as to strike upon the eye to the exclusion of the rest of the decorations, thus bringing forward what should be the background into the most conspicuous place. A modern drawing-room is always difficult to decorate artistically, because of the taste of its builders for heavy cornices, prominent mantelpieces, and rooms too lofty for their size; and as all these misnamed "embellishments" are too costly to remove by tenants, the only plan to pursue is to destroy their effect by exercising both taste and ingenuity. First, with regard to the ceiling, the ornamental plaster boss in its center should be removed and the ceiling tinted a color that harmonizes with the wall paper, as no harmonies can be hoped for when what produces them is surmounted with the glaring white of an ordinary ceiling. The tint used must be one that softens into the wall paper, not one that contrasts; thus, if the tone of the room is that of a soft gray-blue, the ceiling should be a clear flesh-pink; or should a gray-green picked out with black be the chosen color, then it should be colored a subdued lemon.

Some people cover their ceilings with a whole colored paper and border it with a stenciled pattern representing the thin garlands so familiar upon Queen Anne decorations; but this is a more troublesome plan than the simple coloring, which answers all the purpose. The walls, if they are lofty, require a high dado. These high dadoes give a look of comfort and "home" that is absent from the modern, high-pitched room papered with one uniform pattern. The dado is divided three feet to four feet from the ceiling, and the coloring of the lower portion must always be heavier than that used on the upper, or a top-heavy look will be given to the room. When many pictures are to be hung up, the lower part of the dado should be of a whole color, either a whole colored paper, or a painted wall, as pictures are only shown off upon such a background. Where a whole tint is used for the lower part of the dado, the upper portion should be decorated with a frieze paper of a good, bold pattern, but of subdued coloring and of tint that harmonizes with the lower. Thus, the color used about the frieze should be the same as that on the lower part, but of a lighter shade, intermixed with some other colors that form a harmonious link between the two shades. Contrasts must be carefully avoided, but pale pinks, blues, and ambers can be blended together above a subdued gray-blue ground. The two portions of the dado should be joined together with a light wooden (black or brown) railing, or with a line of paint.

The dado decoration can be altered by placing the pattern paper upon the lower part and leaving the upper part plain colored, with or without a stenciled pattern upon it. This will suit a room where not many pictures are required, or that is already rather dark. Some part of the wall should always be in plain color, as the eye requires rest; and no pattern, however subdued in hue, can give the relief to the mind that a bit of plain coloring affords; and this scarcity of ornament in one part of the room is amply repaid by the effect it gives to such parts as are bright and should be bright. The true theory of effect is to use but one or two bright colors in a room, and to surround them by soft and subdued tints that throw up and do not destroy their brilliancy; a number of bright colors placed together destroy each other, and leave no impression upon the mind but glare and vulgarity. Having settled upon your paper and ceiling, have the woodwork and cornice of the room painted either a shade lighter or darker than the walls, and shroud up the mantelpiece with curtains, etc., of satin sheeting embroidered with crewels, and instead of the usual looking-glass over the fireplace, have a mirror surrounded with brackets holding china, or have a black, wooden mantelpiece made with squares of looking glass set in. The background of your room being thus completed in a manner really to be a background, your furniture will look twice as well as if it were stared out of countenance by the walls; and one need hardly add that all your friends will delight in a room that throws up and brings out their dresses and faces, instead of killing them by its glaring tints.—*The Paper World*.

Gaswork Washings for the Sewers.

It has been discovered that the best disinfectant for sewer gases is the washings from gas works. This serves a double purpose—that of annulling the poisonous effect of the sewer gas and at the same time enabling persons having defective traps to detect it by the strong, pungent odor arising therefrom, while sewer gas alone, almost ordorless, permeates the building, carrying sickness and death with it. The washings from gas works, at least, will not clog or obstruct even the smallest of sewers, while their presence, as above stated, might save valuable life.

Grimshaw on Saws. Price $4.00.
Mechanics' Geometry. Price $5.00.

The Egyptian Sphynx.

On the western bank of the Nile, and near the second largest pyramid, stands this famous object, which has from time immemorial so excited the awe and curiosity of the traveler. As long ago as the time of Herodotus, the first man who ever conceived the idea of writing a history, and who lived four or five hundred years before the time of Christ, this gigantic and mysterious human head was raised above the sand, looking upon the beholder with the same calm and serene expression, as if superior to the vexations of life, and to the mutations of time, as much a puzzle as it is in our own day. It was then hoary with age, though over two thousand years have since rolled away. First the Persians, under Cambyses, before Herodotus' time, invaded and devastated the country. Then the Greeks, under Alexander and the Ptolemys, his successors; then the Moslems, one of whom, as a hater of images, sought in vain to destroy it; and then many other lesser powers down to the Turks of the present day; all alike unaffected by any respect for the monuments of antiquity, and ignorant of their value as records of human progress and decay.

The deep mist and darkness of the middle Ages rolled over it for centuries, and still the Sphynx remains one of the wonders of the ancient world, mutilated, disfigured, neglected, and sometimes almost forgotten, but always serene, impressive, and awe-inspiring.

It is hewn from the salient angle of the rocky ledge on which stand the great pyramids; part of the cap, the back, and the fore-paws, when the rock was abraded, being supplied by masonry. The savants, under Napoleon, uncovered the back and shoulders, and obtained approximate measurements; but it was not until 1818 that the entire figure was displayed to its pedestal. The honor of this work is due to the Italian Caviglia. The loose sand, anciently restrained by artificial irrigation, and doubtless highly cultivated, but now continually shifting about in that rainless country with the slightest breath of air, was removed by the labor of from sixty to eighty persons for several days. No trace of these excavations, made at so much cost, now remains; the upper part of the figure alone being seen, rising as before about thirty or forty feet above the level of the soil. It faces eastward toward the Nile. At the rear is the pyramid of Shafra, while toward the north, in a corresponding position in reference to the pyramid, stands another rock, which, in the opinion of Lepsius, it may have been the intention of the builder to carve into another Sphynx, as a twin guardian of the approach to the sacred pile.

Caviglia's efforts laid bare a descent from the Nile for 135 feet succeeded by a flight of thirteen steps, after which was a platform and a second flight of thirty steps to the rocky pavement on which the figure rests. The body is that of a lion, with human head and shoulders. Though often spoken of as feminine in features, the broken fragments of a beard which have been found demonstrate the incorrectness of the assertion. Indeed among thousands of sphynxes found in Egypt, but one is known having a female head, though those of the Greeks are almost always male.

The posture is recumbent, with the forepaws stretched out in front a distance of fifty feet. The body is 143 feet long, and the height to the top of the head is 62 feet. Between the forepaws is a level space which was used as a temple or a place of sacrifice. Here were the remains of an altar with charred embers still preserved—the relics of a sacrifice offered, perhaps, to avert the tide of invasion that overwhelmed the worshipers. Several small sphynx-like figures stood near or under the chin. Under the chin is an immense granite tablet, fourteen feet high, seven broad, and two thick, covered with hieroglyphics relating to one Thothmes IV., and flanked by two other tablets of limestone. These formed part of the inclosure of the sacred area.

The traveler, Dr. Pococke, asserts that there are openings in the back and in the top of the head; but these could have been nothing but seams in the rock, or spaces left by dislodgment of parts of the masonry, as Lepsius, a most careful observer, who visited it in 1843, states that no opening to the interior whatever was to be seen, and that the mass of the statue obviously must have been hewn from the native rock.

The following striking passage as to its present appearance is from Denon:—

"Though its proportions are colossal, its outline is pure and graceful, and the expression mild, gracious, and tranquil. The character is African, but the mouth, the lips of which are thick, has a softness and delicacy of execution truly admirable. That it is an Egyptian head is plainly evident, notwithstanding the mutilation; but the type is fuller and broader than usual in Egyptian statues."—*Illustrated World*.

Spearing for Timber.

A new industry has recently been developed in Ireland—a sort of timber prospecting never dreamed of by our American pine hunters. It is a well-known geological fact, says the *Northwestern Lumberman*, that immense tracts that are now bog lands in Ireland were once covered with forests of oak and pine, and that in cutting peat, immense trees of these varieties are found imbedded in the earth at depths of ten, twenty and thirty feet, in many cases whole groves being found standing just as they grew. To find out the location of these miniature subterranean forests is now the speculative work in which some industrious Irishmen are engaged. The timber, when brought to the surface, is found to be perfectly sound, and the oak, which is as black as ebony, is used extensively for ornaments of jewelry and fancy cabinet work, and sells at high prices. A recent visitor to the wild moor and mountain region of Donegal thus describes the way in which the seekers after buried forests operate: Two men, armed with steel rods about thirty feet long, traverse the bog, and by running their rods into the ground are able to ascertain where the trees are to be found. They work by what may be termed natural mathematics, and quickly determine the length of their prize, its approximate diameter, whether it is pine or oak, and is or is not a clumper—one of a company or clump. They fix on twenty or thirty feet square, and cross it with their searchers, say north and south, and then east and west, search it across each way, a stab to each foot or so, and in the course of a few minutes they know whether that area contains what they are looking for. The square lying next and next, and all near each other, are so searched, and the discoveries, if any, are marked for future action. The unproductive are also marked, to avoid future loss of labor.

RIDDELL'S WORKS.

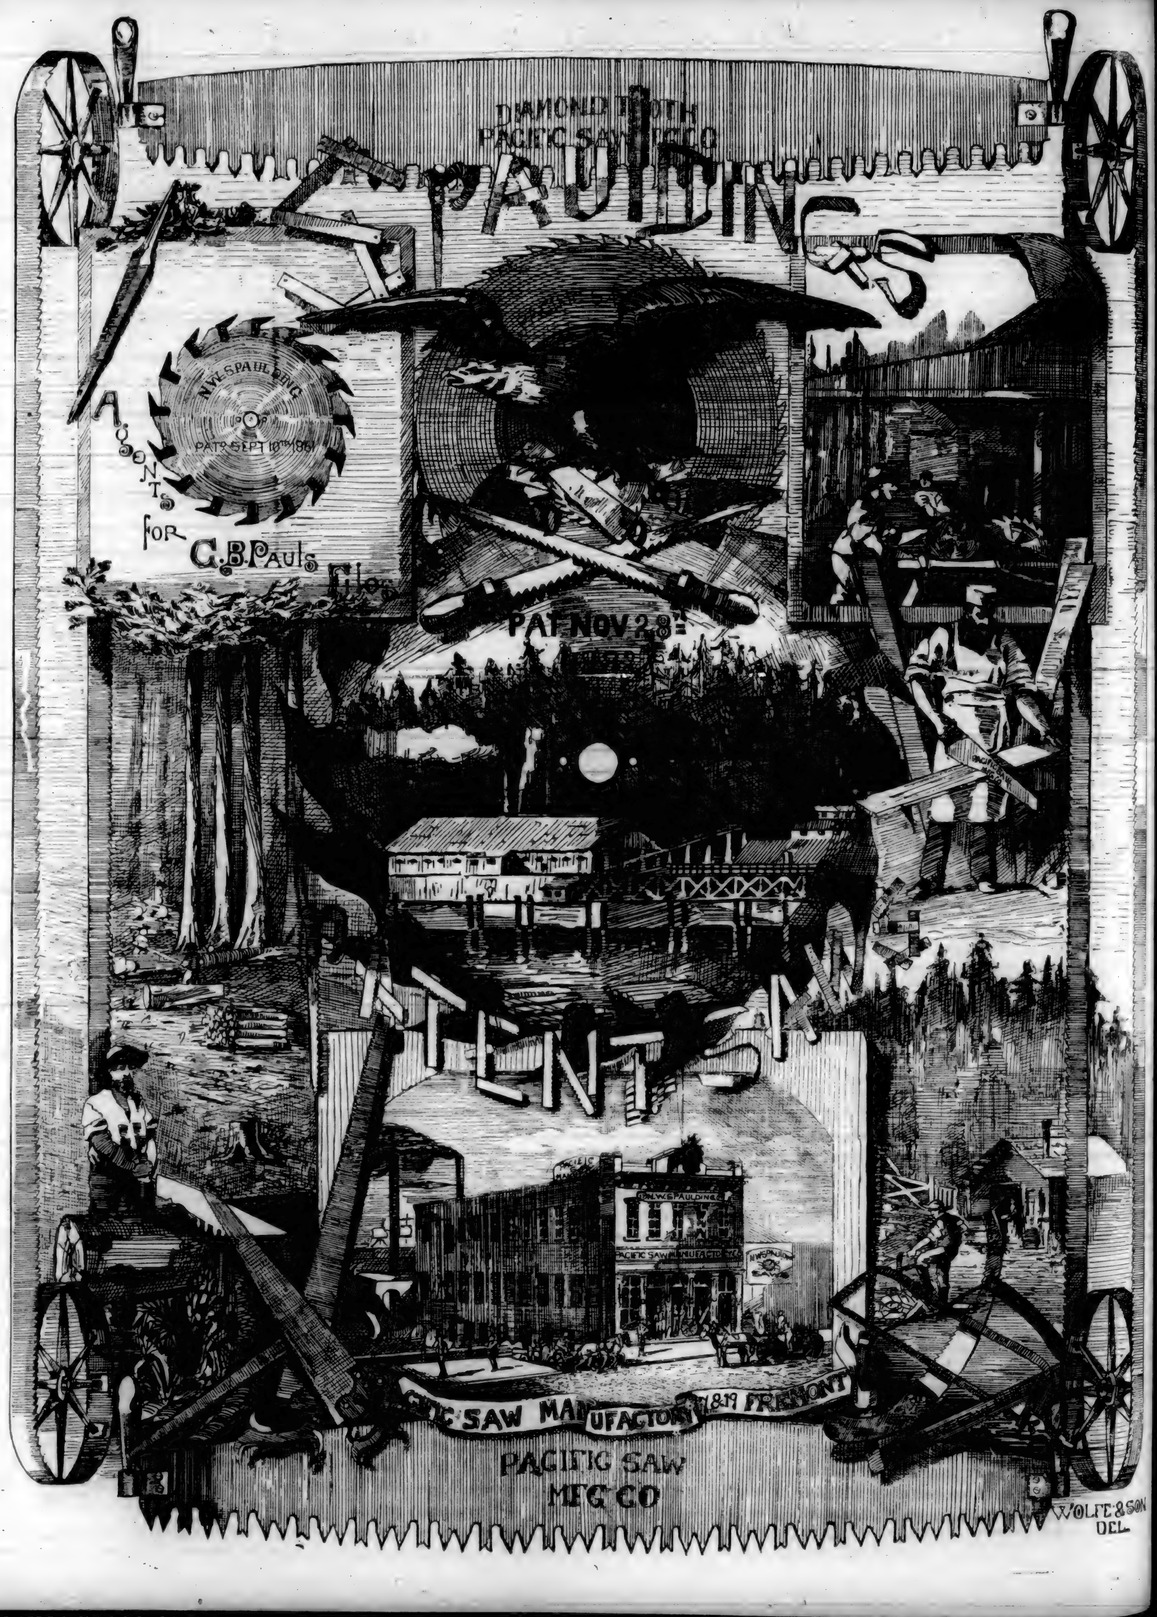
MECHANICS' GEOMETRY, OR SCIENCE OF FRAMING WITH THE AID OF CARD-BOARD MODELS—Should be in the possession of every mechanic on the Coast. Sent post-paid upon the receipt of $5.00.
THE ARTISAN—The mechanic's own book should be studied every spare moment. Price, $5.00.
CARPENTER AND JOINER MODERNIZED—Third edition, revised and corrected, containing new matter of interest to the carpenter, stair-builder, cabinetmaker, joiner, and mason. Price, $7.50.
NEW ELEMENTS OF HAND-RAILING—Contains forty-one pages, thirteen of which are now for the first time presented. Price, $7.00.
LESSONS ON HAND-RAILING FOR LEARNERS—Third edition. Price, $5.00.
Any of the above will be sent by mail, post-paid, upon receipt of price.

The Triennial Conclave Gathering.

It has come and gone since our last issue, and left no other than the most pleasing reflection. We can add not a word more to the many good things that have been said of us and to us as a people. Our Eastern friends came among us in uncertainty, not knowing whether we were a peculiar people, or a large-hearted, generous branch of the human family. It is safe to say that all questions upon these points have been fully settled—largely in favor of the latter proposition. The Knights of California and the Masonic fraternity generally have special reason to feel proud of the grand affair in its entirety, and the citizens of S. F. as a whole cannot but mingle in sentiment with their specially interested brethren. The occasion will never be forgotten by those who participated in or witnessed the many interesting displays, and in the future, the influence of what has been is sure to prove of very great benefit to our State. We return hearty greetings to the many noble Knights who called personally at the office of this journal.

Cottage Homes.

Comstock has sent us a neatly printed work with the above title. Being perfectly new, many new designs are found in it, representing the latest phase of New York architectural styles. Price, $5.00.



Pacific Saw Manufacturing Company.

NEARLY twenty years ago, N. W. Spaulding, James Patterson, and C. P. Sheffield conceived the idea of establishing upon this coast a MANUFACTORY for the purpose of making every kind of saws known to the trade. Beginning in a small way, at a place on Pine Street between Front and Battery, they succeeded at once in attracting attention by the excellent manner in which they turned out their work. The introduction about this time of Spaulding's improvement of inserted teeth attracted the attention of saw-men generally all over the United States, and the young firm was soon crowded with orders. Larger premises became a necessity, and the present quarters on Fremont Street were secured. Within the past few months a further extension has been added, in order to keep pace with the demand that has been increasing from year to year. East of the Rocky Mountains orders have been received for the saws of this company, and they are gradually, but surely, working their way into general use in all the main lumbering districts of the United States. A specialty of this company is the manufacture of the N. W. Spaulding Patent Circular Saw and Plate, with inserted adjustable teeth. This is an invention of incalculable value to the lumbermen and sawyers, as the plate of the ordinary saw, which is very expensive, becomes useless when the teeth are worn out. But this patent plate is so constructed that when the teeth are worn out they can be detached and new ones inserted, thus affording the advantages of a *new saw* at a nominal expense.

The cross-cut saws manufactured by this company are achieving a national reputation. They excel in the perfect manner in which they are ground, forming a true taper from the point of the tooth to the back of the saw. The excellent material used, and the improved method of tempering, enables these saws to carry their cutting-edge for a much longer time than most of the imported saws.

Saws of all sizes and descriptions are made by this company; circular-saws, seventy-two inches in diameter, milling-saws sixteen feet in length, the finest dentist and butcher-saws, pruning and hand-saws; in fact, every kind known to the trade.

Carpenters have discovered that the saws manufactured by this company are superior in temper to many others; and although the first cost is greater, this is made up in a short time by the saving of files and time necessary for putting them in order. Workmen have found out that saws easy to file are but trash. More attention is being paid by all of our saw manufacturers to having hand-saws of a harder temper than formerly given.

Our engraving represents many of the different kinds of saws made by this company. About fifty men are now employed under the immediate superintendence of the proprietors. No cheap work is allowed to leave the establishment, every saw being inspected by a member of the firm before it is placed in the market. Should at any time a saw with the name of this company stamped upon it be found to contain defects, it will be remedied without additional charge, or a new one be substituted.

This company has the most complete and ample facilities for the manufacture of saw mandrels, planing and curriers' knives, springs, etc., also for repairing in all its branches, re-tempering, strengthening, gumming, grinding, polishing, etc.

American House Carpenter. Price $5.00.

Hemacite Door Knobs.

ARTISTIC in design and finish, of material as durable as iron, with the assurance that once placed properly in position no ordinary wear and tear can in the least harm them, these KNOBS stand to-day almost without a rival. The beautiful designs and ornamentation of these knobs at once attract attention, and their low price is the death knell to the old-fashioned white knobs. They can be obtained from $6.00 to $24.00 per dozen pairs, depending altogether upon the amount of work on the kind you select. The PRINCIPLE of their construction is the same whether you get the lowest or the highest price quality. They are guaranteed to outlast any other knob now before the public. They can be obtained at almost any hardware store. Some of the highest priced are not kept in stock, but any one wishing to obtain them can select the pattern from any of those in the illustrated catalogue, issued by the company and it will take but a short time to get them direct from the factory. Information in regard to these knobs can be obtained from hardware dealers, the office of this Journal, or direct from the Dibblee Manufacturing Company, Trenton, New Jersey.

The Protection of Iron Against Rust.

IT is still an open question how best to protect iron against oxydation, commonly known as rust. He who would find an effective preservative would indeed be a benefactor, for by its means numerous noble structures, into which the tooth of time is now eating slowly but surely, would be preserved to posterity. It is well known that wherever air and damp come in contact with even the smoothest iron surface, rust soon makes its appearance. By its operation not only is there a constant waste going on, but the remaining iron is rendered brittle. A coating of less oxidizable metals, such as tin, later lead, and zinc, and quite recently nickel, has, therefore, been applied, and with some effect. Earthy glazes, such as are applied to pottery, have also been used for coating iron vessels for household purposes. But all these coatings of metals or glazes have been found in most cases either impracticable in application or too expensive. For extensive use, coatings consisting of oils mixed with metallic oxides, earths, etc., have thus come into use.

Now, it has been observed that iron does not rust in dry air, even in dry oxygen. Iron, also, frequently does not suffer when exposed, without being painted, to the open air—weather-cocks, fences, etc., having lasted for centuries. But in that case it has been found that they have been protected by the formation of a thin layer of peroxide of iron, which has acted as a safe covering against exterior influences. This experience led to the artificial production of a layer of magnetic oxide, superheated steam being used for the purpose. It is not to be supposed that such a treatment will find extended application; and a protective covering obtained in this way would only be effective in the case of iron in pure air, but not where it comes in repeated contact with water or carbonic acid. An interesting phenomenon has likewise been observed on railways. It has been found that iron sleepers and spikes rust very much if the line is not used for some time. It is assumed that iron bodies are more liable to rust in a state of rest than if they are exposed to vibration from time to time, in which case perhaps an electrical effect comes into play, which lessens the affinity of iron to oxygen.

In demolishing old buildings, there are often found iron cramps, blocks, etc., which, so far as they are surrounded by mortar, are completely free from rust, just as if they had only left the forge. A similar phenomenon has been met with by M. Vicat, a French engineer, when he had the anchor fastenings of several suspension bridges exposed which had been put down thirty years before. Where the iron in the masonry was surrounded by rich lime mortar, there was not a sign of the formation of rust, whilst the continuations of the anchors in hollow spaces were rusted to such a degree as to have lost two-thirds of their former dimensions. It has been frequently observed that iron does not oxidize in water if small quantities of caustic alkalies, or alkaline earths, are solved in it, in which case acids of whatever nature would be excluded. It appears that the above experiences have served as the basis for the rust-protective paints, invented by Herr A. Riegelmann, of Hanau (Bavaria). He adds to his paints caustic alkaline earths (barytes, strontian, etc.). By coating iron with them, it is said to be in the same state as the anchors of suspension bridges in lime mortar. Although simple coatings of such paints, owing to their slight thickness, cannot contain much alkaline matter, as is the case in walling in iron, alkaline effects will show themselves as long as they contain a certain percentage of it. But in any case those paints are free from active acids, which cannot be said of all our paints for iron. Should the paint be found in practice to possess the protective properties claimed for it, a step in advance would have been taken in the preservation of iron, and its greater application would be ensured.—*The Builder.*

Modern House Painting. Price $5.00.
Street, Store and Bank Fronts. Price $4.00
Plasterer's Manual, enlarged. Price 75c.

BUILDING INTELLIGENCE.

SAN FRANCISCO.

Sutter, near Stockton. Repairs to Druid's Hall.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 252 Market St., S. F.

FOR WEEK ENDING AUGUST 28, 1883.

283,855.—Watch Holder—W. W. Blow, Oakland, Cal.
282,870.—Blackboard Rubber—John Dooner, S. F.
283,908.—Roof Scaffolding—A. B. Manley, San Jose.
283,909.—Flour Bin and Sifter—A. B. Manley, San Jose.
284,038.—Sawing Machine.—George McCoy, New Dungeness, W. T.
284,051.—Egg Boiler—W. P. & W. B. O'Brien, Jr., Santa Clara, Cal.
284,134.—Steam Boiler for Traction Engines—L. F. Lillard, Dixon, Cal.
284,067.—Diamond Drill Safety Machine—Ross & Grant, Virginia, Nev.
283,930.—Return Crate—Smith & Morton, S. F.
283,826.—Last—W. H. Snyder, S. F.
283,937.—Dump Wagon—George M. Wallace, Yuba City, Cal.
283,941.—Window Blind—Joseph Williams, San Jose.
284 157.—Metallic Railway Tie—J. W. Young, Fort Moroni, A. T.

Note.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, per square, each insertion	$ 2 50
Back " " " " " "	2 00
Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.
NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.
A square is ¼ of an inch in length by width of the column.
When money is sent for subscriptions, the receipt of a copy of this Journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

SPECIAL NOTICE TO SUBSCRIBERS.

It is our intention, in the future, to have all new subscriptions begin either with the January or July numbers. In order to have a uniform time with subscribers now on our books, credit will be given to those whose subscriptions fall due between this issue and the 1st of January, with the intervening months, so that by sending $2.00 NOW, you will receive a full receipt for 1884. All new subscribers will receive the balance of this year free.

VOLUME IV.
NUMBER 10.

SAN FRANCISCO, OCTOBER, 1883.

$2.00 per Annum, in Advance.
Single Copies, 20 Cents.

Future Prospects.

EVERY one interested in real estate and improved property very naturally desires to be correctly informed as to the building probabilities of the future. At the commencement of 1883, a large number of property owners expressed doubt as to the advisability of increasing the number of dwelling houses in S. F.,—contending as many did that the supply was then fully equal to the immediate and prospective demands; and that any considerable increase in the erection of buildings would necessarily create a surplus of rentable houses, and cause a decline in rents. While this may have proved true to some extent, as far as some of the inside property is concerned—which may not now be in as great demand as heretofore—at old rates, it has not proved true in the outside districts, where a very lively building enthusiasm has prevailed, and hundreds of new houses been erected during the past nine months, seemingly without increasing the surplus. And while there is at present a lull in building operations, as shown by our present monthly report, the general feeling is excellent, with well assured probabilities that fair activities will rule during the winter months. And from the many facts in our possession, we are warranted in predicting a very lively condition of things during the early spring months, not only in dwelling and tenement houses, but in substantial brick structures. The only thing likely to interfere with future activities will be increase in price of material beyond fair and reasonable rates of profit; and we regret that there is too much of a disposition among producers of building materials to crowd up prices, all that circumstances and the patience of consumers will bear. Reasonable, fair, and legitimate profits seem not to satisfy, so long as there is an opportunity to increase and pile on the weights without breaking the cords.

Good Times Continue.

OWING to the large number of buildings reported by us during the earlier months of the present year, we rather anticipated a falling off as the season advanced. Each succeeding month, as shown by our monthly reports of building intelligence, has been of the most gratifying character, neither month of the year showing any marked decrease in the number of buildings commenced, while at present writing the outlook is excellent. Architects generally in San Francisco are busy, and new work still coming in. The special feature of the case is that the large amount of building improvements has been confined mainly to tenement and residence structures, but few large operations being commenced during the year. There have been very few even moderately large brick edifices reported during the past seven months, and none that we know of to be commenced at a very early day.

But in this line we look for considerable movement next year. We know of several brick structures which are very sure to be commenced within the next six months, and unless the high cost of building materials shall prevent it, there will be large activities in brick buildings before the end of 1884.

The numerous large purchases of real estate by our monied men, the buying up of desirable pieces all along the line of Market, below Montgomery Street, indicate the purposes of the future. It is not at all probable that business firms have invested in real estate purchases for speculative purposes; and of personal knowledge we state that many now holding desirable building lots intend to "build in the spring," which means as soon as the spirit moves them, and we know from what we have heard from the parties themselves that their spirits are wide awake, and likely to impel forward movements at any moment. All classes of mechanics are busy, and work goes slow in many instances, because of the impossibility to obtain the execution of mill, stair, plastering, and other portions of the work promptly, the general complaint being, "can't get the mill work," etc. Although, as we have stated, there are but few brick buildings under way, the entire force of journeymen brick-layers have been fully employed in the putting in of brick foundations, and other brick work incidental to the erection of frame buildings. And should there be the anticipated increase in new brick buildings, there is certain to be a great scarcity of brick-layers, with possible increase in wages. In many sections of the State and coast, there has been absolute want of good mechanics, and the offer of increased wages has not in many cases been sufficient inducement to draw men away from the city and home life, good pay and steady work being preferred to exclusion in more quiet and lifeless places with four bits per diem advance in wages.

A PUGET SOUND paper states that 10,000,000 feet of logs have been cut from 160 acres of land in Pacific County, W. T., and that 4,000,000 feet is the average of that amount of timbered lands.

GERMAN steel rail makers assert that the Gilchrist-Thomas process cheapens their rails from 30 to 40 per cent.

S. F. Chapter American Institute of Architects.

THE Chapter met in regular session October 5th, the President, John Wright, presiding.

The minutes of previous meeting were read and approved.

A delegation from the Masons and Builders' Association of San Francisco being in waiting, the regular order of business was suspended, for the purpose of affording the delegation, consisting of Messrs. Richardson, Cox, and Leibert, an opportunity to explain the object of their visit. Mr. Richardson, in behalf of himself and colleagues, laid before the Chapter the following resolution adopted by the Masons and Builders' Association, requesting that the Chapter give the subject matter of the resolution such consideration as its importance may warrant:—

HALL OF MASONS AND BUILDERS' ASSO. OF S. F.
314 Montgomery Street,
October 5, 1883.

To San Francisco Chapter,—American Institute of Architects:—

GENTLEMEN: At a regular meeting of the Masons and Builders' Association of San Francisco, held October 1, 1883, it was resolved that on and after January 1, 1884, we respectfully request you to segregate all work appertaining to the mason work from other contracts exceeding three hundred dollars, labor and material included.

ROBERT MITCHELL, President.

After the withdrawal of the delegation, the resolution submitted for consideration was received, and a committee consisting of Messrs. Macy, Welsh and Gash, appointed to report thereon at the next regular meeting of the Chapter.

A partial report from the committee appointed at the August session of the Chapter, to take into consideration and report upon the plumbing rules and regulations adopted by the Board of Health, was received and read, and after considerable debate thereon the matter was re-referred to the committee for further consideration, with Mr. Laver substituted as a member of the committee in place of Mr. Curlett, who is absent from the State.

Wm. Lee and M. G. Bugbee were elected student members, and Messrs. John Hall, R. C. Ball and W. Copeland proposed as fellows.

The President then read his annual address, which was listened to with marked attention, and received with applause and a vote of thanks. Its publication in the CALIFORNIA ARCHITECT AND BUILDING NEWS was ordered by vote of the Chapter.

The annual report of the Treasurer for the year ending September 1st was submitted, showing that all indebtedness had been liquidated, leaving a balance of cash on hand for future purposes.

Messrs. Laver, Henricksen, and Gash were elected Trustees for the current year.

Adjourned.

CHAPTER PROCEEDINGS IMPROPERLY REPORTED.

M. G. (not Sumner) Bugbee, as reported by the *Morning Call*, was elected a student member.

The *Chronicle's* report was full of errors. The suggested amendments to the plumbing rules and regulations read before the Chapter, was by a single member of the Committee and not by the Committee as a whole, nor a majority thereof, which was re-referred, with no disposition on the part of the Chapter to urge their adoption upon the Board of Health. All that about reducing the cost of plumbing 15 per cent., depriving the Inspector of present powers—the reflections cast upon the Inspector—"not knowing his own mind from one week to another,"—"his actions depending largely upon who had the job in hand"—thus insinuating partiality and favoritism, etc., etc., are decidedly unfair and unjust misstatements. Mr. Sweeney, the Plumbing Inspector, as a mechanic is too well informed not to understand all the necessities involved in proper plumbing work by the plumbing rules and regulations, and too intelligent and upright as a man to be swerved from a consistent and uniform course of action by personal favoritism.

Architectural Quackery.

THE following from the Detroit *Journal* is so thoroughly in harmony with the views repeatedly expressed in this journal upon the same subject, that we copy in full, regretting to learn that the architectural profession in Detroit is cursed with the same class of incubuses that have done so much to lower the standard of competency in those claiming to practice the great science of architecture in California; by pandering to the avarice and caprices of owners who permit themselves to be humbugged into engagements with men of exceedingly limited acquirements as practicing architects, and no thoroughly educated and scientific knowledge of the profession, simply because they offer their trashy services at rates which propose a saving, but which in practical results are far more costly to deluded owners than would be the services of competent men at the highest rates of commission.

"It would seem that the ancients, more freely than the moderns, understood and appreciated the dignity and importance of the profession of the architect. By the Greeks, the name 'architect' was originated, denoting literally 'a master workman,' and clearly implying not only the designer of public and private buildings, but a man versed in all the details of their construction, and competent himself to direct the workmen as they wrought. And we know, from the ancient writers, that this was the practice of the celebrated architects of antiquity, the men who in Egypt, Babylonia, and Greece, reared those wonderful structures, the ruins of which have won the respect and admiration of preceding ages. By the Greeks the architect of the Parthenon was honored as an artist of merit and fame equal to that of Zeuxis, the painter, or Phidias, the sculptor.

"The present utilitarian age by no means estimates the profession of the architect at its true rank. This is due to a number of different causes, foremost among which is the fact that it is not protected by any of those restrictions which serve somewhat to elevate and maintain the ranks of the professions of law and medicine. It is notorious that even in those vocations scores of incompetent men are each year, in every State, let loose upon society to work no end of mischief by their allied ignorance and presumption. How much more then must this be the case with the profession of the architect, unprotected as it is by legal enactments and open to the entrance of all those classes who, because they may profess some knowledge of building or have obtained a smattering of the science of designing, have the impudence to deem themselves, and to hold themselves out to the world, as fully competent architects and designers.

"The true architect is a man possessing an innate love and appreciation of the true, the beautiful and the grand in form; a taste which has been purified and enriched by years of study and communing with the most perfect of earth's buildings; a skill, the result of long and thorough study and constant practice and a practicality of mind which enables him to adapt old and recognized forms of beauty to the want and convenience of modern times. Such architects are to be found in considerable numbers in Great Britain, France, and Germany, where they are first thoroughly instructed and drilled in the great technical schools which exist in those countries, such instruction being further supplemented by years of careful study under some experienced architect.

"But how stands the case in America? Here a young man with little education and often with a lamentable deficiency of natural or those other qualifications which should be possessed by any aspirant to so important a profession, enters the office of any practicing architect, and studies for a year or two the designing of ordinary buildings and the drawing of plans, with hardly any acquisition of knowledge of details, of the materials employed in building or the builder's art. At a time when he is just beginning to understand the rudiments of his profession and would commence to investigate thoroughly its various departments, he rushes into the business world, and in a glaring sign announces himself to the public as a competent 'Architect and Superintendent.' The next step with this bold adventurer is to toot or drum for business, and with unblushing effrontery he makes a thorough exploration of the town or city in which he may reside and interviews every unlucky individual who may by any probability be likely to erect a building within the next five years. The principal and often the only argument that he can urge in favor of his employment is the cheapness with which he will do the job, thus degrading the standard of an honorable profession, and tending to bring into equal contempt with the community the true architect and the charlatan.

"The result is what might naturally be expected, buildings constructed with total lack of taste and with no regard to the fitness of things; designs copied bodily from some cheap book of plates and adopted with a serene contempt for all actual surroundings; matters of detail and of construction turned over entirely to the mason and carpenter, who work their own sweet will upon the building. The frequent result is a structure alike devoid of beauty and of utility, an edifice which is likely to stand for a considerable number of years, a fitting monument alike to the incapacity, want of taste and lack of skill of architect, builders, and proprietor.

"Not unfrequently the most serious accidents occur through the incompetency and carelessness of these mushroom architects; but the cheapness with which their services can be secured seems to be, to the general public, an attraction which no amount of reason or common sense is able to prevail against, and the grossest blunders, with results that cannot afterwards be remedied, are constantly to be found in pretentious and showy houses in Detroit and other large cities, where new buildings are being erected with wondrous rapidity, and which should form permanent additions to the beauty and attractions of the localities.

"It is not surprising, after these considerations, to learn that of all the army of so-called architects there are not more than five genuine architects and artists in this large metropolis, and that a great proportion of the vast amount of building annually done in Detroit is of such a character that it must, by a competent man, be pronounced a sham and a humbug, soon to demand repairs and alterations, never to satisfy the owner or tenants, and possessing as its chief merit a somewhat speedy perishability.

"For such a serious state of things, about which there unfortunately cannot be any doubt, there certainly should be some remedy, and it would seem to lie in the double but kindred discretion of a more enlightened public opinion which should bestow patronage more wisely, and of legislative action which should throw around the profession restrictions which would tend to elevate it and free it as far as possible from charlatans and pretenders.

"Very great delay, loss and litigation are frequently occasioned by the failure of incompetent or careless architects to prepare full and detailed plans of the buildings which they are employed to design. Owners and builders should, in all cases, be furnished with one full copy each, as in that event the work can be carried on completely according to the plans of the architect, and the owner, in case of any litigation arising, has in his hands the plans, the very best evidence, in conjunction with the specifications, of the architect's full designs, and of measurement, cost, etc. The plans for the workman to follow can hardly be too full or too much in detail. Such thoroughness on the part of the architect is an invaluable benefit to both owner and builder."

BUILDING NOTES.

From Lathrop to Los Angeles.

A trip has recently been made by our agent through the southern part of our State. His primary duty was the distributing of a portion of our supplement in every town upon the route. Not only was this duty faithfully performed, but scores of new subscribers were secured, and a full record of building improvements was noted.

Modesto.—Mr. R. McHenry is having erected a two-story and basement brick. It is building by days' work, at a cost of $25,000. Numerous small buildings and improvements are under way.

Merced—Can boast of a new Episcopal church. *A.*, Isaacs & Francis; *C.*, E. R. Francis; cost, $800. Two-story and basement frame; *O.*, J. H. Upton; *A.*, C. Beasley; days' work; $4,500. Two-story brick; *O.*, M. F. Moran; *C.*, W. H. Ford; cost, $15,000. Several small buildings are in process of construction.

Athlone.—The Southern Pacific Railroad Company is having erected a warehouse, at a cost of $2,000.

Fresno—Has grandly arisen from the effects of fires that laid low nearly all the business section of the town. In addition to buildings previously reported, we note the following: Methodist-Episcopal church; *C.*, P. M. Behunin; $2,000. Two-story and basement brick; *O.*, W. E. Gilmore; *C.*, F. Banta; $4,000. Mr. Banta has the following buildings in his charge: Two-story brick for Mr. Shelly, $5,000; two-story brick for Statham & Co., $9,400, one-story and basement brick for Alcese & Co., $5,800; two-story and basement brick for H. C. Warner, $4,000; one-story brick for Mr. Ryan, $1,000.

Fowler's Station.—The Southern Pacific Railroad Company is erecting a two-story frame; cost, $8,000.

Tulare.—Two-story frame for L. D. Murphy; *C.*, G. W. Palmer; $5,000. One-story brick for B. W. Janchins, $5,000. Three-story brick for J. Asher; *C.*, Bonner & Young; $2,500. One-story frame; *O.*, F. M. Schultz; $1,000. Mr. J. F. Kessing is erecting four one-story frame, at a cost of $10,000. Badicalupi are having built four one-story brick; *C.*, G. W. Palmer, $12,000.

Los Angeles.—Our agent remarks that "in the *new* part of the town every other building is *new*." The record, in addition to those previously reported in this journal, proves that Los Angeles is the most progressive building center in the State, San Francisco being its only rival. We omit the streets, as the list is so lengthy. The following are under the superintendence of Kysor & Morgan, architects: Two-story brick for Joseph Mullally; *C.*, Keelan & Grant; $6,500. One-story frame for Major Wicks; *C.*, Beville & Co.; $4,500. Two-story brick for John Schumacher; *C.*, Willard & Phillips; $2,400. Two-story brick for L. J. Hammond; *C.*, C. Handerson; $15,500. Two-story brick for J. Bryson; *C.*, Beville & Co.; $17,000 Two-story brick for Dr. Widney; *C.*, J. D. Campbell; $11,500. Two-story brick for Dr. Griffin; *C.*, A. M. Mackray; $1,954. Building on San Franco Estate; *C.*, O. Bonchamp; $15,500. Baptist church; *C.*, W. O. Burr; $21,000. Catholic college; *C.*, M. Fitzgerald; $26,000. One-story frame for Mr. Kerckhoff; days' work; $4,000. Two-story frame for Mrs. Scott; *C.*, R. B. Young; $5,500. Two-story frame for Mrs. McDougall; *C.*, — Hargitt; $11,000. Two-story frame for S. C. Hubbell; $12,000. Two-story frame for J. E. Webber; *C.*, J. E. Wood; $6,000. Double frame building for Mrs. Gorman; *C.*, Thos. Golding; $7,000. One-story frame for J. W. Hinton; *C.*, H. Rhea; $4,000. Two-story frame for Mr. Ducommun; *C.*, A. Biles; $8,000. Two-story frame for J. Mead; $2,800. Two-story frame for — Hickox; $2,000. Two-story frame for Dr. Ch. A. H. de Sigoethy; $4,500. One-story frame for W. F. Marshall; $3,500. Two-story frame for H. Rorick; $3,500. Two-story frame for D. Steavens; $5,500.—B. J. Reeve, architect, reports the following: Two-story brick; *O.*, A. Valla; *C.*, J. E. Wood; $40,000. Two-story brick; *O.*, J. Barnard; *C.*, W. O. Burr; $36,000. Four-story frame; *O.*, Mrs. Bumiller; $30,000. St. Paul's church; *C.*, Skinner & Shaplin; $25,000. Presbyterian church; *C.*, J. E. Wood; $7,300. Two-story frame: *O.*, J. Sendouse; *C.*, G. E. Scammen; $6,800. Two-story frame; *O.*, W. H. Barclay; *C.*, G. E. Scammen. One-story frame; *O.*, J. A. Taylor; *C.*, C. Handerson; $4,200 Two-story frame; *O.*, R. & N. C. Wilson; $9,000. Alterations; *O.*, J. Lacy; *C.*, Golden & Beauchamp; $3,200. One-story frame; *O.*, J. C. Kays; *C.*, G. E. Scammen; $2,400. Two-story brick, alterations to the Bishop's residence; *C.*, J. E. Wood; $2,600.—The following are scattering: A livery stable is being converted into a theatre; *O.*, Perry Bros.; *C.*, A. S. Mackay; $6,000. One-story frame for Mr. Gongeon; *A.*, John Hall; $2,000. Two and one-half-story frame for Fred. Dohs; *C.*, Chislom & McCall; Mrs. Romnae is having built a one-story frame, S. Broomer drawing the plans and superintending the work; $1,000. One-story frame; *O.*, W. R. Hasson; *C.*, R. S. Cox; $2,000. Three one-story frame; *O.*, Ward & Wilkerson; $3,300. Two-story frame; *O.*, Mr. Sholl; *C.*, John Sholl; $3,500. One-story brick warehouse; *O.*, Kerchoff & Cuzner; days' work; $3,500. Three-story frame planing-mill; *O.*, Kerchoff & Cuzner; $6,000.

A POPLAR tree was lately cut near Moulton, Ala., that measured 58 feet in circumference at the butt, was 150 feet long, and was expected to turn out 100,000 shingles.

Book Notice.

LIFE OF SIR WILLIAM E. LOGAN, K. T., LL.D., F. S. R. F. G. S. First Director of the Geological Survey of Canada. By BERNARD J. HARRINGTON, B. A., Ph D. With steel portrait and numerous woodcuts, New York: John Wiley & Sons, 15 Astor Place. 1883. Price $2. 50. 432 pages, octavo.

NEW YORK STREET ARCHITECTURE.

The Renaissance.

BY A. CURTIS BOND.

OUR illustration shows a building in course of erection on Broadway, to be occupied by a firm of Japanese-goods importers, and which has progressed now only so far as the first floor. It is constructed of brick, the pilasters of granite, and having a granite edging to the circular spaces in the wall. These round windows give a novel appearance to it that is one of its peculiar features. The style is a very uncertain Renaissance, built up more from the imagination of the architect than from any following of a particular school.

* * * * * *

In this universal disposition to return to the manner of construction of preceding generations and adapt their styles to our present changed circumstances and surroundings, we must ask ourselves whether or not the result is to be as satisfactory as might be secured by the exercise of the inventive genius toward an entirely new conception. We must recognize the existence in the human mind of two distinctive faculties—the imitative and the inventive—and although it appears to have become the fashion to exercise the former rather to the exclusion of the latter, too much care cannot be taken that from imitative it does not becomes servile, and every succeeding effort show a deterioration and a decline from its predecessor. The spirit of the detail may be there, and the minutæ may be perfect; but there will be an air of constraint that will detract seriously from its effect. Take, on the other hand, the encouragement and exercise of the faculty for invention; it presents a new and attractive feature from the oldest materials, and it converts stereotyped shapes into most pleasing forms.

I know this is a very old plaint, but it is a very good one, and it is called to my mind by reading a lecture recently delivered in London upon the subject of architectural revivals. The lecturer took the ground that our modern imitation had become positively imitation only, and as such was to be condemned. The difference, in a few words, between good and bad architecture is this: If a man has no clear and distinct idea to express—has a vague and shadowy desire to say something rather like what his neighbor has said, or a slight improvement upon that sentiment—there is very little chance that he will be able to express anything worth hearing, or that will, if transmitted, convey any intelligible and lasting idea to a generation coming after him.

* * * * * *

The new Produce Exchange is almost completed, and it promises to be one of the attractive features of lower New York. It looks out upon Bowling Green, from Beaver and Stone Streets. It is an immense square building, five stories in height, and having at one corner a square clock-tower, rising about sixty feet above the roof of the building proper. The architect has chosen a sober and plain front, looking more substantial than decorative, and

giving the impression of solidity. There are dwarf portices at the entrances, composed of eight square granite columns, placed against the walls in groups of two, and directly in front of these a similar number of round granite columns, highly polished. These sixteen columns have a particularly massive appearance, while they neither encroach upon the pavement nor take from the depth of the building. But the most noticeable feature, and that which distinguishes the structure from everything else about it, is the principle upon which the windows are set in the wall—being constructed within great arches, or indentations, springing from the second floor, and looking like immense and elongated gun-holes in a fortress. These arches, as is also the body of the structure, are in brick, and the arrangement is such that, unless one be almost at the very edge of the arch, it is impossible to see the window within; at a short or a long distance the window is entirely lost to sight, and the stupendous dent only is seen, as if some great force had driven back the bricks and left its impress upon the façade. The effect is peculiar, and not unpleasant. Between these arches are medallions, bearing the coat-of-arms of the States and many of the cities of the country, New York alone being omitted. An inscription over the side entrance reads, "New York Produce Exchange," whereat the daily papers have made many uncomplimentary allusions and comments, claiming that it is for a fact the *New York* Exchange—but why label it so? Are the builders afraid some one will kidnap it at night and cart it off to a rival town, that they must needs put the name of the village owning it upon its stone, on the same principle that they paint a steamer's name upon its small boats? They all claim that *The* Produce Exchange is sufficient.

Figure 1.

There is a peculiar interior decoration that possibly deserves notice. It is a frieze of animal heads, extending about the large room—boar, cow, and bull alternate with pig, ram, and ewe, while at each corner an immense buffalo head projects some ways from the wall. The heads are made of terra cotta, and are realistic in every particular. The buffalo heads are the only ones that would not be taken for the natural object itself.

* * * * * *

I saw a staircase recently which I think might interest some of your readers, and so I made a sketch of it, and a very small plan of its construction and details. It is unnecessary for me to say that the style is distinctively French, and is such as is ordinarily encountered in the Parisian dwelling-house, but very seldom seen here, excepting in public buildings; and yet it is an economizer of space, while it is at the same moment exceedingly attractive in its effect. In this particular instance, however, the staircase is quite large and pretentious, as economy of space seemed to be no object.

The constructive material is iron, the string-board is of that metal, and in two parts, bound together by the baluster-bolt, as will be described further on; the back of the steps is of iron, the balusters and hand-rail of oiled oak. From the ground to the first floor there are twenty-two rises; from the first to the second, twenty-eight steps, and the same number from

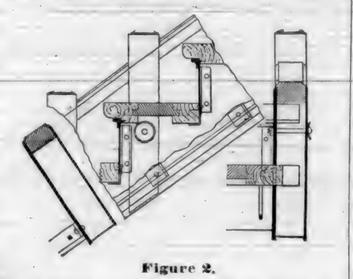

Figure 2.

the second to the third. Midway between the floors is a broader step, serving as a landing-place, or sort of lobby, at which is a window; or there might be a niche, if the window is not convenient. The lower step in this especial flight is five feet long, the following one is four feet and six inches, and so on until a quarter of the circle is reached (Figure 2), at which point the staircase has to take its normal width of four and one-quarter feet. The rises are paneled in oak and finished by a molding, as shown in Figures 3 and 4.

The string-boards being of iron, as I have said, are fastened together by a long bolt, which, beginning at the head of the baluster-post, extends through it and through two screw-holes in the iron plates, being held in place by the usual nut. The under part of the iron steps, that exposed to view, is plastered.

As will be noticed in the sketch (Fig. 1), the wall is wainscoted the entire length of the stairway, and at each floor is fixed a seat, for the relief of those whose errand may lie in the upper apartments.

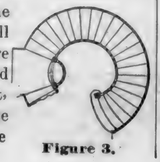

Figure 3.

The California Redwoods.

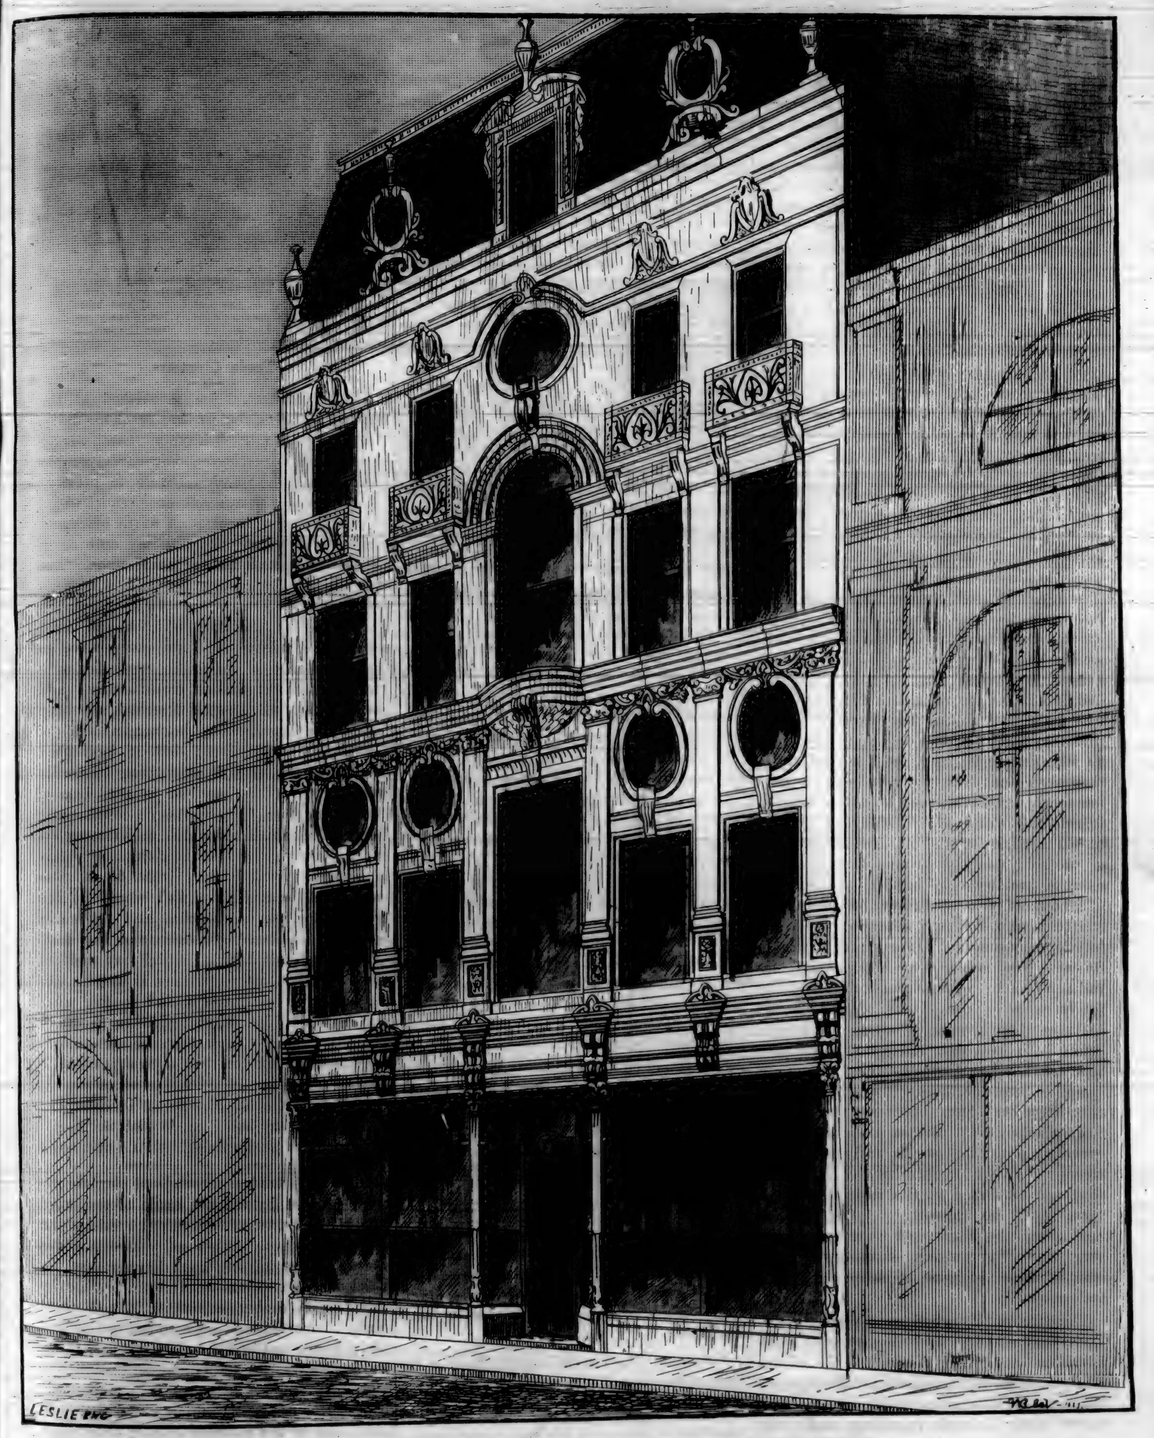
A CORRESPONDENT of the *Federal Australian* from San Francisco describes the cutting down of some of the great trees on the Pacific shore. He says:—

"It is a magnificent yet a painful sight to witness the operations in one of these redwood forests. You stand in the midst of vast trees, so close together that there is a dim religious light around you like that of a cathedral. This delusion is furthered by the apparent regularity with which many of these trees grow. You can look down a long aisle as if it were a groined arch of cathedral roof, and the only thing which undeceives you is, on looking up, far above your head, to see rifts of blue sky between the branches. But you are suddenly startled by a long cry of warning, which follows the rythmic chopping sound of the axe and the swish of the saw. It is the woodman, and his melancholy cry portends the fall of a mighty tree. There is a long and labored groaning sound; it is the tree breaking away from the friendly base which has held it, perhaps, for ages. Then there is a sharp "crack." The tree has snapped in twain. The mighty mass trembles slightly for a moment, then inclines in the direction toward which the practiced woodmen have designed it to fall. It topples—it falls. There is an awful crash—the falling tree is smiting the branches from a fellow tree which still stands upright, but not for long. There is a sound like a peal of thunder—the tree has struck the ground. The earth trembles for rods around, as if there were an earthquake; there is a cloud of dust, and all is over.

"The redwood is a most valuable kind of timber. It is very slow to burn, and if ignited is easily extinguished. It is very heavy and very dense in fiber, yet very easy to work, splitting with the most perfect accuracy, and yielding to the saw, the chisel, etc., with the utmost ease. When polished it makes a most handsome wood for interior fittings, and many of the finest houses in California are fitted with this wood in its polished state."

Mr. John Wright's Address.

WE direct special attention to the annual address of the President of S. F. Chapter of Architects, appearing in full in the present number of this journal, which contains many suggestions worthy of perusal and practical application. Students in the profession should feel specially interested, and show their appreciation of the efforts being made by Messrs. Wright, Saunders, Pissis, and other members of the Chapter, and by the Chapter as an organization, to provide courses of free instruction in the preliminary and advanced studies in architecture. Every gentleman practicing the profession upon this coast should unite with the Chapter, as by so doing each would derive a personal benefit from joining heartily in the Chapter work, and every student and draughtsman who will unite and co-operate with earnest purposes, will receive tenfold in return for all expended time and money.



A SKETCH IN THE RENAISSANCE STYLE OF ARCHITECTURE.

Want to Build Cheaply.

THE number of owners desiring to build cheaply, who do not start in with cheapness as a material factor, are the exception; the rule being to contemplate a building or buildings of certain size and character, and fixing the sum of intended expenditure from ten to fifty per cent. less than sufficient for the purpose. The very first thing sought to be impressed upon the mind of the architect is—that the outlay must not exceed a certain amount, although the improvement desired may reasonably be worth a much greater sum—if built in accordance with the prevailing demand for "good work," "first class," etc. If owners were more reasonable in their exactions, being willing to accept the only class of work possible under the restricted cost proposed, it would be all well enough; but the price is almost always fixed upon the basis of slop-shop, shoddy work, accompanied with—"*I want a good, substantial, well-built building*," and sometimes even a "first class structure." The inconsistency of the proposition amounts to ridiculousness. A customer who would approach a merchant or dealer in any class of goods, wares, or merchandise, and propose to buy salable articles in the regular way at less than cost of production, would receive but little if any attention, and perhaps the intimation that his custom was not desired. It is a very common thing for men who make ridiculously low offers for things that they would like to possess to be told to go where there is more need of iced water than overcoats. Yet it is equally as just and fair to ask a tailor to make a suit of clothes intrinsically worth $75 for $50, or a jeweler to sell a "first-class" time-piece at the value of the gold used in its manufacture, as to exact of architects and builders the erection of a house of a certain prescribed class and character, at a cost sufficient only for a far inferior construction. Owners have a right to fix the sum of outlay, but it is not fair for them to demand, in return, material and labor far in excess of such limits. And it is but little less than a business outrage for men to define both cost, size, and quality, and then reproach architects because they cannot accomplish impossibilities. If the instruction run: build me a house of certain size and accommodations for a certain amount, with no exactions as to the specific fittings, appointments and class of work, other than "the best that can be afforded for the stipulated sum," there would be consistency. But there is none when the limits and requirements diverge ten to fifty per cent.—a thing very common in the experience of competent architects generally.

The effect of this is bad, as it places architects who are honest and competent at a disadvantage, and greatly demoralizes the science of architecture in its technical and constructive features; and gives larger opportunities to the class of frauds operating under the name of architects, who are unworthy the name in any respectable sense, and who play upon owners' credulity with the deceit of cheapness, while, in fact, the latter is simply a sacrifice to misplaced confidence in men who do no more than others might do, if they would lower themselves to the same level of architectural botchery.

Bed-Rooms.

NO BED-ROOM should be sombre. Sanitary reasons underlie what seems to be merely a matter of preference. It is pretty well understood that dark wall-papers absorb not only light but infectious qualities in the atmosphere. On this score wall-paper is considered by the best medical authorities as objectionable, and rooms that have been repapered after having had in them contagious diseases, it has been found that years afterwards in removing the paper from the walls the germs have been sufficiently preserved to reproduce the infection. This, however, is a risk that is rarely run in private life. The papers that are now made for bed-rooms are so attractive that one may be well tempted to use them. What are known as the Morris designs—vines and flowers over surfaces broken by lattice-like bars—have been the suggestion for the greater number of the bed-room papers that are now produced. There is one advantage in these that is worth considering, and that is what is known as the repeat of the design is so dexterously concealed that in illness or nervousness they have not that element of torment that every one, who has had the misfortune of illness, can recall in the old-fashioned wall-papers.

Dados are not used in bed-rooms, but the frieze is of importance. Tinted walls are to be preferred even to artistic wall-papers. I have in mind a delicately tinted pink wall, with a deep frieze of wall-paper in luscious pink and cream roses on a gilt ground, with a small gilt molding between the field and frieze. Painted walls are cleaner, healthier, and every way to be preferred. Light tints are, of course, most desirable, and the woodwork, if painted, can carry out the same scheme. For example: The walls are of a faint pink; the frieze has a gilt molding, a deeper tinted pink band leading into the cove, which is faint pink and greenish-gray, separated by gilt lines; the ceiling is faint pink with a center ornamented in pink, gray, and gilt. The doors have their panels of pale pink with gilt molding; the sides and frames are greenish-gray.

This is simply a hasty sketch of one room. Deeper greenish-gray and red, olive and pink, turquoise or robin's-egg blue and greenish-gray, buff and scarlet are all tints that can be used together in the same way.— *Mary Gay Humphreys, in Decorator and Furnisher.*

THE price of logs in the neighborhood of Astoria, Oregon, has advanced from $5.00 to $6.00 a thousand.

All new subscribers for 1884 will receive the balance of this year free.

☞ Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas, send us a sketch of them and we will make the cuts.

Trade Circulars.

AS AN architect, I am astonished at the number of trade circulars that reach me daily. Nearly every post brings a batch—large sheets, small sheets, books, show-cards, pamphlets, and samples; and if I were to preserve all I receive for future reference (and I would like to) I should require an extra office and clerk for arranging them, to say nothing of the wall-space to hang the cards upon. The result is that the waste-paper basket receives by far the larger portion. This, to me, appears to be a great waste of cash, and must come out of the profits. I am quite alive to the importance of being in possession of a knowledge of the various manufactures, and carefully scan all circulars I receive, and keep large piles for reference, the accumulation of nigh upon forty years; but it has often occurred to me that if something like order were adopted by the senders, in the sizes of their documents, they would be much more likely to be saved, and much easier for reference. Suppose, for instance, that all documents were issued foolscap size, a file of these would not be unsightly, and would fit the ordinary foolscap receptacles, and references would be facilitated by turning over leaves all the same size, instead of which my shelf of trade circulars, although kept as well as can be, is a complete muddle, and to find what you require is like searching for a needle in a bundle of hay. As an instance, this morning's post brought me two documents, one a book 6 inches by 3½ inches, and another a sheet 3 feet 3 inches by 2 feet 2 inches. The question is what am I to do with them—for they are both worth saving? H. M. (BUILDER.)

"DEAL."—Readers of technical journals are often puzzled by the use made of the word "deal" by nearly all foreign publications, and some home ones. As generally used it means simply a piece of soft wood lumber; but the strict definition of the word, as understood by the English timber merchant, is, soft wood timber, imported, and sawn to the section of 9 x3 inches, or 8x4 inches, or 10x4 inches. Similarly "planks" are 12x3 inches or 12x4 inches, and "battens" 7x2½ inches, or 7x3 inches, all irrespective of length, which varies considerably, and of the country or port they come from.

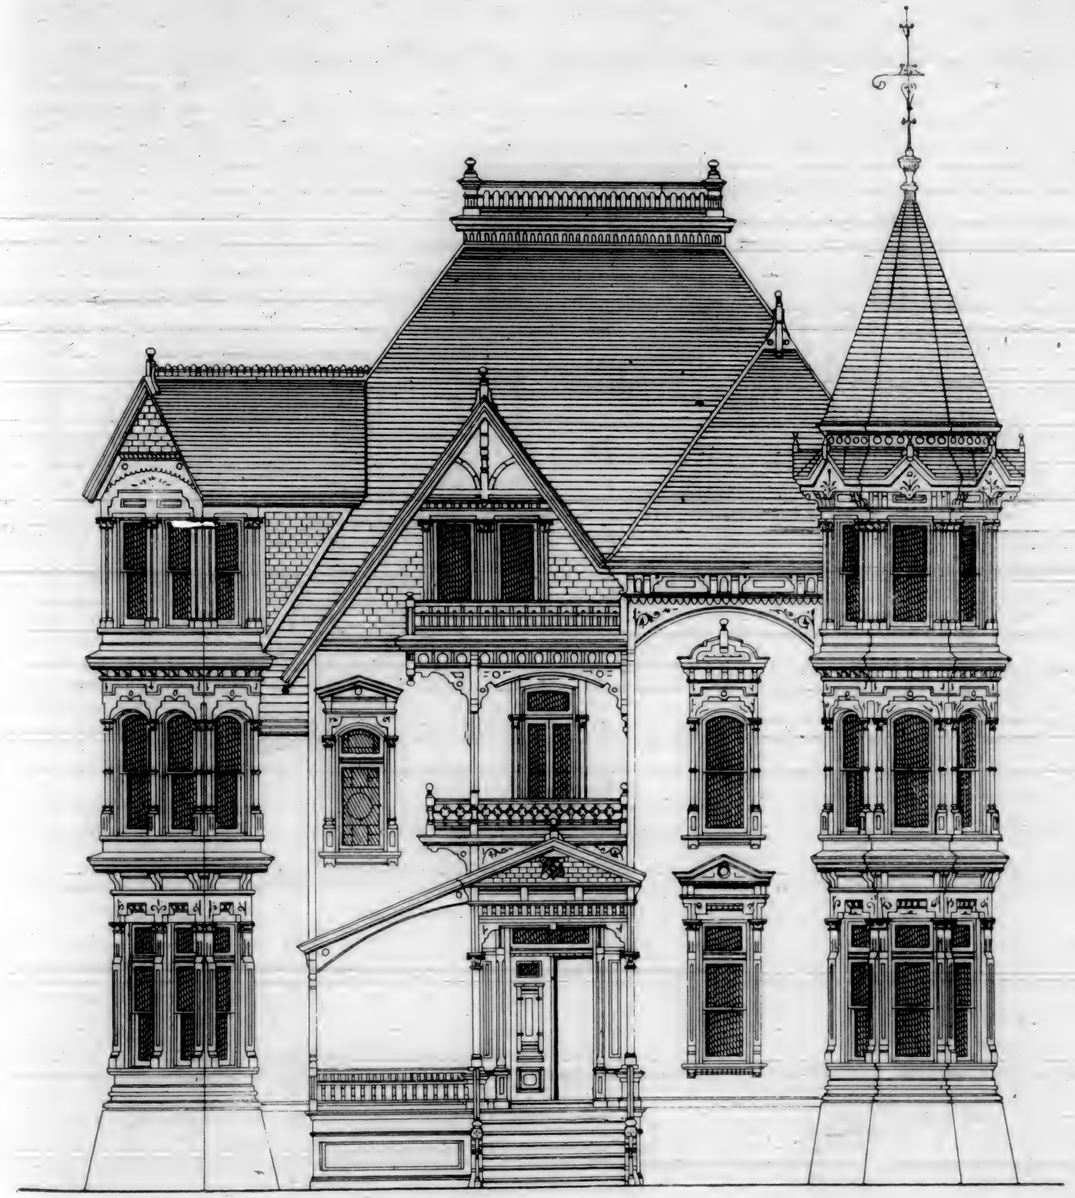


PLATE 2.—SUBURBAN RESIDENCE—COST FROM $12,000 TO $15,000.

We desire to have a uniform time for the commencement of all our subscriptions. In order to do this, we have credited those whose subscription commences in any month between July and January with the difference so their time will begin with the first month of the year. New subscribers will receive the remaining numbers of the year free of charge. All subscriptions must begin with either July or January.

American Institute of Architects.

A FULL report of the proceedings of the Institute, which commenced its seventeenth annual session at Providence (R. I.), on the 29th ult., has been forwarded to this journal, and we regret that lack of space precludes more than a brief mention of a few of the many prominent matters of interest brought forward during the several sittings. The following extracts will doubtless be read with interest by architects on the Pacific Coast:—

"The walls were hung with many fine specimens of architectural drawing, contributed by the members, one remarkable design being the outgrowth of a discussion held at the last annual meeting in Cincinnati, over the erection of a building in New York City for the Institute. The artist, with uncommon skill and nicety of finish, had combined all the architectural forms of ancient and modern schools in a massive and lofty structure, which commanded the admiration of all, in that it displayed a thorough and accurate knowledge of architectural science."

There is something pleasing to every intelligent architect in the above extract, as it touches the higher and finer chords of architectural thought and reflection, and presents suggestions far removed from the lesser order of things found in daily practice by architects in nearly all parts of the United States. There is so much of a demoralizing tendency practiced in the profession that incidents of the character quoted become refreshing to honorable men, who love the science of architecture as well for its intrinsic beauties and grandness, as for the profits flowing from its pursuit.—ED.

"The presiding officer of the Convention is Thos. U. Walter, LL.D., of Philadelphia, who ranks as the oldest member of the Institute by practice and years, and is a gentleman of dignified and imposing appearance. He commenced work at the drawing-board in 1829, furnished the plans for Girard College in 1833, and designed the wings and dome of the National Capitol in 1852, and for sixteen years was engaged in the perfection and completion of this master-piece of architectural art. Although advanced in years, he has a fine physique, and hale and hearty bearing, as the result of systematic exercise and daily application to his chosen art."

Would that one so worthy and able, and honorable in the profession, could live in the full enjoyment of all his physical and intellectual powers until the office-boys of the present day became gray-haired and old in following in his professional footsteps. The President's address contains much of stirring interest, closing as follows:—

"I take occasion to remark, in conclusion, that the unlimited freedom that characterizes the composition of architectural forms, at the present day, demands a far greater amount of study, and a higher degree of cultivation in the perception of the beautiful in art, than ever existed in the past.

"The simple and artistic forms of the Pagan world have yielded to the inspiration of a higher civilization. The fetters that held architectural forms to classic models for centuries have been broken, and the fact has become patent that progress is the life-blood of architecture.

"Mediæval art, glowing with the benign influences of Christianity, emancipated the processes of design from the trammels of formulated methods, and led to the subsequent development of the beautiful creations of the later Gothic school, which still claims our highest admiration, and our profoundest study.

"By tracing the mental processes by which the human mind has been led onward, from the first rude attempts of our race, to impress an artistic character on the art of building, up to the highest architectural developments of the present day, the student is prepared to abnegate all conventional trammels; and in view of the treasures of the past, laid at his feet by an exhaustive literature, he has acquired the habit of thinking for himself."

Reports of officers from numerous Chapters were received, all showing a healthful state of things generally, and an increasing interest in various sections of the country in Chapter work. New Chapters are being formed in many places not heretofore represented in the parent body. As a matter of local interest, we quote:—

"The San Francisco Chapter reported that it was progressing finely, having 41 members, with an average attendance during the year of 14; that it was clear of indebtedness, with a splendid set of books, etc.; and that it recommended that a regular time of holding the Convention should be adopted, so that the Chapter away off on the golden western shore might contribute to the body, that its 'good works may be seen of men.'"

It is with pride and pleasure that we refer to our home branch of the Institute, which in membership is about equal to, if not the largest, of any Chapter in the Union. And if the few worthy men in the profession who have thus far failed to unite with the Chapter would master their disinclinations and become Fellows, San Francisco Chapter would, beyond question, assume first position numerically.

A paper was read by Prof. G. Lanza, of the Institute of Technology, Boston, on "The Strength of Materials from Actual Tests;" also one by John A. Fox, F.A.I.A., of Boston, which "dealt in frequent and vigorous denunciations of 'architectural competitions.'" We will give its full text in our next issue.

ELECTION OF OFFICERS.

The Committee on Nominations presented the following list of officers, who were unanimously elected:—

President—T. U. Walker.
Treasurer—O. P. Hatfield.
Secretary—G. C. Mason, Jr.
Board of Trustees, ex officio—H. M. Congdon, A. J. Bloor, E. T. Littell, Napoleon Le Brun.
Committee on Publication—H. H. Holly, Charles Crapsey, T. M. Clark, J. McArthur, Jr., G. C. Mason, Jr.
Committee on Education—Prof. W. R. Ware, N. Clifford Ricker, Henry Van Brunt, Alfred Stone, Wm. A. Potter.
Secretary for Foreign Correspondence—T. M. Clark.

President Walter, in accepting the position, thanked the Convention for the honor. He was sorry that he had not made himself more useful, but the wide distances between the Chapters made it almost impossible to meet the members but once a year. Heretofore he had done the best he could to further the interests of the Institute, and hereafter he would continue to do the same. He would accept the office with many thanks. [Applause.]

Mr. T. M. Clark, of Boston, read a very ably-prepared paper, upon "The Architect as a Sanitarian," from which we take only the opening sentence:—

"Not long ago a plumber, in describing to me the difficulties under which he, in common with the better class of his brethren, labors in competing for the work which architects have to give them, said that he had just come from an office in which the proprietor had been expressing the opinion that 'this fuss about plumbing and drainage was all humbug;' that 'people used to live as long without it as we do now,' and that he 'didn't think there was anything in it.' Probably this individual is not the only one of his kind, and it is well worth considering whether the 'fuss' that some of us are in the habit of making about what we may call the organs of excretion in our buildings, is a proper and necessary part of our professional service to our clients, or merely the indulgence of a diseased appetite for novelty, to be gratified at our clients' expense. I trust there are not many among us who hold the latter view."

We should like to copy in full, but space will not permit in this issue.

Very many other matters of interest were presented, discussed, and enjoyed, and the Convention adjourned, with a recommendation that the Trustees, in whose hands the selection of places of meeting is reposed, select Albany, N. Y., for the next annual session of the Institute.

Paper Mill Directory.

WE have received from the publishers, C. W. Bryan & Co., a copy of the above directory. From it we find that there are 4,463 paper and pulp mills in the world, of which number 1,099, or nearly one-fourth, are in the United States. There are eight mills in this State, the largest of which are those of the California Paper Company. The only kinds manufactured here are news and wrapping paper. The work is very handy for those interested, and is sold at the low price of $1.00.

Modern Architectural Designs and Details.

WE have just received a large number of this work. We regard it as one of the best books issued for architects and contractors. Sent post-paid to any address, upon receipt of $10.00.

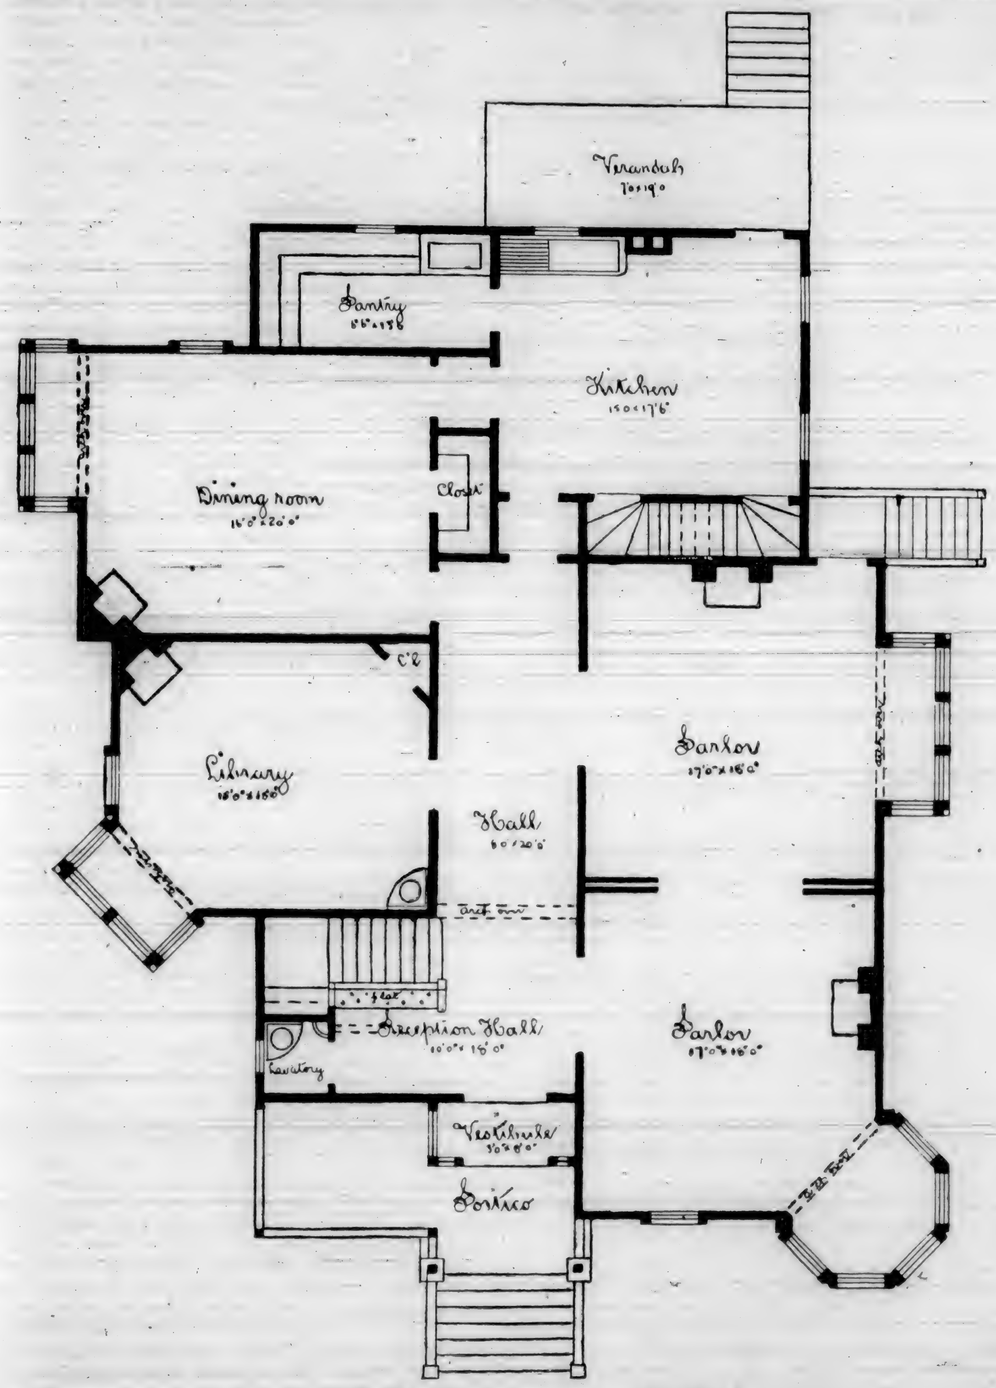

PLATE 3.—FIRST FLOOR PLAN OF SUBURBAN RESIDENCE.

The Annual Address

Delivered Before the San Francisco Chapter of the American Institute of Architects, by the President, John Wright, F. A. I. A.

FELLOWS AND ASSOCIATES:—Conforming to what appears to be an established rule, that the newly-elected President shall open the proceedings for the forthcoming year by delivering an address, it falls to my lot once more to invite your attention to a few remarks, suggested by the occasion which has called us together.

I heartily congratulate you on the recurrence of these opportunities for friendly intercourse and mutual help—opportunities, it would seem, which we ought to hail with peculiar satisfaction, inasmuch as they not only open the way to all that is desirable in the way of professional association for its own sake, but it enables us, by taking a general review of the past year's work, to forecast the future, and with renewed hope and fresh encouragement to press forward in the prosecution of the important objects which the Chapter proposes to accomplish. It also enables us to promote, as a Chapter, as far as in us lies, those general projects for the good of the Institute at large which are at the present time engaging its attention. I would, therefore, in the first place, ask you to follow me in a brief review of those matters of more immediate interest to ourselves which have occupied our attention hitherto, and which we hope to develop in greater fullness in the future.

As will be seen by the Secretary's report, the number of members, consisting of Fellows, Associates, and Draughtsmen, is 41; but while our monthly meetings have been regularly maintained, the attendance at the meetings has not always been satisfactory. This may be owing, however, to the era of business prosperity with which the past year opened, and which may have interfered with the Chapter's sessions to some extent.

Several papers, on subjects of considerable interest, have been read during the year; and were this feature developed as it might be, greatly increased interest in the meetings would doubtless ensue. In this connection, I would suggest that, by pre-arrangement, promises of papers on special subjects might be obtained from different members of the Chapter, to be read on certain fixed occasions, according to their convenience. Were the titles of these subjects published beforehand, they would probably attract a greater number to the meetings, and at the same time much useful information would be gathered, and still others incited to aid in the good work. The abundance of material, and the varied nature of the almost universal knowledge needed in the theory and practice of architecture, renders selection easy, so that each may have an entire department to himself, without the least fear of having his chosen domain invaded.

I will now revert to a subject which has occupied a considerable share of our time and attention during the past twelve months, namely:—

THE STUDENTS' CLASSES.

In alluding to this subject, I shall be compelled to refer you to the latter part of the address delivered by me before this Chapter a year ago, wherein three propositions were made, embodying a scheme for the gradual establishment of a sort of "Technical School of Architecture," the first of which was that free classes should be established for the articled pupils of the members of this Chapter; second, that a system of competitions amongst said students should be inaugurated; third, that a traveling studentship should be founded by the Chapter, and that a student should be selected by competition to receive the benefit of the studentship, at the end of three years. This scheme was, after due consideration, adopted as the basis of future operations, and the first proposition has been virtually put into effect.

Three classes have been established—one in practical architecture, one in free-hand drawing, and one in modeling, and have been in regular session for several months.

With the present Chapter year a mathematical class will be inaugurated, and as soon as proper arrangements can be made, a carving class will be put in operation—thus combining something practical with theoretical instruction, and so relieving the monotony of study by a delightful variation of real work.

It is also hoped that during the present year a proper course of reading may be laid out, and an effort made in the direction of a systematic series of competitions.

A class in construction is very much needed, and it is suggested that occasional Saturday afternoon visits be paid by the classes, under the direction of volunteer conductors, to some particular building in course of construction, or to some planing-mill or machine-shop, or to the rolling-mill or the glass-works, or wherever useful information may be gathered and practical ideas obtained, so as to supplement theory by an inspection and familiarity with the practical, on every possible occasion.

We do not hope to accomplish more than the above at the present time. Were our means greater, our progress would be faster. By the Treasurer's report, however, it may be seen that we are out of debt, and that we have a balance in his hands. Still, our progress must necessarily be slow. Time, as well as means, is necessary in the training of the young men, whose available leisure seems to be, even now, very much absorbed in their arduous though interesting studies.

The third and final proposition, embracing the founding of a traveling studentship, though still in abeyance, we hope to accomplish in due time. It has been suggested that the funds arising from life memberships should be devoted to this end.

It must not be forgotten, however, that there are many other important objects, which, to insure our success as a Chapter, must in due time receive our careful attention—the procurement, at an early day, of a suitable room for meetings, classes, etc.; the formation of a library; the collection of materials for an architectural museum—all matters of most essential necessity, if our school is really to progress and prosper.

It must be remembered that without progress prosperity is impossible. As soon as the tree ceases to grow, it begins to die; and so it will be with ourselves. But there is growth of more than one kind. Growth in numbers is not the most important kind of growth, although what will conduce to that end in a healthy way is worthy of the most careful consideration. Growth in associated effectiveness is a growth of a better kind, and still more indispensable; and growth in individual excellence is a matter of the very highest importance, since the perfection of the whole body depends on that of each member. And here let me say that we must not allow ourselves to be daunted by the greatness of the task before us, either as individuals or as a body.

One thing that we may feel assured of is that true earnestness in these, the most worthy objects to which it is possible we can devote ourselves, will unfailingly meet with its due reward, not only in the confidence of a public which never fails to ultimately distinguish the true and disinterested from the false and selfish effort, but in the ultimate countenance and co-operation of many of those who, while they have proved themselves most worthy members of our profession, still look askance at our efforts, as though they were unworthy of their regard. We must prove, however, by acts, not words, our unyielding determination to succeed, and ultimate success is a foregone conclusion.

It is true that there are many difficulties to overcome. In other countries, the work we are striving to accomplish is undertaken by the Government. Italy, Germany, and France support extensive and elaborate establishments, furnished with every necessary appliance and help. The school of fine arts in Paris is rightly estimated to be the best in the world, and had under its care last year 270 painters, 190 sculptors, and 570 architectural students, and is supported by an annual subsidy of $60,000.

Its museum contains the choicest examples of architecture and sculpture, constructive and decorative, from every quarter of the world, and in every known style, and is constantly increasing its collection. A course of study in this school is the recognized mode of training adopted by French architects. The student passes through an elaborate and systematic course of study, under competent professors. The French Government not only brings up he young architects in the way it thinks they ought to go, but when they commence life on their own account, it regulates them by a stringent set of rules, rigidly enforced.

In this country, however, the Government does not assume to foster its children with the paternal solicitude of older countries inured to

[Continued on Page 170]

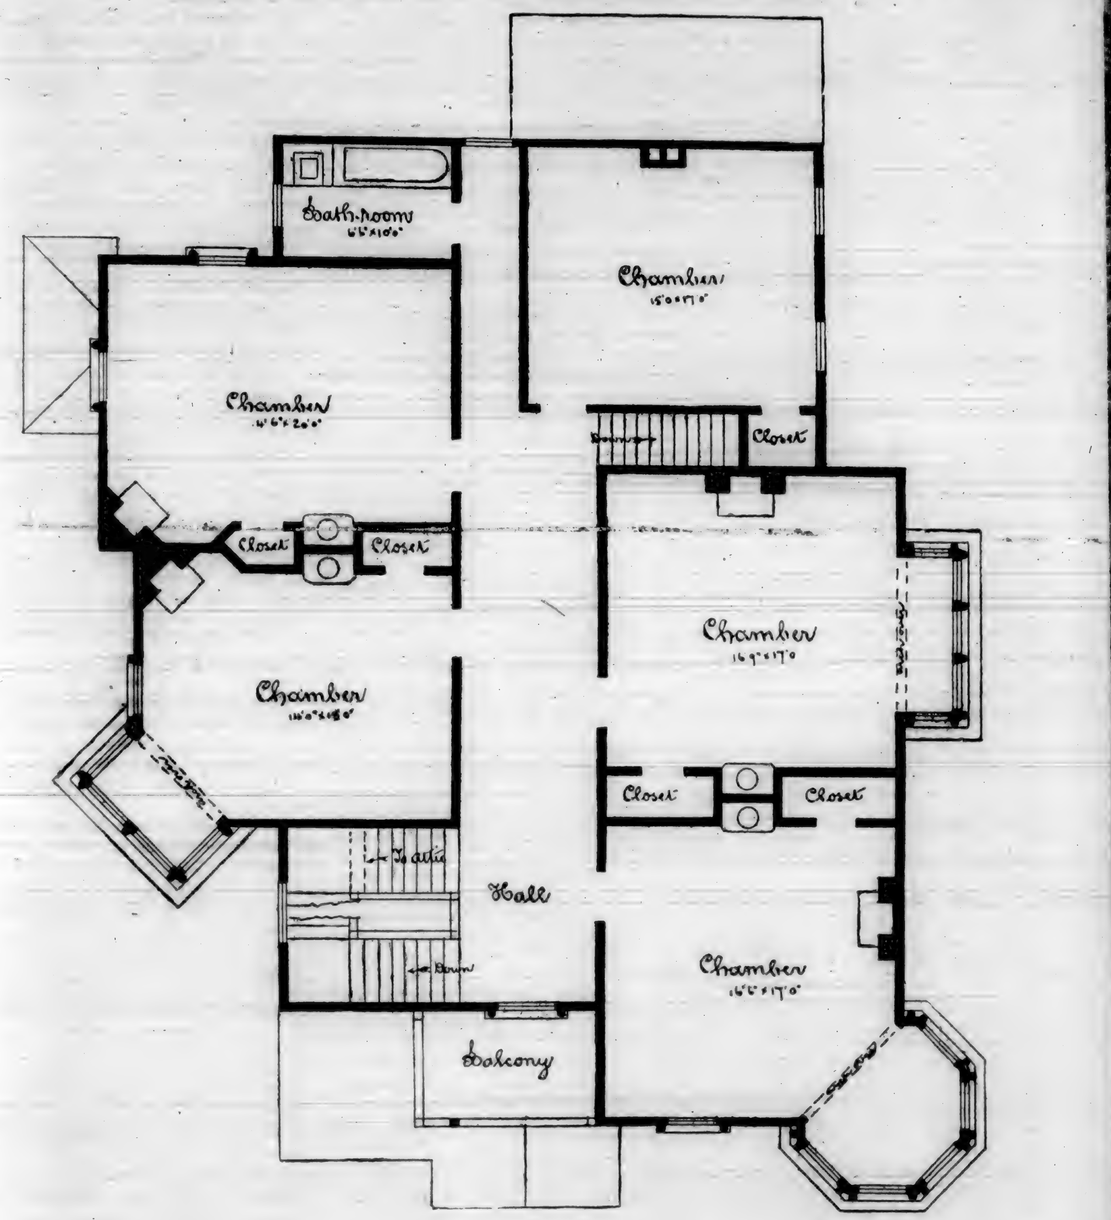

PLATE 4.—SECOND FLOOR PLAN OF SUBURBAN RESIDENCE.

We have just received a large number of Modern Architectural Designs and Details. This work should be in the possession of every Architect, Contractor, and Builder. Price—post paid—$10.00.

[*Continued from Page 168.*]

the usages of monarchial methods, but ever leaves them to pursue their own predilections in freedom. And there is no doubt much wisdom in the method, for though at the present time, as regards architecture, at least, there has hitherto reigned only the negation of order, the wonderful tendencies of free institutions to ultimately settle by a sort of natural selection into appropriate forms of order and of law, encourages us to hope that, through mutual co-operation and a broad and fraternal feeling pervading our Institute as a whole, and each Chapter in particular, some system may in time be evolved which shall regulate and control by force of sentiment, rather than of law, the principles and practice of all our members.

As regards the question of professional education in general, a factor of such great importance to our national progress in the practice of our art, a few words may not be out of place.

There are in this country at least three recognized schools in which architecture is taught by theoretical as well as practical methods. The Illinois University, Columbia College, in New York, and the Institute of Technology at Boston, all afford, in varying measure, courses of instruction in architecture in which, apparently, very complete systems of study are provided. It is needless to say that the humble and as yet very incomplete attempt this Chapter has inaugurated is not intended even as a substitute for such a course as is above alluded to.

It is merely such a course as we are enabled to carry out without expense to the pupils, and without compensation to the teachers, unless it be the satisfaction they feel at being enabled in some measure to supply, by a practical effort, some of the many disabilities of our isolated position. And now a few words to the students in the language of an English architect of eminence:—

"After our Creator's glory and our country's service, nothing so surely claims our greatest energies, and our whole capacity, as our chosen calling in life, not only as an effort to earn our daily bread, but because whatever so necessarily absorbs the greatest share of our time and strength, both of mind and body, should at least be done nobly and well."

It is excusable, perhaps, for those who are compelled to toil in an endless round of monotonous and uncongenial employment, to seek in amusement some relaxation from the tedium of their life, though even the meanest and most repellant of callings may be lightened by the magic influence of a hearty good-will, and rightly viewed may even be engaged in with satisfaction if not delight.

But to the architect who has not mistaken his vocation, what can be more delightful than the ever-varying, always-inspiring aspect of the glorious Queen of the Arts—Architecture.

"How she calls into equable play all the faculties of mind and body. At once sedentary and active, speculative and practical, artistic and business-like, the architect must combine the most opposite qualities, can make useful the most varied tastes, and can turn to profit the most comprehensive information; nor should we deem anything whatever in the whole domain of science and history foreign to or useless in his studies."

With a field before him far wider than the most exalted faculties, the most untiring energy, and the most prolonged life can fully improve, the architect may yet remember with satisfaction that to the untiring assaults of an unyielding determination to excel, there is nothing in the whole realm of knowledge, and of art, that is necessarily beyond the reach of his attainment.

One at a time the rounds of the ladder of life may be mounted, and the faithful climber, who always looks up, and never looks back but to gain encouragement to mount still higher, though he may never attain the pinnacle of his desires, will soon be surprised at the vast horizon which opens to his views. And he will, while glorying in the progress he has made, be ever ready to lend a helping hand to the brother on the round below, and can afford to regard with generous pleasure and admiration the progress of his fellow on the round above.

These and similar considerations furnish an incentive to the young architect to study and to labor with diligence and zeal; for although absolute perfection within even the narrow limits of one profession be unattainable to man below, at least the basis may be laid, and an advance made by the earnest worker towards, not only a useful life in this world in his chosen path, but for an eternity of development of perhaps undreamed-of faculties, of wisdom, and of goodness, in that realm of life beyond the natural, to which, in various ways, and wide-diverging forms of belief, we all look forward.

It now remains to close with a few brief remarks on the objects and interests of the American Institute of Architects, as recorded in the proceedings of the Sixteenth Annual Convention, held in Cincinnati, Ohio, October 25, 1882.

The chief subjects of interest there recorded were, first: a motion to enlarge the fellowship of the Institute. A recommendation to that end was made by the committee having the same in charge, and mailed to each member of the Institute, together with a series of consequent changes proposed to be made in the by-laws of the parent body. These changes are made with a view to throw all necessary safeguards around the admission of fit and competent persons, and appears to be carefully drawn, and conceived in a critical though liberal spirit.

The idea of an examination of candidates would seem to be relinquished as impracticable, and, indeed, under the free institutions and broad constitution of the United States such a plan is not likely to be more successful than in medicine, where the quack and the charlatan too frequently carry off the lion's share of patronage—at least, that of the ignorant and credulous.

The "voluntary examination" plan seems never as yet to have been brought to a successful issue. Were, however, the examinations made governmental and compulsory, as in law and education, the result might be different; but no private body could hope to command such an authority as to preclude the unauthorized practice of pretenders.

The most liberal course in this matter seems likely on the whole to attain the largest measure of success, the true guarantee to which will remain with each individual member after all.

The next question is germain to the last mentioned, and embraces the idea of a truly American Institute which embraces the dominion of Canada within its bounds. This seems worthy of the approval of all, and is of good augury for us too, for we have British Columbia to the north and Mexico to the south, both of which regions are in the line of great developments in the near future.

Another matter which has been touched upon is one with which we can surely sympathize. It is the idea that the Institute shall assist in the matter of traveling studentships. This is a step in the right direction, and will lead, we think, to the ultimate development of one of the most useful functions of the parent body.

Another and final question of interest is the ultimate erection of a home for the Institute.

At the convention of 1882 it was proposed that a general competition should be invited, requesting designs from architects throughout the country, with the suggestion that the development of a "national style" should be the object aimed at. Under the circumstances, the suggestion is worthy of careful consideration.

It would seem, however, that the earnest and honest effort of each of us to develop to his utmost the truest and purest principles within his knowledge, modified and controlled by the climatic peculiarities and physical surrounding of each portion of our wide-spreading land, whether tropic, temperate or arctic, mountain or plain, is the course most likely to result in a realization of what may justly claim to be called a truly American style.

PAINTED woodwork may be classed among the necessary evils of house decoration. No one in his sober senses will put paint on good woodwork if he can get an equal effect by the use of natural wood. But the costliness of all hardwood, and especially the expense of working it, renders the use of pine practicably inevitable.

A CORRESPONDENT writing from Pierre, Dakota, says that collections are made when the lumber is on the wagon. This is necessary for the safety of a dealer in a new country, as the people are strangers to each other, and no doubt many a dealer wishes the same custom was prevalent in older sections.—*Lumberman.*

Steel Square and Its Uses. Price $1.00.

The Foreman.

THE position of foreman of a shop or boss of a gang of workmen demands as its object the turning out of a fair amount of good work. Some fill one portion of this demand and others the other portion, but it is only the manager of men who fills both.

Employers are sometimes at fault in demanding from foremen the largest possible amount of work in a given time, always prodding and pushing, grumbling because a job occupied more time than they expected, and picking up every trifling interruption as a deliberate attempt at imposition. If a foreman is honorable and sensitive he will not bear this nagging, and so in shops ruled by such a proprietor changes of foremen are frequent. One such instance occurs to mind, just now, of a proprietor of a very thriving business, requiring the services of nearly a hundred good workmen besides apprentices, who had lost three foremen within two years either by resignation or dismissal. "Can you recommend a good foreman?" he inquired. "You have an excellent man for the place now in your shop," was answered, naming him. "Oh, he'll never do, he's one of the men himself. I don't want a man who is familiar with the workmen; I want a driver, and he ought to be a stranger." The position of foreman in that establishment is periodically vacant, and a stranger who can bring fair recommendations and has the qualifications of a "driver" can generally have assurances of a position, even if he has to wait a short time for his predecessor's shoes. And yet, this proprietor is in no usual sense "a hard man;" he simply has a wrong idea of the duty of a foreman. His ideal foreman is a mechanical blusterer who stirs up cyclones in the shop, produces an atmosphere of general uneasiness, and "makes the men hop round lively," as he once remarked. The workmen make trouble for every new foreman, and his "life is not a happy one."

There are, however, some foremen who are instructors rather than managers of men. Under their rule more time is spent in the details of work, in correcting errors, in "doing over," than should be required to complete the job. The scrap heap under their management grows to enormous proportions; every slight error in work and every slight mistake in apprehension of an order makes another accretion to the growing pile. Under such foremen the workmen never learn economy of time or of material.

A truly capacitated foreman is a possibility, and his portrait is drawn from no fancy sketch. In the establishment where he is a manager a strike has not occurred since it had an existence—twenty-five years. Probably there are many like him, and his portrait may stand for those of others.

Although he is generally as exact as the workmen to the "bell hour," there is no stir among them if he is late and no letting down of attention when he goes out. He assumes a part of every job and does it, wearing his honorable overalls like his men. He is not afraid of a loss of dignity or a relaxation of authority by addressing his men familiarly. He suffers no diminution of well-earned superiority in asking advice of some of his more experienced men. If one of his men "runs against a snag," he goes at once to his foreman, who either knows what to do, or has some proper and timely suggestion to make. He contrives to have his men interested in the work from incipiency to finish, and when one of them shows hearty interest in the work and turns out a good job, he is told of it in plain words that cheer his heart, instead of being rewarded with a grumpy "That'll do."—*Scientific American.*

The Mission Street Railroad, San Francisco, Cal., to Run Cars by Electricity.

THE Mission Street Railroad is about to experiment with electricity as a motive power on their road, and in the course of about a week a car will be run by the new power. Advantage has been taken of the discovery of Faure, the French scientist, with regard to the capacity of electricity for storage. To each car will be attached a dynamo machine, which is usually made use of in the generation of electricity. The machine consists of a cylinder which, being made to revolve rapidly in front of magnets, generates electricity, which is conducted off for use by wires. But the machine can also be used in another way, the process being reversed. If electricity is fed to the machine through the wires, the cylinder revolves. In the first instance, power is converted into electricity, and in the latter electricity is converted into power. The dynamo can thus be used by means of suitable attachments, to give motion to the wheels of a car, the electricity which is fed to it being kept in storage batteries, which occupy but a small space. These batteries are charged at the engine-house, where a steam engine is made to run a dynamo, which generates the electricity.

That cars can be moved by the means described there is little doubt.—*Electrical Review.*

A MECHANICAL writer says: "The best workmen I have ever known in machine shops are those who give a little attention after stopping time, just as a good groom takes the best care of his horse when it is the hardest worked, seeing that it is cared for before he gets his own supper. The result in the one case is that the horse is always fresh and ready for hard work, while the machine is always turning off a good quantity and a good quality of work."

Should this Journal be received by any subscriber who does not want it or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

School House and Church Architecture. Price $4.00.

The Present Place of the Plumber.

THE part which plumbers' work has to do in practical sanitation can hardly be overestimated, and yet to a considerable extent it may easily be overlooked. Indeed, it is mostly invisible, it is covered up in our walls, in our ceilings, or under our floors. Hardly anywhere is a pipe to be seen, the object being to keep as much out of sight as possible. Yet it is through these hidden pipes that both water and waste are carried through our houses; even into our sleeping rooms, where during our unconscious hours we are especially liable to be poisoned by noxious gases, and all these water pipes and waste pipes are unavoidably connected more or less closely with the drains, that we all know are vast reservoirs of noxious gases of decomposition, which, if not guarded against, will rise from beneath into our dwellings flooding every room with the breath of the plague. We have new-fangled names for apparatus, and elaborate statements regarding systems which are certainly calculated to mystify, and perhaps are sometimes designed to mislead, rather than to render clear the very simple fact that good material and good craftsmanship are alone needed to secure adequate water service within the house, and make such connections with the main drainage as to effectually prevent offensive smells and the escape of sewer gas into the house, which are the chief objects of the plumbers' art. Cheap work—so-called—really the dearest of all work, inferior craftsmanship and the semi-scientific theories of inferior or untrustworthy architects, self-elected sanitary engineers, and other persons who *think* things rather than *know* them, are, I am convinced, at the root of all that is now found defective in the plumbing as well as other bad arrangements in our houses.

It is common to denounce speculative—or as they are called—jerry builders; but, may I be allowed to suggest that, if there were no jerry public there would be no jerry builders? Simplicity of terms as well as of treatment will do more, I think, than anything else can to obtain that reform which the National Health Society and other sanitary associations are demanding in the interests of public health and comfort. These I know are but elementary truths, yet I venture to impress them in the strongest manner upon the attention of this assembly, because my experience tells me that it is from the violation of the first principles of soundness that the public suffer the evils they do from bad plumbers' work in their houses.—*Mr. Shaw to the National Health Society of England.*

PLEASE NOTICE.

The 75-cent edition of the Steel Square and its Uses is OUT OF PRINT. We cannot supply any more, as we have received notice from the publishers that their stock of that edition is completely exhausted. We have a number of the new and enlarged edition, which we will mail direct to any address upon receipt of

ONE DOLLAR.

This edition contains 30 more pages than the first one issued.

Management of Burned Forests.

AT the Forestry Congress in St. Paul, a paper by B. E. Vernon was read on this subject. In the management of a burnt forest, the essayist showed it is necessary to study the influence of the fire on the soil and on the standing timber before deciding upon the treatment. The vitality of the timber left standing may be injured by the scorching flames. In hardwood forests where the reproduction is expected from the stocks, as in the coppice, the reproductive power is injured in proportion to the degree of heat developed by the fire. In pineries, where reproduction can only be expected from the seed, the young seedling falls the first victim to the merciless fire. When the fire kills its original growth or causes its speedy death, the conditions of forest growth are at once changed and those alternations of species occur which are the natural consequences of the change of their conditions. The essayist went on to show how, in the case of a destroyed pine forest, the light-seeded species first takes the place of the old growth. Gradually, however, acorns and nuts will be deposited in the shade of the new growth, and as the light-seeded trees die off, the more valuable trees get a chance to grow, and gradually occupy the lands. This new forest of hardwood trees if protected by fire will long occupy the ground, but the original pine forest will not appear again until the land, long enriched by an annual deposit of leaves, has been again stripped of its trees and mellowed by years of cultivation. The forest fire, then, which destroyed the original pine forest, also destroyed the capacity of the land to reproduce a similar crop of trees for a period which may be set down at from 50 to 100 years.

The essayist showed from this the importance of protecting the forests by dividing them into blocks, for instance, by means of avenues from two to six rods in width. Where the risk of fire is caused by the proximity of a railroad, safety belts along the endangered line are recommended. Where forests have been partially destroyed, various measures are recommended according to the character of the forest. Where the destruction of heavy timber is a total one, the wisest plan is the immediate replanting of the land. Dead trees should not be allowed to remain, as they form the very best opportunities for the development of injurious insects. In forests of deciduous trees, where the heat generally is not as intense as in pine woods, it may be a cheap plan to await a new growth from the stocks and carefully nurse the more valuable species, in time filling up the bare spaces by planting shade-enduring species. In this, as in every other problem of forestry, it is impossible to prescribe any definite rules that will cover all the requirements of particular cases. A thorough elementary knowledge of the conditions of forest growth alone will enable the forester to decide what methods to adopt for the restoration of lost growths and reparation of the damage inflicted by fires on the soil and the forest.—*Lumber World.*

Common Defects in the Sanitary Arrangement of Houses.

THE best plan in the examination of a house is to begin at the top of it, and so we will begin examining a house from the roof, proceeding downward, and in our way I will point out the different mistakes that are likely to be made in the sanitary arrangements in various parts of the house.

The first thing which we must consider is that we have to get rid of the water that falls on the roof. The water from the gutter in front of the house may be disposed of in one of several ways. It may be conducted by a pipe outside of the house down the front into the area; or it may be conducted by a gutter through the roof, or, perhaps, through one of the rooms in the upper story into a gutter, over the middle of the house, between two parts of the roof, and down the middle of the house by a pipe into the drain; or it may be conducted direct from the gutter by a pipe, not outside the house, but inside the house, passing down through one or two stories inside the rooms, perhaps through the best bed-room in front of the house, through the drawing-room, carefully hidden by some casing made to look like an ornament, through the dining-room and kitchen into the drain in the basement. Smells having been perceived in different parts of the rooms, especially in the bed-rooms, various sanitary arrangements may be improved, and even made as perfect as they can be, by a kind of amateur tinkering prevalent nowadays in sanitary matters; and yet this defect, which is so exceedingly serious, which is known to give rise to serious disease, is entirely overlooked—perhaps for years. The same is the case when the rain-water is carried in a gutter through the roof into a gutter between the two roofs in the middle of the house, and down by a rain-water pipe inside the house. In such cases similar disasters may occur.

But there is an additional danger from the fact that these inside gutters are in themselves most pernicious things. Soot and rotten leaves collect in them, and air blows through them into the house; and especially when these gutters are under the floors of bed-rooms, this foul air is often the cause of illnesses which occur in these rooms. Even gutters which are not themselves directly connected with the drains, and which are open at both ends, but in which decayed leaves and soot accumulate and give off foul air into the rooms, may be the cause of sore throats. I have known this to be the case in rain-water gutters, which have been carried inside the house, so that they might not form an unsightly feature outside, and which have passed through the bed-rooms under the windows in a kind of position in which a sink would be. These gutters have been open at both ends, and only 10 or 12 feet long; and yet in such a case I have known illness to occur in these very rooms, which I should never have suspected to be due to these gutters if I had not known in previous cases that illness had arisen from the passage of rain-water gutters through rooms.

The housemaid's sink is often placed in a small closet just under the stairs, without any window or any sort of ventilation whatever (and we know what kind of things are kept in the sink!), so that the housemaid's sink in such a position has not by any means a very savory odor. The housemaid's sink should under no circumstances be in such a position. It should be against an outside wall and have a window. As a rule, the material used for the sink itself is lead—wood lined with lead.

The waste-pipe of the housemaid's sink, as a rule, is connected directly with the trap of the nearest water-closet. There is a grating in the sink, and there is no trap in or under the sink, but the waste-pipe is connected with the trap of the nearest water-closet. This is a bad arrangement. A worse arrangement is for the waste-pipe to be connected with the soil-pipe of the water-closet, in which case some kind of trap is generally placed on the waste-pipe of the sink. This trap is frequently what is called a "bell" trap, and is placed in the sink. The disadvantage of the bell trap is, that when you take the top of it off, you take the bell with it. The bell is the arrangement which is supposed to form the trap, by the edges of it dipping in the water in the iron box; and you see at once, when the bell is removed the trap is removed, and the waste-pipe, wherever it goes, is left wide open, and, if connected with the soil-pipe of the water-closet, the foul air comes up into the house. Very frequently, also, the waste-pipe of the sink has underneath it what is called a D trap. A D trap is a trap which the water passing through it can never clean, so it retains foul water, and, therefore, even under sinks, such traps ought not to be allowed, on account of the foul matters which accumulate in them.

The waste-pipe of the housemaid's sink should not be connected with the water-closet or soil-pipe; neither with any pipe that goes directly into the drain. Its own pipe should not go directly to the drain, which is very frequently the case, but through the wall of the house into an open head or a gully outside. Very frequently the housemaid's sink is supplied with water, not from the cistern on the roof, but from the cistern not only supplying the nearest water-closet, *but actually inside the nearest water-closet*, in which case, no matter what valves you have, you are supplying your sink with water which is kept in a cistern inside the water-closet, and that is far worse than supplying a sink with water from a cistern which also supplies the water-closet, with a reasonably protecting valve.

Close to the housemaid's sink, and very frequently over it, is the feed cistern to the hot water apparatus, which has also an overflow pipe, and the same remarks refer to this overflow pipe, except that it is a thing much more liable to be overlooked, as to the overflow pipe of the drinking-water cistern.—*Prof. Corfield, in the Sanitary Plumber.*

Lessons on Hand Railing. Price $5.00.

Stables, Fences, Out Buildings, etc. Price $2.50.

Importance of Roads.

We are not aware that any estimate has ever been made of the actual cost of the public roads of the United States, or that the expense of providing them has ever been attempted by any bureau of statistics, but we make the rough estimate that they have cost at least $700,000,000—probably much more—while unknown millions are annually expended in attempting to keep them in repair. If the money were only well applied, it would be an expenditure of great profit and economy, as everything which the farmer does off his own land is greatly affected by their condition. All his many loads of surplus farm products are drawn over them, and it makes some difference to him and to his horses whether those loads are conveyed easily over hard, smooth surfaces, or dragged through mud and against stones with severe labor to the team, fatigue to the driver, and wear and breakage to the wagon. Every week he and his family, more or less, go to the village for numberless errands, or to church on the Sabbath, and the good or bad condition of the roads seems to affect every fiber, pleasantly or unpleasantly, of their feeling or nervous sensations. On an average, there is at least twenty miles of traveling each week for the members of a single family. It would make a difference of five dollars a week, everything counted, whether this teaming and traveling is done over a nice, comfortable road, or through mud holes, sloughs, ruts, and unbridged streams, or against stones. Five dollars a week amounts to $250 a year, a snug little sum to tax the farmer with; and when this sum is multiplied by at least five million owners or drivers of horses, carriages, wagons, heavy teams, etc., the aggregate cost would be something over a billion dollars! Does any one say this is too large an estimate? Then proceed in detail and show in what particulars; but do not blindly and ignorantly say it is wrong without careful examination. Suppose, however, we admit that it is double the reality, is not the six hundred millions every year, expended directly or indirectly by our people, worthy of more attention on the part of patriots, statesmen, politicians, office seekers, public-spirited men, writers for newspapers, agricultural journalists, and in fact of every one who passes over a road?

So long as our public highways in most parts of the country are made and repaired with so little interest and so little thought, we must suffer an enormous loss. We would like to ask how many of our readers who drive or ride over the common roads, never see a loose stone, or a fixed stone, to strike, jolt, and batter every passing wheel, or who do not see hundreds of them which might be removed with the expenditure of a small portion of the road tax? How many never saw sods and muck scraped into the road bed, to form a highway or "turnpike," which would be excellent for corn and potatoes, but which when worked into a mass of mud, or cut into ruts a foot deep, constitute a strange object to be called a "road"? How many never saw along the roadsides, thrifty patches of thistles, burdocks, mulleins, John's wort, nettles, etc., etc., ready to seed all the neighbors' fields? Until we can find such happy persons in the majority, we hope more attention may be given to correcting these evils, although we would not lessen the praiseworthy attention which is now freely accorded to enterprises and interests of almost infinitely less importance, but good in their small way.

Ancient Tools.

A paper that was recently read before a scientific association in England, gives some interesting particulars about tools used by the artisans who worked on the ancient buildings of Egypt, and other moribund civilizations. The subject proved specially valuable in showing how skilled artisans performed their work 4,000 years ago. The great structures whose ruins are scattered all over North Africa and Asia Minor, demonstrate that great artisan and engineering skill must have been exercised in their construction, but when parties interested in mechanical manipulations tried to find out something about the ancient methods of doing work, they were always answered by vague platitudes about lost arts and stupendous mechanical powers which have passed into oblivion. A veil of mystery has always been found a convenient covering for a subject t at was not understood. The average literary traveler who helped to make up the tons of books that have been written about Oriental ruins, had not the penetration or the trained skill to reason from the character and marks on work what kind of a tool was employed in fashioning it.

A trained mechanic, Flanders Petrie, happened round Egypt lately, and his common sense observations and deductions have elucidated many of the mysteries that hung round the tools and methods of ancient workmen. From a careful collection of half-finished articles with the tool marks fresh upon them—and in that dry climate there seems to be no decay in a period of 4,000 years—he proves very conclusively that the hard diorite, basalt, and granite were cut with jewel-pointed tools used in the form of straight and circular saws, solid and tubular drills and graving tools, while the softer stones were picked and brought to true planes by face-plates.

That circular saws were used the proof is quite conclusive, for the recurring, cut circular marks are as distinctly seen on these imperishable stones as are the saw marks from a newly-cut pine plank. This proof of the existence of ancient circular saws is curious, for that form of saw is popularly believed to be of quite modern invention. That another device supposed to be of recent origin was in common use among Pharaoh's workmen is proved by the same authority. We have met several machinists who asserted that they made the first face-plate that ever was used in a machine shop, and we have read of several other parties who made the same claims, all within this century. Now this practical antiquary has gone to Egypt and reported that he found the ochre marks on stones made by face-plates that were used by these old-time workmen to bring the surfaces true.

As steel was not in use in these days the cutting points for tools must have been made of diamond or other hard amorphous stone set in a metallic base. The varied forms of specimens of work done show that the principal cutting tools used were long, straight saws, circular disc saws, solid drills, tubular drills, hand grainers, and lathe cutters, all of these being made on the principle of jewel points, while metallic picks, hammers, and chise s were applied where suitable. Many of the tools must have possessed intense rigidity and durability, for fragments of work were shown where the cutting was done very rapidly, one tool sinking into hard granite 1-10″ at each revolution. A curiosity in the manner of constructing tubular drills might be worthy of the attention of modern makers of mining machinery. The Egyptians not only set cutting jewels round the edge of the drill tube, as in modern crown drills, but they set them in the sides of the tube both inside and outside. By this means the hole was continually reamed larger by the tool, and the cone turned down smaller as the cutting proceeded, giving the means of withdrawing the tool more readily.

As indications on the work prove that great pressure must have been required to keep the tools cutting the deep grooves they made at every sweep, the inference is that tools which could stand the hard service they were subjected to must have been marvelously well made. Our modern tool-makers give employment to a high degree of mechanical skill, and extended metallurgical knowledge is requisite for the selection of material to make first-class tools. But when we reflect on the difficulties these ancient tool-makers had to surmount, in fastening and retaining stones as cutters on a base of bronze, we can appreciate the perfection their art reached. They probably followed methods of hardening copper alloys which are not known to us and are not discovered by modern metal workers, because the knowledge is not essential, but the real mystery of how clean cutting of hard substances was done in those times lay in the acquired skill of the tool-makers.—*American Machinist.*

Plate glass was discovered in an accidental way in 1688 by a man named Thevart. It is attributed to the breakage of a utensil containing some of the melted material, a portion of which flowed under a large flagstone, which, when subsequently removed, was found to cover a plate of glass. Thus was suggested the idea of casting glass in plates.

Grimshaw on Saws. Price $4.00.
Mechanics' Geometry. Price $5.00.
American House Carpenter. Price $5.00.
All new subscribers for 1884 will receive the balance of this year free.

The Mechanics' Fair.

For neatness of arrangement, and general good order, as shown by exhibitors generally, the Fair of 1883 compares favorably with the best that have been held. Those having goods to display are not satisfied that the old grooves should be used again, but with commendable zeal and interest have studied up new methods of interesting visitors; and the result is shown in the large number of orders given for many of the articles on exhibition. Upon entering the vast building, the fear of a conflagration is greatly modified by the display of

HARKNESS FIRE EXTINGUISHERS,

For which it is claimed that the number on exhibition is sufficient to check any fire that could possibly occur in the building. A peculiarity of the liquid used is that it will not injure the finest fabric. For this reason it is said that many ladies having expensive wardrobes have ordered these machines for private use.

ART GLASS WORKS.

A beautiful arbor, made from specimens of the artistic work of Mr. Mallon, at once arrests the attention of the observer. This is an industry that has been built up on this coast only by the exercise of an indomitable will, aided by a judgment and skill obtained only by years of study. We can commend the work of Mr. M. to those in need of anything in his line.

PACIFIC SAW WORKS.

This is, in our judgment, one of the most attractive features of the Fair. The arrangement of the hundreds of saws is truly artistic. Every kind of saw is represented, from those used by watch-makers to the mulays used by our mill-men. The energy displayed by the proprietors of these works is worthy of emulation by all of our local manufacturers, for it is to our manufactures we must ultimately look for an increase of population. We will send a fine engraving to all correspondents, representing the various saws manufactured by this Pioneer Company.

JUDSON NAIL WORKS.

This company is fortunate in having the prestige of success from the start. The superior quality of the nails made is already having the effect of diminishing the supply sent from the East. It is only a question of time when these works will be able to supply the entire Pacific Coast with all kinds of nails, spikes, etc.

IRON MANTELS—ARTISTIC TILES.

Montague & Co., as usual, are ahead of all competitors in the display of the above specialties. The mantels on exhibition are much admired for their beauty, as well as cheapness. They are made in imitation of ancient and modern marbles, and woods of all kinds, including laurel and black walnut, rosewood, etc. This firm also imports, direct from Stoke-upon-Trent, all kinds and patterns of encaustic, plain, art-painted, glazed, and majolica tiles.

BROWELL'S CHIMNEYS.

Mr. Browell is fortunate in having secured a place for the display of his chimneys where one cannot fail to see them. He presents a large variety of patent chimneys and ornamental tops. A peculiar feature of these is the easy manner in which they can be attached to a house, and the bands are so fixed that in case of the settling of the house no possible damage can be done to the chimney. Mr. B. also keeps on hand a full supply of sewer-pipe, of all sizes.

ORNAMENTAL NEWELL POSTS.

Mr. P. B. McKay makes a specialty of hardwood work, and displays a beautiful assortment of Newell posts, plain, fancy, and ornamental; also, baluster-rails, moldings, and all kinds of inside finish. Mr. McKay's long experience enables him to equal, if not surpass, any one in this same line of goods.

WEED & KINGWELL.

A beautiful display of bells, valves, lubricators, etc., is made by this firm. They have taken the lead in the manufacture of rich-toned bells, and orders are weekly received from all parts of the Pacific Slope. We understand that this firm is prepared to furnish chimes of bells for the use of churches. They also manufacture the celebrated Gordon valve, particularly adapted for outside garden hose and fire-plugs. Added to its superiority is the fact that it is much cheaper than the ordinary hose-bib.

RADIATORS AND FOLDING GATES.

Mr. Harvey has been the means of adding a new industry on this coast. His folding and extension gates are admired by all who stop to see the practical working of these safeguards against burglars. They can be fitted to a window in such a manner that in day-time they cannot be seen, and at night, when in position, they are an effectual safeguard against the opening of windows from the outside. They are also particularly applicable to store-fronts. Mr. H.'s radiators are in use all over this coast, and give general satisfaction.

HENRICKSEN'S SAFETY CLUTCH.

These clutches are now recognized as the best in use. It is impossible for the cage to fall, from the breaking of the cable, when this appliance is attached to the elevator. They are automatic in their action, and are simply the exponent of a natural law.

In our next issue we will notice several others of the more conspicuous exhibits.

Brick Mason—Separate Contracts.

The brick masons in San Francisco have perfected a society organization, mainly for the purpose of protecting themselves against losses by sub-contracting work. They neither propose nor contemplate anything in reference to prices or labor, leaving these to be regulated by demand and supply, but they request of owners and architects that all jobs of mason work—which generally includes grading and drain pipe work—which amount to more than $300, shall be let by separate contract to masons, irrespective of all other contracts. The movement is all the more worthy of consideration and favor because it emanates with the very best and most responsible of our master masons, who are actuated by no motive designed in effect to advance prices, or in any way abridge advantages to those contemplating the erection of buildings.

The principal argument used in support of the movement is the repeated failure of original contractors, and the great uncertainty of pay under the sub-contract rule. It is well known in building circles that very large amounts of money have from time to time been lost by sub-contractors through the defaults of those holding original contracts; and the present movement on the part of the master masons is to secure themselves against the uncertainties attending sub-contract work.

All new subscribers for 1884 will receive the balance of this year free.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents, in Dewey & Co.'s Scientific Press Patent Agency, 252 Market Street, S. F.]

For Week Ending September 25, 1883.

285,541.—Agricultural Boiler—S. N. Alford, Portland, Or.

285,462.—Reverberatory Furnace—J. H. Canavan, Globe, A. T.

285,463.—Plow—Jas. Clausen, San Luis Obispo, Cal.

285,465.—Lubricator—M. L. Conway, S. F.

285,740.—Fire Escape—E. C. Eyl, Jefferson City, M. T.

285,481.—Mold-board for Side-hill Plows—Paul Gregory, Davenport's Landing, Cal.

285,487.—Apparatus for Removing Sand Bars—J. H. Huffer, Jacksonville, Or.

285,753.—Nasal Inhaler and Invigorator—Jas. Keck, Portland, Or.

285,755.—Sample Exhibitor for Wall Papers—Jas. E. Kidd, Stockton, Cal.

285,757.—Slate Pencil Sharpener—W. P. Kirkland, S. F.

285,422.—Threshing and Clover-hulling Machine—A. W. Lockhart, Sacramento, Cal.

285,495.—Check Box—David Lubin, Sacramento, Cal.

285,499.—Station Indicator—Thos. Melrose, S. F.

285,508.—Amalgamating Ores and Sand Containing Gold—A. B. Paul, S. F.

285,514.—Cable Railway—Henry Root, S. F.

285,520.—Apparatus for Extinguishing Fires on Vessels—A. F. Spawn, Oakland, Cal.

285,700—Sand-guard for Railway—T. W. Stapleton, Portland, Or.

285,530.—Combined Cane and Fan—Wm. Verbeck, S. F.

285,720.—Header—Jos. H. Winn, S. F.

285,601.—Bevel Square—M. Farley, Portland, Or.

10,606.—Trade Mark—J. R. Williams, Stockton, Cal.

3,547.—Label—M. A. Scott, Livermore, Cal.

Note.—Copies of U. S. and F reign Patents furnished by Dewey & Co., in the hortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

BUILDING INTELLIGENCE.

Although our report is not as large as usual, it must not be inferred that there is a cessation of building interests. On the contrary, it is but seldom, at this season of the year, that so many buildings are seen in process of erection. One of the principal reasons for our slack report, is the absence of our regular news gatherers. During the past month they have been on a trip through the northern and southern sections of our State, and Oregon; and the good results achieved by them will be found in another part of this issue. The following list embraces all of the work in the different architects' offices, and a few others, the owners of which have dispensed with professional services:—

SAN FRANCISCO.

Contracts for Dunham & Carrigan's building, mentioned in our last report, have been awarded as follows:—
A.—Wright & Sanders.
C.—J. Hughes, brickwork; T. H. Day, carpenter.
$150,000.

Market, corner Fremont. Alterations.
O.— — Lachman.
A.—Wright & Sanders.
C.— — Haff.
$7,500.

Mission, x Sixteenth and Seventeenth. Two-story and basement frame.
O.—Dr. Wagner.
A.—Newsom Bros.
C.— — McKay.
$8,000.

Mission, x Nineteenth and Twentieth. Three-story frame.
O.—A. O. U. W.
A.—G. A. Bordwell.
C.—Gray & Stover.
$6,800.

Gough, x Fulton and McAllister. Two three-story frame.
O.—Robert Gordon.
A.—G. E. Voelkel.
C.—J. H. McKay.
$13,000.

Fulton, No. 414. Repairs.
O.—R. Gordon.
A.—G. E. Voelkel.
C.—Hutchinson & McLean
$1,060.

Jones, x Clay and Sacramento. Two-story frame.
O.—A. W. Foster.
A.—Curtis & Bennett.
C.—R. McCann.
$8,500.

Guerrero, x Twentieth and Liberty. Two two-story frame.
O.—G. E. Turner.
A.—Newsom Bros.
C.—Moore Bros.
$10,000.

Filbert, corner Buchanan. One-story frame.
O.—Mrs. J. Wright.
A.—Townsend & Wyneken
C.— — Orr.
$1,100.

Haight, near Scott. One-story frame.
O. and B.—P. Connor.
$2,200.

Point Lobos Road, near Ninth Avenue. One-story frame.
O.—G. Schmeiser.
A.—Newsom Bros.
C.—R. P. Traxler.
$2,200.

Union, nr. Hyde. Two-story frame.
O.—Mrs. White.
C.—B. F. Ellis.
$2,500.

Clipper, x Church and Sanchez. Two one-story frame.
O. and B.—R. Bergfeld.
$2,500.

Haight, x Baker and Broderick. Two-story frame.
O.—J. I. Blivins.
A.— — Pelton.
C.—W. P. Clark.
$3,500.

Hyde, corner Union. Two-story frame.
O.— — Powers.
C.— — Sinon.
$5,000.

Mission, near Twentieth. Repairs.
O.—J. C. Stubbs.
C.— — Nicoll.
$900.

California, x Gough and Octavia. Two-story and basement frame.
O.—Mr. Hyman.
A.—Schmidt & Havens.
C.—J. Furness.
$19,000.

Eddy, cor. St. Joseph Ave. Stable and alterations.
A.—McDougall & Son.
C.— — Mahon.

Geary, nr. Fillmore. Two-story frame.
O.—J. English.
A.—Daly & Pierce.
C.—W. Langstaff.
$5,500.

Geary, x Hyde and Larkin. Additions.
O.— — McKinnon.
A.—McDougall & Son.
C.—W. Langstaff.
$2,200.

Octavia, cor. Birch. Two two-story frame.
O.—Charles Christian.
A.—B. E. Henricksen.
C.—F. Klein.
$14,000.

Baker, x Clay and Sacramento. Two-story frame.
O.— — Miller.
A.—W. P. Moore.
C.— — McComish.
Days' work.

Ellis, x Fremont and Hyde. Alterations.
O.— — Strauss.
A.— — Mooser
C.— — Liernard.
$1,500.

Fulton, corner Scott. Two-story frame.
O.—Julius Newman.
A.— — Mooser.
C.— — Underwood.
$15,000.

Sutter, x Hyde and Larkin. Alterations.
O.—Mrs. M. Hicks.
A.— — Mooser.
C.— — Domas.
$1,000.

Waller, Two-story frame.
O. and B.—R. McCann.
A.— — Mitchell.
$3,000.

Pacific Ave., x Polk and Larkin. Two-story frame.
O.—George D. Bliss.
A.—T. J. Welsh.
C.—J. Blake.
$7,000.

Linden Ave., x Octavia and Laguna. One-story frame.
O.—D. J. Oliver.
A.—T. J. Welsh.
C.—P. Laherty.
$2,300.

Potrero. Two-story frame.
O.—Carroll Bros.
A.—T. J. Welsh.
C.—J. McGeary.
$4,500.

Lombard, x Taylor and Jones. Two-story frame.
O.—D. W. Tietzer.
A.— — Geilfuss.
C.—B. Dryer.
$5,000.

Lombard, x Taylor and Jones. Two-story frame.
O.—Ed. Rotger.
A.— — Geilfuss.
C.—B. Dryer.
$4,400.

Post, x Stockton and Powell. Additions.
O.—Verein Eintracht.
A.— — Geilfuss.
C.—W. Pluns.
$5,000.

WOODLAND.

One-story frame.
O.—C. Voight.
C.— — Jackson.
$1,200.

One-story frame.
O.—J. Borach.
B.—Glenn & White.
Days' work.
$800.

Improvements on hotel.
O.—L. Knight.

Two-story frame.
O.—Fred Market.
Days' work.
$1,000.

Near Town. Two-story frame.
O.—Mrs. Miller.
B.—S. Sibley.
Days' work.
$1,000.

Near Town. One-story frame.
O.—D. A. Jackson.
B.—Gilbert & Son.
Days' work.

Frame building.
O.—John Winters.
B.—Mr. W. Winne.
$2,300.

Additions.
O.—J. Roth.
Days' work.

BERKELEY.

One-story frame.
O.— — Brooks.
C.— — Embury.
$1,400.

Two-story frame.
O.— — Howells.
C.— — Lukes.
$3,500.

One-story frame.
O.— — Lingard.
C.— — Willard.
$1,000.

One and one-half-story frame
O.— — Slate.
C.— — Broad.
$2,000.

Congregational church
A.—Clinton Day.
$12,500.

Two-story frame.
O.— — Maxwell.
A.—C. Day.
C.— — Smilie.
$8,000.

MISCELLANEOUS.

Santa Rosa. Three-story brick; *O.*, County of Sonoma; *A.*, Curtis & Bennett; *C.*, Carle & Croly; $80,000.

San Rafael. Two-story frame; *O.*, Frank Zook; *A.*, Curtis & Bennett; *C.*, I. Shaver; $8,500. Two-story and attic frame; *O.*, L. Schloss; *A.*, Wright & Sanders; *C.*, J. Robertson; $25,000. Two-story frame; *O.*, Mrs. Butterworth; *A.*, W. D. Mitchell; *C.*, J. A. Jackson; $3,700.

San Jose. Julian, x Second and Third; two-story frame—B. B.; *O.*, A. Schoenheit; *A.*, Theo. Lenzen; *C.*, W. S. Boyles; $7,000. Fourth, cor. Williams; two-story frame; *O.*, Mrs. D. Murphy; *A.*, Theo. Lenzen; Days' work; $7,000.

A very modern discovery has thrown new light upon one of the most remarkable legends of the Middle Ages. Most reading people now know something about the ptomaines, the intensely poisonous alkaloids which have recently been isolated from the corrupt juices of a decomposing body, and, although the first announcement of their discovery was received with incredulity, and almost derision, are now recognized as distinct substances, existing in several varieties. Further research has shown that the new alkaloids are capable of entering into combination with other substances, yielding stable compounds having new properties, and it is found that the ordinary white arsenic easily combines with many of them, to form volatile liquids of frightfully poisonous character. The singular coincidence between this discovery and the history of the sixteenth century lies in the fact that one of the many traditions respecting the *aqua Tophana* of the Italian poisoners, that deadly drug which destroyed life instantly, and without fear of detection, relates that it was prepared by sprinkling white arsenic upon pieces of pork, and collecting the liquids which drained from them, adding subsequently a vegetable infusion. The first part of the process is exactly the same as that now found to be the easiest mode of preparing the arsenical ptomaines, and it seems altogether probable that experience may have led the refined Italian poisoners, who, as the stories go, could destroy their victims by the perfume of a bouquet, to the secret concoction of the very substances which benificent science is now adding to the list of well-known, and perhaps medicinal drugs.—*The American Architect and Building News.*

Pages preceding and following reading matter, per square, each insertion	1 50
Other inside pages, per square, each insertion	1 00
Full page, inside, one insertion	30 00
Each Subsequent insertion	25 00

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is 1 inch in length by width of the column.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

SPECIAL NOTICE TO SUBSCRIBERS.

It is our intention, in the future, to have all new subscriptions begin either with the January or July numbers. In order to have a uniform time with subscribers now on our books, credit will be given to those whose subscriptions fall due between this issue and the 1st of January, with the intervening months, so that by sending $2.00 NOW, you will receive a full receipt for 1884. All new subscribers will receive the balance of this year free.

Holding off for Lower Prices.

MANY owners are postponing the erection of contemplated improvements, having in view the idea that, owing to the advent of the winter season, the price of labor will be reduced; also, that materials of various kinds, from a cessation of building operations, will accumulate on the dealers' hands, and the latter will be only too glad to make a discount for cash.

We can assure all such, by positive information secured from lumber dealers, hardware, paint, glass, and other material men, that there is not the least chance of a fall in prices of the various materials necessary to erect and complete a building. In fact, everything tends to show that prices will be *stiff* from this onward, for some time to come.

We can positively say that lumber will not in the near future be any cheaper than it now is. During the past month it has been raised in price, and we have no doubt that as soon as the *dear public* gets used to this advance, another turn of the screw will be given, and a dollar or two be added to the already exorbitant price; and this in the face of the fact that some of the lumber dealers are complaining that their money is lying idle in the bank, and no one is willing to use it and pay a reasonable interest thereon.

The price of hardware is regulated by the Eastern market. We doubt though, even if a reduction be made in the manufacturing districts, that a corresponding price will be adopted here. The truth is that all over the State building operations were never in a more progressive state than at the present time. The demand for hardware has been such that no old stock of any kind is on the dealers' hands, and consequently there are no old patterns to work off at nominal prices and thus weaken the general market. There is not a firm of prominence in the city but takes pride in showing their customers complete new patterns in every branch of hardware.

The manufacture of paint on this coast has almost stopped shipments from the East, and as the proprietors of the manufactories are giving—in fact, always have done so—the best material at the lowest cost, no lessening of price in this commodity is to be apprehended.

The variations in the price of glass doors, windows, etc., are but very small, with the chances in favor of a raise.

Plumbing, and materials used in work in connection therewith, are as cheap now as they will be for some time to come. Under the operation of the new plumbing law, the price of plumbing has been materially advanced.

Owing to the great demand for skilled labor in every branch of mechanical work, no reduction in the price of a day's labor may be looked for. On the contrary, prices are apt to be advanced, and we have no hesitation in saying that carpenters, masons, plasterers, etc., will obtain higher wages next year than they have received during the one now about closing.

Bricks have advanced in price, and, with a strong combination holding all that can be manufactured, no decline need be looked for in this direction.

It will thus be seen that those who intend to build are more likely to have their work done cheaper at the present time than they can next year.

Another fact should be borne in mind. Each succeeding year witnesses a more general introduction of the old-fashioned moving day, and tenants prefer to move into a *new* house as long as it suits their wants. Owners consequently have none too much time in which to complete a building by the first of April.

Every architect in the State should insert his professional card in our columns, and thereby prove that he is endeavoring to assist in building up an Architectural Journal that will take rank with any now printed. The charge is but small. We want the influence your names will give, and we promise to spare no efforts in making the "California Architect" fully represent the views of a majority of the Profession on this Coast.

San Francisco Chapter, American Institute of Architects.

THE regular monthly meeting of the Chapter was held on November 2d. In the absence of the President, H. C. Macy occupied the chair.

The teachers in charge of the various classes instituted by the Chapter reported as follows:

During the month a class in mathematics was organized under the direction of J. Gash. The classes in modeling, perspective, and flat drawing were being better patronized, and the pupils showed much ambition to excel.

After discussion it was resolved that at least one member of a firm must belong to the Chapter to enable the students connected with the office to take advantage of the lessons given in the different classes.

J. E. Wolfe, of Committee on Plumbing, tendered his resignation, owing to a severe spell of sickness, which had rendered him unable to attend to the necessary duties. On motion, the resignation of the entire committee was accepted, and the President appointed the following Fellows to complete the work of

the Plumbing Committee—Messrs. Henriksen, Welsh, and Moore.

John Hall and W. Copeland were elected members as Fellows. The application of R. C. Ball was laid over till next meeting.

A communication was received from the Garland Trap Manufacturing Company, calling attention to the virtues of the traps as a sewer gas protector. A sample of the trap accompanied the communication. Placed on file.

Committee on procuring a seal for the use of the Chapter reported that they had concluded to adopt the seal used by the Association of Architects, formed some years ago.

The money premiums offered by the Chapter for the best design for seal, were to be awarded to the pupil presenting the best sketch in architectural drawing.

Trustees were authorized to procure a seal by the time of next meeting.

The following report was presented by the committee appointed to consider the proposal made by the Masons and Builders Association at the last meeting of this Chapter:—

To the San Francisco Chapter of the American Institute of Architects:—

GENTLEMEN: Your Committee appointed to consider the resolution presented to this Chapter in its October session, by the Master Masons, in reference to its segregation of all mason's work amounting to more than $300, have carefully considered the matter, and respectfully report in favor of said resolution. Respectfully submitted.

H. C. MACY,
THOS. J. WELSH,
J. GASH.

San Francisco, November 2, 1883.

The report caused considerable discussion. Objection was raised that the amount specified, $300, was too small for a separate contract. The report was finally laid on the table, with the understanding that it could be taken up at any time the Chapter may see fit.

Adjourned.

Church Building an Index to Prosperity.

ALMOST a true index to the prosperity of any State may be found in the number of its churches and schools, and we regard the establishment of the former in so many different places as a better criteron to judge by than the latter. In villages of only twenty or thirty houses, a school house is always to be found. In the majority of small communities, the school house is used as a church, exhibition room, etc. Every little entertainment is given in the village school house. When a portion of these little communities come together and resolve to build a church, or meeting-house, it is always an evidence of prosperity, for without good crops of fruit or cereals, the farmer would not be in a condition to spare a portion of his earnings for something that could be put off a little longer, and unless the village blacksmith, mechanic, and store-keepers were doing well, they could not spare money as long as the school house would do.

It is a notable fact that the founders of all the new towns south of Los Angeles—and there are dozens of them—will, in their prospectus, in large letters, proclaim the fact that the place is to be blessed with free schools and churches, the latter word generally in large type. And it seems to be a fact that the prosperity of any community depends greatly on the class that are generally found on one day of the week in their places in the country meeting-house. We do not remember of any time in the history of our State when so many small churches were in process of erection as at present. Even in some of our almost neglected mining towns, there have been enough *good folks* combine together to form a congregation, and take measures to erect a place of worship. This fact proves another thing, and that is, since the decadence of mining, the ground has been found admirably adapted to the raising of fruit, and the moment the farming element predominates, churches and schools are found a necessity.

The Master Masons' Resolution.

As heretofore announced the Master Brick Masons have banded together in an organization for mutual protection, and by resolution declared their intention to maintain the right of *original contracts* on all jobs of mason work costing more than $300. Said resolution was presented to the Chapter of Architects at its October session, and placed in the hands of a committee, who, at the meeting held on the 2d inst., reported favorably upon the petition. After a lengthy debate it was resolved to lay the subject matter on the table, etc., mainly upon the ground that by the Chapter favoring and indorsing the action of the masons, scores of other trades,—millmen, plumbers, painters, plasterers, tinsmiths, roofers, sewer-layers, graders, etc., etc.,—might, with equal propriety, set up similar claims and an indorsement of the Chapter, thus involving the Chapter in an almost endless series of contract issues.

The adoption of the resolution and the organization of the Masons' Society presupposes a reason for such action. This is found in the simple fact that sub-contractors in all the various branches of building operations have, during the past thirty years, been subjected to repeated and sometimes ruinous losses through the irresponsibility and defaults of original contractors. In a very large number of such cases the defaults have amounted to downright business salaries, while others have been the result of incompetent men undertaking work far below prices sufficient to enable the payment of actual costs. It is not therefore to be wondered at that the masons have made the move they have, and we trust that they will so thoroughly organize and co-operate as one man, that neither designing rogues nor men incapable of estimating true values of things to be done, will be able to cheat and defraud better men of their rights.

In behalf of the few worthy and responsible contractors (carpenters), it is scarcely necessary to say a word. They stand above reproach; and if buildings were never let to others than our first-class men there would have been no necessity for any masons' organization. The brick masons nor any other branch care an iota who they work for so long as payments are sure. But in view of the fact that uncertainty of pay in full surrounds a very large proportion of the building contracts let in San Francisco, there should be no surprise felt that sub-contractors should seek protection.

The Pacific States Historian.

HUBERT H. BANCROFT was born at Granville, Ohio, in 1832. His parents were from New England. At the age of sixteen Mr. Bancroft entered the bookstore, in Buffalo, of his brother-in-law, George H. Derby, who, in 1852, sent him to California with a stock of books and stationery. Mr. Derby died before the goods reached San Francisco; but true to the original purpose, Mr. Bancroft, in 1856, opened in a modest way the establishment which in less than thirty years was one of the largest of the kind in the world. Shortly after beginning business he began collecting material for a history of the Pacific States, by which term is signified the western half of North America, from Alaska to Panama, including all of Central America and Mexico. After gathering all that America would yield he several times visited Europe, always with marked success, until his collection numbered 35,000 volumes. Then he erected a brick building specially for his library on Valencia Street, San Francisco.

But long before this he began to write. He studied hard and wrote diligently. As preliminary to his historical series, in 1875 he published the "Native Races of the Pacific States," in five volumes, which was received with universal commendation throughout the world. The most eminent scholars of Europe and America were lavish in their praise of it. Then came the "History of the Pacific States," which is indeed a series of histories, altogether covering the entire coast, one twelfth of the earth's surface, and probably the greatest work of the kind ever undertaken by mortal man.

In all there are to be thirty-nine volumes. Volume XI. has just been printed. They are all uniform in size and binding. Any information in regard to the above can be had by addressing the office of this Journal.

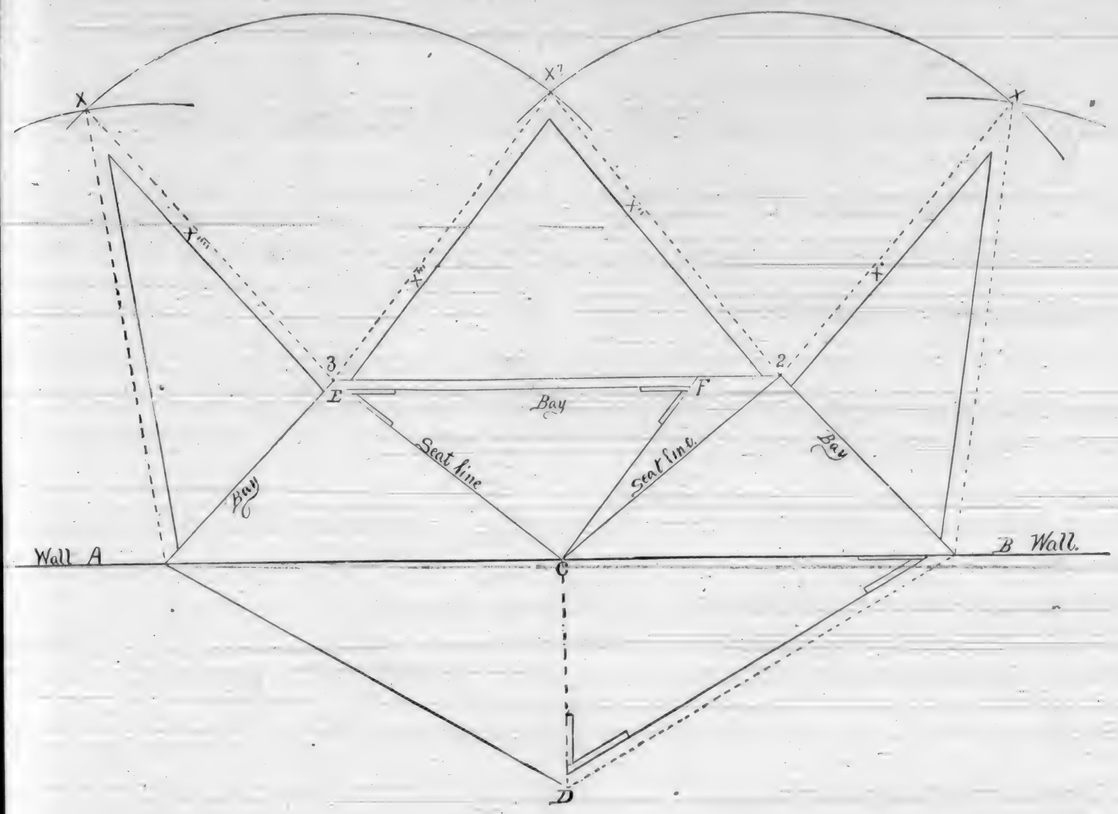
BUILDING SUPERINTENDENCE.

A Manual for Young Architects, Students, and others interested in Building Operations as carried on at the present day.

WE received a copy of the above work from the Publishers, J. R. Osgood & Co., too late for extended notice in this issue. From a hasty perusal, we conclude that young architects, as well as those persons not of the profession who are occasionally called upon to direct building operations, will be greatly benefited by a careful study of this work. Its author is T. M. Clark, well known to many of our readers.

We will send a copy of the above work to any address upon receipt of the price, $4.00.

"Vodge's Architect and Builder's Pocket Companion and Price Book Edition of 1883," revised and enlarged, $2.00.



A GRAPHIC DESCRIPTION, ILLUSTRATING THE METHOD OF STANDING THE CUTS OF THE HIPS OF BAY WINDOWS OVER GROUND PLAN IN POSITION. (SEE ABOVE DIAGRAM.)

A B is the wall line; A 3 2 B is the ground plan; C D is the elevation; C B, C 2, and C 3 are seat lines; square from C 3 seat line makes C F equal elevation; then F E is the length and cut that will correctly stand over seat line C E. Draw a line D to B, then take the distance D B in the compass, stand on the angle B, draw a curve as $\times$; now don't change distance you hold in your compass, but stand in angle A, draw another curve $\times$; now set the compass to the distance already found, namely, E F, and stand with compass on angle 2, draw a curve cutting right and left, as $\times$ $\times^7$; stand on angle 3 with same distance as from angle 2, and draw curve cutting $\times$ $\times^7$; draw lines as shown, A $\times$, $\times^{III}$ 3, 3 $\times^7$, $\times^7$ 2, 2 $\times$, $\times$ B; now commence to cut along the dotted lines as shown, and hinge from B to 2, and from 2 to 3, and from 3 to A, and from C to B; fold up and they will stand over ground plan in position. M. J. MARION.

We have dotted the lines as shown, to illustrate the value of models. Take a sharp knife and cut the paper along the dotted lines; fold up the parts separated and the practical working of the above problem will be at once apparent. We would advise our readers, however, to make the diagram on a piece of card board, following the explanation closely, thus saving the above for future reference.

Mr. M. J. Marion, the author of the above neat study, has decided to remain for awhile in this city. He has in his possession testimonials from some of the most celebrated architects, mechanical engineers, and surveyors in the United States His system of teaching lines is strictly original with himself. For the present he can be found at 631 Sacramento Street. Draughtsmen, students, builders, etc., would do well to engage his services.

Building.

WE have received a copy of the illustrated edition of *Building*. It contains nineteen selections from foreign architectural journals. The purpose of this edition is to give selections from leading papers of Europe. The editor naively remarks, "We have ordered every journal of value published in England or on the Continent." The best of the ideas culled from these will be given in *Building*. Terms, $5.00 per year. Orders received at this office.

Plaster and Plastering—How to Make and How to Use It.

A new work, and by far the best yet brought to our notice. It is a complete guide for the plasterer in the preparation and application of all kinds of plaster, stucco cement, lime, etc., with useful and practical information on the chemistry, qualities and uses of the various kinds of limes and cements, together with rules for measuring, computing and valuing plaster and stucco work.

Price, Postpaid, $1.00.

HYATT'S PATENT ILLUMINATING ROOF AND ROOF BASEMENT.

Three different kinds of Artificial Stone Illuminating Tiles, as well as that of Iron made by the Undersigned, under the Hyatt Patent, with Jackson's Patented Improvements.

Owners of property using any of these improvements, as well as the makers thereof, unless manufactured by the undersigned, will become liable for damages for infringements.

P. H. JACKSON,
Attorney for Mrs. E. A. Hyatt.

P. H. JACKSON & CO.,
No. 2 California Street and 231 First St., S. F.

Architecture of Country Houses.

BY A. CURTIS BOND.

In this letter I have shown a double country house with plans, and for the information of our architect friends, or those who would like to put the design into actual use, I propose to give the specifications. The building, as will be seen, is frame, and combines two dwellings under one roof, and has recently been put up in the suburbs of the city at a cost of $1,600.

The architect, Mr. A. F. W. Leslie, thus writes:—

The main house is 27 feet deep, and 48 feet front, with an extension 13x30 feet. Cellar 7 feet high. First story 9 feet 2 inches; all the measurements to be between timbers.

All frame timbers to be of first quality, and all as well seasoned as can be had. All timbers for joiners' work to be free from loose or black knots, and well seasoned.

SIZE AND KIND OF TIMBER.

Sills 2x8, posts 4x8, plates 2x6, first and second story joists 2x10. All joists supporting partition to be 3x4. Rafters 2x5.

EXTERIOR

To be first covered with hemlock or spruce, well nailed, laid over diagonally, then with sheath paper, then with first-quality pine beveled clap-boards not over six inches wide, and to lap not less than ¾ of an inch. Corner-board 1¼x4 inches, and 1⅛ inch, ¼ round in angle, well nailed. Water-table 1¼x6 inches, and beveled on top with lip. Window and door casing outside to be 1¼x4 inches, and according to scale drawing shown herewith. (See illustration.)

ROOFS.

First covered with good hemlock boards, then with sheathing-paper, and then with good blue slates, with chipped corner ridges to be covered with tin and well flashed around chimneys in good, workmanlike manner; valley to be well lined in workmanlike manner with charcoal tin. Gutters to be framed as per scale drawings, and lined with best charcoal tin and well soldered. Roof of piazza and bay window to be finished as main roof.

PIAZZA.

Build piazza as shown on plan. Rear platform at kitchen door to be supported by 5x5 inch chestnut posts, extending high enough to support a plain hand-rail finished with cross supports, made box-shaped, with beveled edges. Steps 1¼ inches, well-secured stringers 1¼ inches, risers ⅞ of an inch, all finished in a neat manner.

CASINGS.

All inside door and window casings to be ⅞x6 inches, with cove and berth; base to be 6 inches high. All to be finished with a neat moulding of any pattern.

DOORS.

All doors, except outside and sliding-doors, to be 1¼ inch thick, moulded on both sides, except closet doors, which shall be moulded on room side only. Front and sliding-doors to be 1⅜ inch thick, with raised mouldings. Front door to be hung with 4x4 inch bronze bolt. Sliding-door to be fitted with track and rollers. Suitable locks on all doors, with porcelain knobs, except front door, which must have bronze knob.

WINDOWS AND BLINDS.

All windows to be glazed with second-quality French glass, except cellar window, which must be American make. All windows to be hung by cord and weight, and good sash fastenings. Rolling slat blinds on all windows, with good trimmings. Cellar window to be hung with button and good hook.

STAIRS

To be as shown on plan, with a 7-inch Newel, 4-inch moulded rail, 1¼-inch baluster, all of walnut, neatly and strongly fitted up. Box stairs leading to cellar.

FENCE.

Build fence around entire lot as may be selected.

MANTELS.

Make neat wooden mantels in kitchen, dining-room, and chamber, to cost not less than $10.00 each. One slate or marble mantel in each parlor, to cost not less than $20.00 each, all set.

PLUMBING.

Iron sink, porcelain-lined, 18x30 inches, to be fitted up in kitchen where shown on plan, ceiled up and small door underneath; fitted with tin waste-pipe to connect with drain. Sink fitted with a pump with suction-pipe leading to the bottom of the cistern.

PAINTING.

All work usually painted should have two good coats of best white lead and oil, and of such color as may be selected.

MASONRY.

Masons to excavate for cellar, privy, and cistern, and earth deposition to grade. Foundation to be laid up of stone to within 6 inches of grade, balance 8 inches built wall, a good 10-inch footing cover to start with below cellar bottom. Chimney as shown on plan, carried up to roof with common brick, and topped out with good quality face brick, all to be well plastered from top to bottom.

PLASTERING.

All to be lathed with good spruce laths, then plastered with two good coats, well troweled, to make a good job. Parlor and dining-room and front hall to be hard-finished, and a neat cornice and center-piece in each parlor.

Build cistern and privy sink where directed, in a good, workmanlike manner.

All necessary culture and all carpenter work described, to be done in a neat manner, and all defects rectified and left completed.

The materials all are to be of the best of their several kinds, and all work herein specified, to be done in the best and most workmanlike manner, and finished throughout.

* * * * * * * * *

The common use here of shingles in house-building has led to other means of coloring than that of paint. Staining the exterior is often adopted, although the stain is, in itself, less durable than paint, for out of door work, although the action of the weather washes out the color in some degree, and has the effect of softening the tints and blending them harmoniously together. These softened and blended effects have a charm in the diversity of shades, while painting has a monotonous appearance. A more weathered look is given to the shingle work, which much enhances the picturesque effect. The best mode of applying the stain is by using turpentine or oil as a medium. The mixture of color and oil, says a writer, should be thinned with considerable turpentine, so that it will strike in the wood. The surface afterwards should receive two coats of oil. Or, the stain may be applied with turpentine, or by adding the oil in separate coats, to preserve the color. Vinegar is sometimes used as a vehicle, and with success. The aftercoats of oil are indispensable to a permanent application, and two coats of oil on the top of the stain should be used. Other modes of staining may be used. The natural color of the shingles is sometimes sufficient, and in this case they are often simply dipped into oil before fixing, or a little color may be added to the oil. The California redwood is a warm and agreeable material, needing only oiling to bring out the color or heighten the tone. Varnish is sometimes applied to the oiled shingles, but the gloss is objectionable, and the coloring is spoiled. The manner of laying the shingles has a great deal to do with the effect of the treatment, as the same stain may give different appearances according as they are laid in straight courses or otherwise. They are often laid so as to break up the surfaces as much as possible, in which case the tone of color will appear darker by the half shadows. Perhaps the most pleasing broken and varied effects are obtained by using ordinary rough-sawn shingles, which gives a shadowed surface, and the stain is unequally taken up by the wood. The colors employed for shingle work are numerous. The shingled or upper stories of a house may be stained a yellowish or orange color, and the dressings, or trimmings, as they are called, a dull shade of bluish green. The lower story may be of a dark reddish tone. In other instances the stain may be of light tints of Indian red or yellow, red and black, burnt sienna with burnt umber, old gold, obtained by using Indian yellow and blue black, brown madder and burnt sienna. More or less contrast can be had by using cool colors in the trimmings, such as blue gray, and warm colors on the surfaces; such as burnt umber, Indian red, sienna. Harmonies are obtained by making one color enter with all the others, or by making the trimmings agree with the body colors, although of lighter tone. In other cases the artist may choose a graded treatment, using different shades of the same color, contrasting with a complementary color. Thus, the body of the house may be in three shades of green, the deepest being placed on the ground story, and the lighter shades in the second and upper stories. A dulled red may be used for the trim-

(*Concluded from Page 180.*)

mings. Shingle roofs are often painted a deep red of dull tone, but the coloring soon gets dark from weathering. Venetian red, burnt umber, and lamp-black make a good mixture for this purpose. One author observes, the darkened or dulled scales of color are to be preferred to pure tints. The last require to be produced by white, and are apt to be weak and sickly in expression. Somber coloring gives a character and dignity which light tints fail to produce. The powerful contrasts of complementary colors are generally less pleasing than a harmony of coloring, that is, where the normal colors are darkened or dulled by mixing with black or gray. According to such a treatment, the preservation of the same character is observed throughout the composition, and the hues and tones have a relation with each other. In other words, the most pleasing coloring for external purposes is that where the contrast produced is that of tone. Such a harmony never wearies, like that produced by crude complementary colors.

* * * * * * * *

It may interest my readers to learn of some protection to iron, in building, from rust. It seems that some French engineer observed that several chains embedded in mortar for a number of years were in no way affected by rust. It was in a bridge that he noticed this peculiarity; so he investigated and found that iron does not rust in water in which are dissolved small quantities of caustic alkalies, or alkaline earths, which neutralize every possible trace of acid. Following up this fact, paint has been made containing caustic alkaline earth. Although a thin coat of paint cannot contain so much alkali as a thick bed of mortar, the alkaline action will still have an effect so long as the coating has a certain consistence. Under any circumstances these new paints will be free from active acids. They are called Riegelman's paints, and have not yet, I believe, been brought to this country.

REMARKS ON THE ABOVE.

We have given the article just as received from our correspondent. Many of the materials specified would not be applicable to this section of the country. The cost mentioned is far below the price for which the building could be erected in this city. With specifications made in keeping with materials and work necessary to complete plan as usually called for in buildings of this kind, the cost would not be less than $3,700, and probably $4,000 would be nearer the true figure.

CHICAGO is the greatest lumber market in the world. The single item of sawed lumber received there in 1881 would lay an inch flooring fourteen feet wide round the earth at the equator. The amount of lumber manufactured in the three States of Michigan, Wisconsin, and Minnesota during 1881 would lay such a floor fifty feet wide.

All new subscribers for 1884 will receive the balance of this year free.

American House Carpenter. Price $5.00.

Chats With Clients.

"THE fact is, I want a house that is totally different from any other house that was ever built."

"Totally different?"

"Yes, absolutely unlike anything that ever was seen on the face of the earth."

"You are an extraordinary man, and have an extraordinary family, I suppose?"

"Well, no, I can't exactly say that, but I'm sick of this everlasting sameness, and I want something that will sort of make people open their eyes and wonder what kind of a fellow it is that lives in such a house. I tell you there's nothing like a little originality in the world."

"You want the house to suit your peculiar needs and circumstances?"

"That's it precisely. I want it to fit me just like a hat or a pair of boots. If I want a suit of clothes made I don't send another man to be measured, I go myself. Same thing with a house. If it don't fit me I can't live in it with any comfort. Now, you know I'm not exactly like anybody else; I'm not even a twin. Consequently my house ought to be—it ought to be—"

"*Totally* unlike anything else ever seen on the face of the earth."

"Perhaps that's putting it a little strong, but you know what I mean, at least you ought to. If you can't give me anything new, why then I don't see the need of having any plans."

"What do you say to a house of one room?"

"One room! That wouldn't answer at all. We must have about the usual number of rooms, of course."

"And of about the 'usual' size?"

"Yes."

"Not much chance for originality there."

"Can't you arrange them in some novel way?"

"Possibly. How would it suit you to set them all in a row, or around in a circle, or one above another—tower of Babel fashion—that would be novel in a dwelling-house."

"Altogether too much so. But I wasn't thinking so much about the inside; that of necessity must be similar to other house-keeping establishments."

"Oh, I understand, you wish to *appear* to be original; that's easier still. Build a high basement of white birch logs with the bark on, the first story of anthracite coal laid in red mortar, second of railroad ties painted blue, and shingle the roof with tin pans, use empty flour barrels for chimneys, get the top of an old 'one-horse shay' for a front porch, and hang all the window curtains on the outside."

"Oh, fie! you're making fun of me. I want something sensible and practical, but not exactly like the common run of cheap houses."

"Why didn't you say so! Originality, like the true poet, is born, not made; unless it springs from an honest expression of your needs and circumstances, and a simple endeavor to meet them in a downright rational fashion, it will be a sham. Arrange the rooms as you want them, taking into account the location and outside surroundings as well as the internal needs, but without any special anxiety concerning the exterior. Build the walls of the first story of good, honest, natural stones, which abound on your farm. Cover the second story, which will be of wood, with cypress shingles, oiled, but not painted, and the roof with red tiles. If the total result lacks novelty, you can console yourself with the reflection that commonplace obscurity is preferable to conspicuous deformity.

"The materials that I have mentioned are all easily obtained; they are unobjectionable in point of economy and durability; they are especially suitable for the rough and rugged location where the house will stand, and will surely look well unless you force the structure to make false pretenses for the sake of challenging the stupid wonder of your neighbors."

—*The Builder.*

Great Pyramid Hieroglyphics.

EDITORS ARCHITECT: In your September issue, the question is asked why the Great Pyramid should be entirely barren of hieroglyphics, in a country where every object of interest seems to be covered with them. From a careful study of the works of travelers and historians who have made this grand monument the subject for their most careful consideration, I find that originally it was beautifully cased and covered with hieroglyphics. According to the Hindoo records, it was "cased with colored marbles," which at least is probable, as fragments of marble and granite were found among the debris.

Herodotus states: "On the outside were inscribed in Egyptian characters the various sums of money expended in the progress of the work." In Wilkinson's Hand Book of Egypt we find that "it was covered with a smooth, inaccessible casing." Dean Stanley adds: "It also seems that these smooth outsides were covered with sculpture."

Dr. Shaw says: "It was incrusted all over with the finest granite marble."

The above opinions are confirmed by Abd-el-Lateef, who states that "the polished exterior stones were covered with writing, which, if copied upon paper, would fill more than ten thousand pages."

As a settlement of the dispute upon this subject, Col. Howard Vyse, in 1837 actually discovered two of the casing-stones *in situ:* and on the Pyramid of Chephren, near by, more than ten thousand square feet of the original casing may still be seen.

It is a historical fact that the casing-stones of the Great Pyramid were removed in A. D. 1166, by order of Sultan Saladin, to build his citadel at Cairo. Yours truly, G. F.

Should this Journal be received by any Subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

☞ Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas send us a sketch of them and we will make the cuts.

EDITOR ARCHITECT: Will you please give me information through the columns of your journal upon the following queries: What are the wages of carpenters in San Francisco? How long do jobs last? What chance would a stranger have in your city of getting steady employment? How long does your rainy season last, and its effect upon the time of mechanics? By answering the above you will greatly oblige not only myself, but several others, who desire to locate in San Francisco.

Yours respectfully, C. V. TOTHILL.
Chicago.

Wages depend altogether upon the skill and activity of the man. A stranger would perhaps have to be satisfied at first with $3.00 per day. This rate could be raised in a short time by carefully observing the *style* in which work is done, and noticing the different finishes used in various houses, and the manner in which they are *put on*. Even a first-class mechanic from the East would find it necessary to devote time and study to the business, as done in this city, in order to obtain the full rate of wages. Three to four dollars per day is the ruling price, foremen getting from 50 cents to $1.00 per day advance on these figures.

A stranger, if he be able, intelligent, and competent, would find but little trouble in securing work.

The length of a job depends somewhat upon the man with whom you get employment. Some contractors keep a gang of men in steady work nearly through the entire year. It takes from three to six months to erect and finish a building of average cost, say from $5,000 to $20,000.

Eastern mechanics have an erroneous idea in regard to our rainy season. It generally commences with a few showers in September. October passes, with a few rainy days. During the present season, up to the 1st of November, about 2 inches of rain have fallen. November may be said to be our Indian Summer, some of our most pleasant weather occurring between the 1st of Nov. and Christmas. From the latter part of December to April, it is wet, off and on, same as any other place, but very seldom more than three days at a time being rainy. Snow is seldom seen in San Francisco, and our winter season is about the same as in any other place of the same latitude where snow is not found at this time of the year. If you are lucky enough to get on a job that is just housed in before the rainy season gets fully started, the chances are that you will lose no more time than you would in any other State under similar conditions. There is almost a complete absence of snow, and with the thermometer seldom below 30° above zero, we think there are but few places which offer superior advantages to *first-class* workmen.

Items of Interest to Draughtsmen.

WARM water is better than cold for rubbing up Indian Ink.

WHEN it becomes necessary to trim a piece of rubber, it will be found that the knife will cut much more readily if dipped in water.

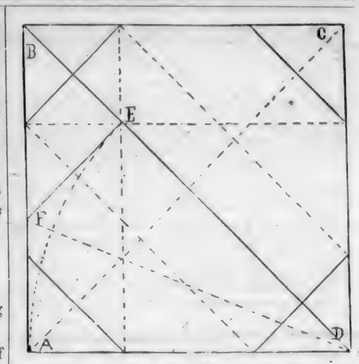
WHEN paste is used to fasten papers to a board, both sides of the paper should be dampened, as the paste takes longer to dry.

IN sharpening pencils, be sure the knife-blade has a good edge. Many a pencil has been half cut away on account of the blade being dull, on account of the undue pressure necessary.

STALE bread makes an excellent means of cleaning up a drawing. It will hardly remove pencil lines of any strength, but it clears up the surface beautifully. Avoid the crust, as it may dent and scratch the paper when rubbed upon it.

IN selecting a pen, care should be taken to see that the nibs are of the same length, and that they are of sufficient thickness. In some pens the metal is so thin that the nibs really cut into the paper, and another disadvantage is, that in using the very moderate amount of pressure necessary to keep the back nib against the ruler, the two surfaces of the metal become nearly in contact, and the line becomes uneven. A fine pen will not necessarily make fine lines; a pen of medium size, if in order, will work as finely, and the larger handle is more convenient to hold.

IT has been a mystery to some people why the dark wood so highly prized for furniture should be called "rosewood." Its color certainly does not look much like a rose, so we must look for some other reason. An exchange explains that when the tree is first cut, the fresh wood possesses a very strong, rose-like fragrance; hence the name. There are a half dozen or more kinds of rosewood trees. The varieties are also found in South America and in the East Indies and neighboring islands. Sometimes the trees grow so large that planks four feet broad and ten feet in length can be cut from them. These broad planks are principally used to make the tops of piano-fortes. When growing in the forest, the tree is remarkable for its beauty, but such is its value in manufacturing as an ornamental wood that some of the forests where it once grew abundantly now have scarcely a single specimen.



NEWARK, N. J., October 13, 1883.

EDITOR CALIFORNIA ARCHITECT AND BUILDING NEWS:—Fig. 1 exhibits the operation of finding the sides of an eight-sided polygon, and also the angle to mitre the sides.

To find the sides of an eight-sided polygon, draw the square A B C and D equilateral and equiangular; join D B. From the point D as a center, with D A as a radius, describe an arc, cutting D B in E. Then E B equals the side of the polygon, and E F D equals the angle to mitre the sides.

By the use of the square to mitre the sides, place the square with E D on the blade, and E B on the tongue; mark from the latter for the angle required.

By calculation—Let E D equal 18x18 inches, equal 324 plus 324 inches, equal 648 inches, square root of which is 25.4558 inches, minus 18 inches, equals 7.4558 inches, or 7 and 7-16ths inches equal E B.

By proportion—7.4558 inches : : 18 inches : 7.5 inches; 7.5 x 18 inches equal 135 inches; divided by 7.4558 inches equal 18.1067 inches, or 18 and 3-32d inches equal E D.

I am yours, L. D. GOULD.

Wheeler's Patent Wood Filler.

A NOTABLE progress has been made in the appearance of the different finishes used in a building, since the introduction of this celebrated preparation. By its use the pores of the wood are filled so that a beautiful smooth surface is obtained which could not be had without its use. Although it seems to have been originally designed more especially for hardwoods, it has been found by actual test to be adapted to the softer redwoods and fir, so generally used on this coast. For curly redwood it has no equal, as it brings out the *grain* of the wood better than any other article of its kind. It is also being extensively used by our piano and furniture manufacturers. It can be obtained from all the principal dealers in paints, etc., on the coast.

In-Doors and Out.

A NEW publication, devoted to sanitary and rural improvement, has made its appearance on our desk. Its items on Healthy Homes and Beautiful Surroundings are decidedly unique in their originality. The price has been fixed at 50 cents per year. The office is at 119 Pearl Street, New York.

Popular Fallacies in Regard to Ventilation.

By Dr. Chas. R. Dryer, of the Fort Wayne College of Medicine.

The first and great popular fallacy in regard to ventilation is that it needs no special attention. This is a more serious error among the well-to-do than among the poorer classes, inasmuch as the houses of the former are more nearly air-tight. With solid brick walls, double-sashed windows, weather-stripped doors, and a base-burning coal stove, the exclusion of pure air is carried to the utmost extent. This condition is happily somewhat relieved by the use of open coal grates. But how many fine houses does the physician enter without noticing the close, foul odor, and the stifling air which comes from over-heating and poor ventilation? In such rooms he finds nervous, headachy women, and pale, irritable children, suffering from colds the winter through. Such families need judicious instruction that respired air contains one of the most virulent poisons known, and that dry and overheated air is debilitating and irritating, leaving the mucous membrane sensitive, to be inflamed by every breath of the natural atmosphere.

The second popular fallacy is that the poison of respired air is carbonic acid.

This is an example of superstition at the "survival" in science of an idea long after it has been proved to be false. It is perpetuated in school text-books and popular treatises innumerable. Indeed, correctness of statement upon the subject is this rare exception; gross error the rule.

Carbonic acid gas is no more poisonous than water; animals immersed in it die just as they do if immersed in water, and for the same reason, viz., want of oxygen. Birds have been made to live in an atmosphere containing 35-40 per cent. of pure carbonic acid, and about an equal per cent. of oxygen. Yet when the carbonic acid of *respired air* rises to one per cent. that air is very dangerous poison. The solution of this puzzle is that respired air contains a very small proportion of poisonous organic matter, which is constantly exhaled from even the healthiest lungs. Its exact nature has not been determined. It is the source of the foul odor so characteristic of badly ventilated rooms. The air from the exit of pipes of a crowded hall darkens sulphuric acid, decolorizes potassium permanganate, and causes water, or a sponge saturated with it, to putrefy. This poisonous matter is produced in quantities proportionate to the amount of carbonic acid, hence the quantity of the latter is an indicator of the relative quantity of the power, and carbonic acid should never be allowed to accumulate in occupied rooms to the extent of seven-tenths of one per cent.

The third popular fallacy is that the most impure air accumulates near the floor of the room. This false idea has probably arisen from the fact that carbonic acid is more than half as heavy again as air, and can be poured from one dish to another like water. Although this is true when both gases are at the same temperature, a very little difference of temperature is sufficient to reverse these conditions. Respired air issues from the nostrils at a temperature of nearly 100° Fahrenheit, and is lighter than the outer air at 70° or 80°. Again, the temperature of the body is nearly 100°, usually much above that of the surrounding air. This is sufficient to create an upward current rising from the body of every person in the room, just as the heated air rises above a hot stove. If to these influences be added the more powerful action of a stove, register, or other heating apparatus, it will be understood how the impure air rises and accumulates very rapidly near the ceiling. This can easily be proved by experiment, such as placing candles at various heights. The upper one will burn much more dimly than the lower. At the same time the cooler air from the floor moves toward the stove to enter it, or to join the current rising from it.

The fourth popular fallacy is that the outlet for impure air is best placed at the top of the room, and the inlet for pure air at the bottom.

This may seem a contradiction to the third fallacy, but is not, for several reasons. An opening into a cold place at the top of the room is often not an outlet at all, but simply allows cold air to drop down into the room. If it be an outlet it is very wasteful of heat. The air of the room is heated at some expense, and then turned out of doors as soon as possible. If the inlet be near the floor, there will be a cold draught upon the feet of the occupants of the room, and although such an arrangement may ventilate, it will be attended with such disadvantages as to render it highly objectionable. Wherever possible, there should be an outlet near the floor into a heated flue, in which the upward draught is sufficient to constantly draw the cooler air off the floor. An open fire flue is the most efficient outlet that can be devised. Instead of that, a direct draught stove in which a door above the fire may be opened, answers the purpose admirably. The inlet may be for pure heated air through a register near the floor on the opposite side of the room from the outlet, or for pure cold air by an opening directed upward behind the stove, and above the heads of the occupants of the room. Thus all cold draughts will be avoided; the pure cold air will mingle immediately with the impure air near the ceiling, and the room will be equably and economically warmed and efficiently ventilated. June air may be had in January, and the children will be as merry and rosy as the street children, who have nothing but oxygen to make them merry.

THERE are churches and mosques in Palestine on the roofs of which you could stand from two to five thousand people.

All new subscribers for 1884 will receive the balance of this year free.

How to Cleanse the Waste Pipes.

ONE of the most frequent and trying annoyances of housekeeping, as many can testify, and which a writer in the Philadelphia *Ledger* freely asserts, is the obstruction to the free, quick outlet of the waste water of the wash-stand, the bath-tub, and the kitchen sink.

This is caused by a gradual accumulation of small bits of refuse material, paper, rags, meat, bones, or other offal, which check and finally entirely stop the outflow of the waste water, and then the plumber is called to remove the stoppage with his force pump.

Sometimes this is effective; at others the offending waste pipe is cut out and a new one put in its place at considerable cost.

But the plumber is not always near at hand or free to come at one's call, and the matter demands immediate attention. A simple, inexpensive method of clearing the pipe is as follows: Just before retiring at night pour into the pipe enough *liquid* potash lye of 36° strength to fill the "trap," as it is called, or ben' portion of the pipe just below the outlet. About a pint will suffice for a wash-stand, or a quart for a bath-tub or kitchen sink. *Be sure that no water runs into it till next morning.*

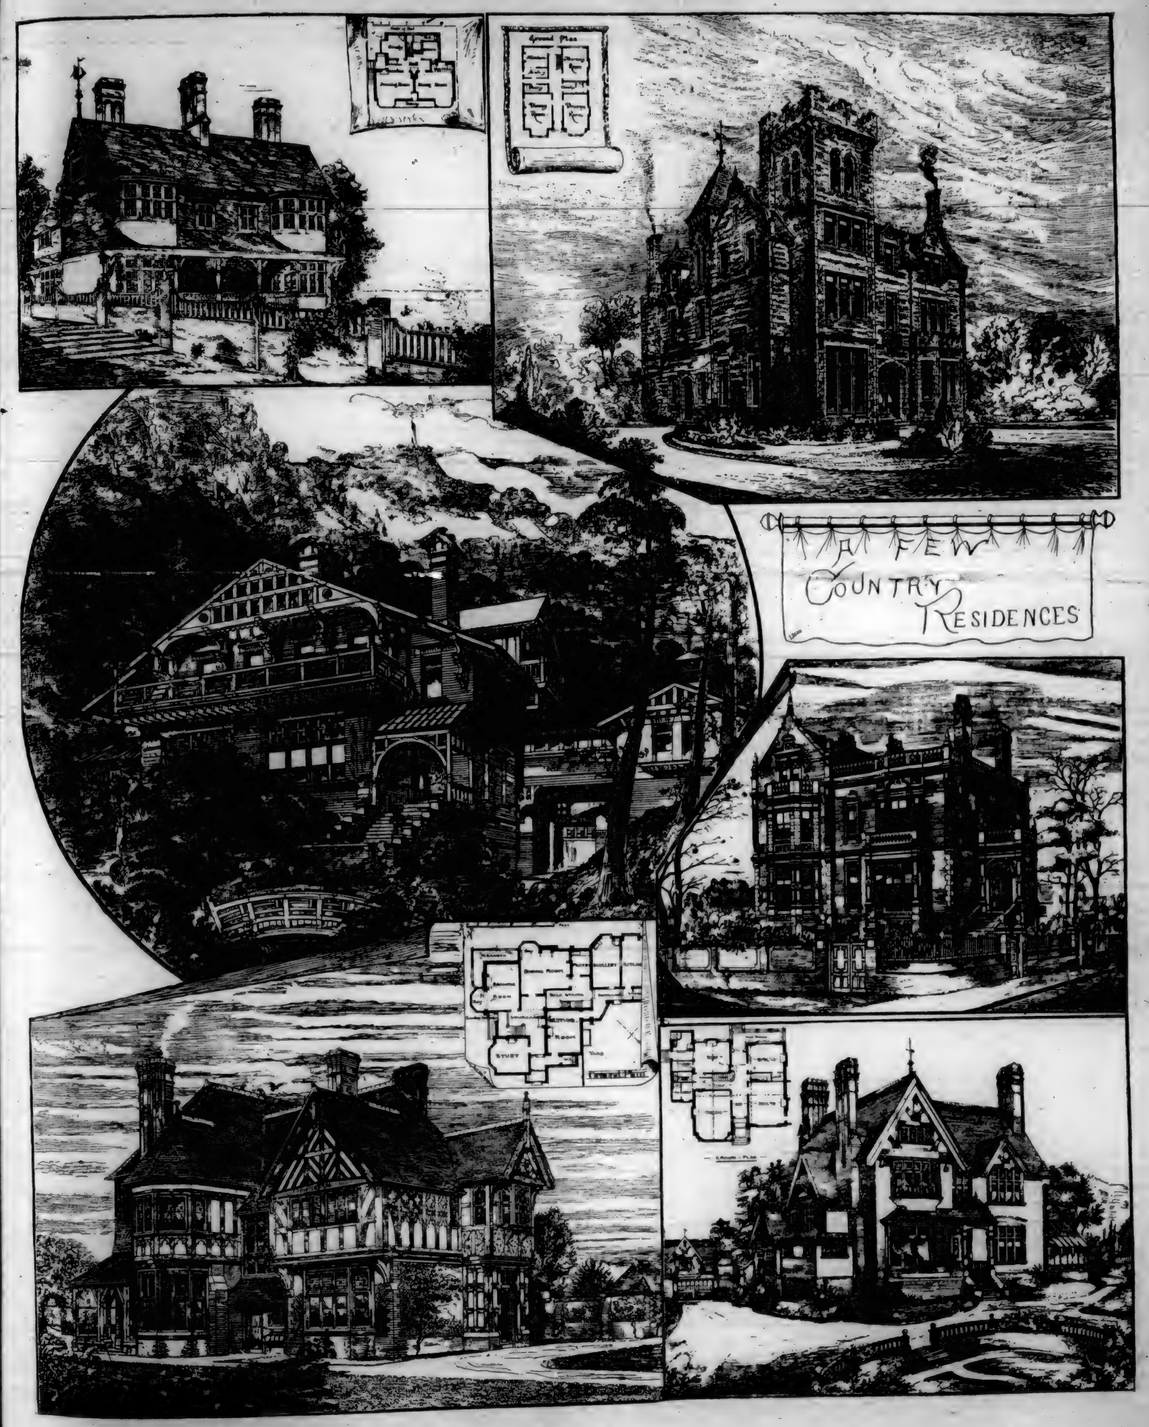
During the night the lye will convert all of the offal in the pipe into *soft soap*, and the first current of water in the morning will remove it entirely, and leave the pipe as clean as new. The writer has never had occasion, in over thirty years' experience, to make more than two applications of it in any one case.

A remarkable example of the value of this process was that of a large drain pipe which carried off the waste of an extensive country house, near Philadelphia, and ran under a beautiful lawn in its front. A gallon of the lye removed all obstruction in a single night, and saved the necessity of digging up the pipe and disfiguring the greensward of the lawn, as the plumber intended until advised of this process.

The so-called potash lye sold in small tin cans in the shops is not recommended for this purpose; it is quite commonly misnamed, and is called caustic *soda*, which makes a *hard* soap. The lye should be kept in heavy glass bottles or demijohns, covered with wicker work, and plainly labeled; always under lock when not in actual use. It does not act upon metals, and so does not corrode the pipes as do strong acids.

IN the whole world there are no known redwood forests outside of California. It is a significant fact, however, that one-fourth more finished lumber, suitable for interior housework, can be obtained from Humboldt timber than from timber grown in any other county in that State. Unlike many other kinds of trees, redwood stumps can be utilized to profitable advantage. For veneering purposes, slices from these stumps are said to be highly prized, and may probably in time prove almost invaluable.—*American Lumberman.*

American House Carpenter. Price $5.00.



New Zealand Insurance Company.

THE property upon which this building is to be erected was purchased last month from Sir Robert Burnett, of Aberdeen, Scotland, Newhall heirs, and Moses Rosenbaum, of this city, at a cost of $158,000. The frontage of the three properties thus concentrated measures 60 feet on California Street, viz., Nos. 310, 312, and 314, with depth of 124 feet and rear frontage to Halleck Street of 62 feet and 11 inches. As will be seen hereafter, this rear approach is a great advantage, when the purposes for which the building has been designed are explained. The whole area is to be covered by a massive six-story building of pressed and enameled brick, Oamaru, New Zealand free stone, and California granite. The elevations on California Street and Halleck Street are so arranged as to allow of a very large area of plateglass for the purpose of making the interior as light and comfortable as possible. This is the more easily obtainable from the fact that the property is on the sunny side of California Street. Light areas have been left in the plan of each story to brighten the rear portion of the offices on both fronts. The arrangement of offices on the ground floor is something novel for this city. On each side of a twelve-foot corridor there is a handsome office 22x60 feet, with vaults, complete for bank or insurance purposes. About the center of the building, dividing the front from the rear offices, is a space of, say 25 feet. This is utilized for stairway and double elevator on the right, and closets and sinks on the left. The elevators will be a novelty in architecture in this city, being constructed on the same principle as those in the Union Bank Building, New York. They will be on the compensating principle, as one goes up the other descends, thus obviating the frequent delay occasioned by having to wait on an upper story, with the mortification of knowing that the machine has to descend to the very basement, and then go to the top of the building again before you can reach the street. This corridor leads to the main office of the New Zealand Insurance Company, with floor area of 32x56 feet. The ceiling of this spacious room will be 34 feet in height, handsomely groined and arched. It will be lit by cathedral windows occupying the whole frontage of 62 11-12ths feet on Halleck Street, and so arranged as to give the greatest possible accommodation. The detail of this room will be finished in natural woods, and so designed as to make it, perhaps, the most perfect and beautiful insurance office in the United States. Within this room will be located the offices of the New Zealand Insurance Company, the agencies of the New Zealand Loan and Mercantile Agency Company, the New Zealand Stud and Pedigree Company, and the Correspondent of the Bank of New Zealand. It is not often that such a combination of foreign institutions is to be found together in one counting-house. The New Zealand Insurance Company sets an example that we hope will be shortly followed by other institutions of a similar character in anchoring itself in this substantial way to our city, thereby removing all excuse for a continuance of the otherwise reasonable complaint of the drain of local premiums by foreign Insurance Companies. The Manager of the New Zealand Insurance Company has furnished us with the following synopsis of its history:—

It was established in Auckland, New Zealand, in May, 1859, by a few leading men, with paid-up capital of $24,225. In 1862 its paid-up capital had increased to $75,000; in July, 1863, to $150,000; in July, 1864, to $225,000; in January, 1865, to $250,000; in 1871, to $375,000; in 1873, to $500,000, and to-day the paid-up capital stands at $1,000,000, and assets over $2,000,000, *with unlimited liability of share-holders.* When foreign capital represented by companies of this calibre comes to our shores, and identifies itself with our citizens, as the New Zealand Insurance Company has done, we cannot do better than take it into the family, and the more the companies invest with us the better we will like it. Had the investment been made by a company hailing from London, there would not be so much to be astonished about, because we can give them a much greater return than can be obtained in the United Kingdom, but it has remained for the progressive and youngest of Britain's daughters to come in by the Golden Gate, and put New Zealand money, which brings a higher rate of interest at home, into property in San Francisco. We hope this enterprising company will reap the reward it deserves in initiating this new departure, and that increased business and profit may accrue thereby. The design of this fine structure was furnished by Messrs. Wright & Sanders.

The following statement of the condition and affairs of the New Zealand Insurance Company of Auckland, in the British Colony, New Zealand, on the 30th day of November, A. D. 1882, and for the year ending on that day, was made to the Insurance Commissioner of the State of California, pursuant to the provisions of Sections 610 and 611 of the Political Code, condensed as per blank furnished by the Insurance Commissioner:—

CAPITAL	$5,000,000 00
Amount of capital stock paid up in cash	$1,000,000 00

UNLIMITED LIABILITY OF SHAREHOLDERS.

ASSETS.

Real Estate owned by Company	$480,216 00
Loans on bond and mortgage	820,704 00
Cash market value of all stocks and bonds owned by Company	639,700 00
Amount of loans secured by pledge of bonds, stocks, and other marketable securities as collateral	58,055 00
Cash in Company's office	2,068 00
Cash in Banks	25,108 00
Interest due and accrued on all stocks and loans	20,497 00
Premiums in due course of collection	7,105 00
Bills receivable, not matured, taken for fire and marine risks	10,537 00
Due by branches and agencies	34,368 00
Rents due and accrued	425 00
Total Assets	$2,098,768 00

LIABILITIES.

Losses in process of adjustment or in suspense, and appropriations for property tax	$112,645 00
Gross premiums on fire risks running one year or less, $455,006 00; re-insurance fifty per cent	227,503 00
Gross premiums on marine and inland navigation risk, $135,845 00; re-insurance one hundred per cent	135,845 00
Gross premiums on marine time risks, re-insurance fifty per cent	33,920 00
Sundry accounts owing	235 00
Deposits	11,000 00
Joint stock capital actually paid up	1,000,000 00
Surplus beyond capital and all other liabilities	577,620 00
Total Liabilities	$2,098,768 00

INCOME.

Net cash actually received for fire premiums	455,006 00
Net cash actually received for marine premiums	530,964 00
Received for interest and dividends on bonds, stocks, loans, and from all other sources	127,970 00
Total Income	$1,113,940 00

EXPENDITURES.

Net amount paid for fire losses (including appropriations for unpaid losses)	$ 274,940 00
Net amount paid for marine losses (including appropriations for unpaid losses	388,245 00
Dividends to stockholders	150,000 00
Paid for salaries, fees, and other charges for officers, clerks, etc	209,520 00
Paid for State, national, and local taxes	5,405 00
Fire and marine associations, insurance brigades, and S. corps	8,900 00
Total Expenditures	$1,037,010 00

LOSSES.

	Fire.	Marine.
Incurred during the year	$274,940 00	$388,245 00

RISKS AND PREMIUMS.

	Fire Risks.	Premiums.
Net amt. in force November 30, 1882	$60,750,785	$439,851 00
Risks written in State of California	5,110,854	63,362 00
	Marine Risks.	Premiums.
Net amt. in force November 30, 1882	$14,456,730	$180,709 00

Improved Rapid Method of Copying Drawings, Manuscripts, Etc.

THE common method of copying drawings by contact with the blue process or sensitive silver paper, which requires an exposure to the sun of from fifteen minutes to half an hour, seems likely to be superseded to some extent by the introduction of improved gelatine bromide of silver paper.

Gelatine sensitive paper has been difficult to prepare, but by means of recent improvements the manufacturers are now able to furnish it in large sheets uniformly coated, so that its use in various branches of the arts promises to be extensive.

Architects, draughtsmen, engineers, and others who wish to make duplicate copies of their drawings are, by the usual processes, obliged to first make a tracing upon transparent linen cloth, so that the light may easily affect the sensitive paper. Much extra time is lost and expense incurred. By means of the gelatine sensitive paper any ordinary thick card-board drawing can be copied in a few seconds, either by diffused daylight or gas or lamp-light. The copy will be an exact reproduction of the original, showing the letters or figures non reversed.

If it is desired to make a copy in the daytime, any dark closet will answer, where all white light is excluded. The tools required are an ordinary photograph printing frame and a red lantern or lamp.

The sensitive gelatine paper is cut to the size required, and laid with the sensitive side upward upon the face of the drawing, and pressed thereon in the usual manner, by springs at the back of the frame, which is then carried to the window and exposed with the glass side outward from two to five seconds to the light, the exposure varying according to the thickness of the drawing. If gas or lamp-light is used at night, from twenty to thirty minutes exposure is sufficient.

The frame is returned to the dark closet; the exposed sheet is removed to a dark box, and other duplicates of the drawing can be made in the same way. It is thus possible to make from ten to twenty copies of one thick drawing in the same time that it usually takes to obtain one copy of a transparent tracing by the ordinary blue process.

The treatment of the exposed sheets is quite simple; all that is necessary is to provide from three to four large pans or a large sink divided into partitions. The development of the exposed sheets can be carried on at night or at any convenient time, but a red light only must be used. The paper is first passed through a dish or pan of water and then immersed in a solution, face upward, composed of eight parts of a saturated solution of oxalate of potash to one part of a saturated solution of sulphate of iron, enough to cover the face of the paper. Both chemicals are easily obtained at a druggist's. The latent image soon appears, and a beautiful copy of the drawing is obtained, black where the original was white, with clear white lines to represent the white lines of the drawing. With one solution from six to eight copies can be developed, one right after the other. After development the print is dipped in a dish of clear water for a minute, and finally immersed for three minutes in the final or fixing solution, composed of one part of hyposulphite of soda dissolved in six parts of water. It is then removed to a last dish of water, face downward, soaked for a few minutes, then hung up to dry; when dry it is ready for use. Instead of a drawing, manuscript can be placed in the printing frame and exposed as described. All the water marks or peculiarities of the grain of the paper will be faithfully reproduced. The advantages of this process are self-evident.

Intricate mechanical drawings can be so rapidly copied that working copies can be quickly delivered. By this process original manuscripts, certificates, and documents of every kind can be rapidly copied, every detail being brought out, the original paper serving as the negative, the copy being of the exact size as the original.—*Scientific American.*

Handsaws.

SEVERANCE of material was doubtless among the first difficulties which confronted mankind, and to meet this the primal saw, as being at once simple and effective, whether it was the jaw-bone of a snake, the back-bone of a fish, a jagged flint, or whatever else it may have been, was adopted, and furnished the idea for future development far in the long night before the dawn of history. The Greek story is that Talus found the jaw-bone of a snake, and, after discovering from it the properties of a saw, imitated it by notching a piece of metal, and was killed by his uncle through jealousy. Other myths run that Perdix used the back-bone of a fish as a saw, was changed into a partridge by the envious gods, and deified by his countrymen. But the Greeks were egregious wondermongers and liars, and the saw was in use before that people came into the eyes of the world. It was a common tool among the ancient Egyptians, and many specimens of their saws are yet preserved. Even among that people it had lost much of its primitive rudeness, and was made of bronze with teeth well ground or cut out, and was inserted in a handle like the modern case-knife, or bound to the same with thongs and operated with one hand. The teeth were pointed from the handle, and the cutting was done by a thrust movement, as in modern saws. The material to be sawed was placed upright and lashed to posts set in the ground. The Egyptians, as also the Phœnicians, used saws for cutting stone as well as wood, and the stones in the temple of Solomon were faced with saws. Samuel, 1033 B. C., mentions them casually. A two-handed saw has been found in the ruins of Nimroud, and many saws have been brought to light in Thebes.

In the stone age, saws were made of flakes of flint set into a back of wood, and secured by means of bitumen, and the early dwellers in Europe also notched shells. As late as 1768, Captain Cook found the South Sea Islanders using saws made of sharks' teeth lashed to a back piece by sinews. Saws made of obsidian were used in ancient Mexico, and specimens of these have been found buried under the deposits of sand and gravel in New Jersey, proving the existence of a prehistoric coast trade along the Atlantic, obsidian not being found nearer New Jersey than Mexico.

Saws of the bronze age have been discovered in considerable numbers, both in Germany and Denmark, but none have yet been found in England. These are made of plates cast very thin and then cut out.

Modern Oriental saws all have the teeth pointed toward the handle, and are operated by a drag movement. This manner of sawing and pointing the teeth seems to be most suitable to rapid sawing, but does not admit of as great accuracy as the thrust movement.

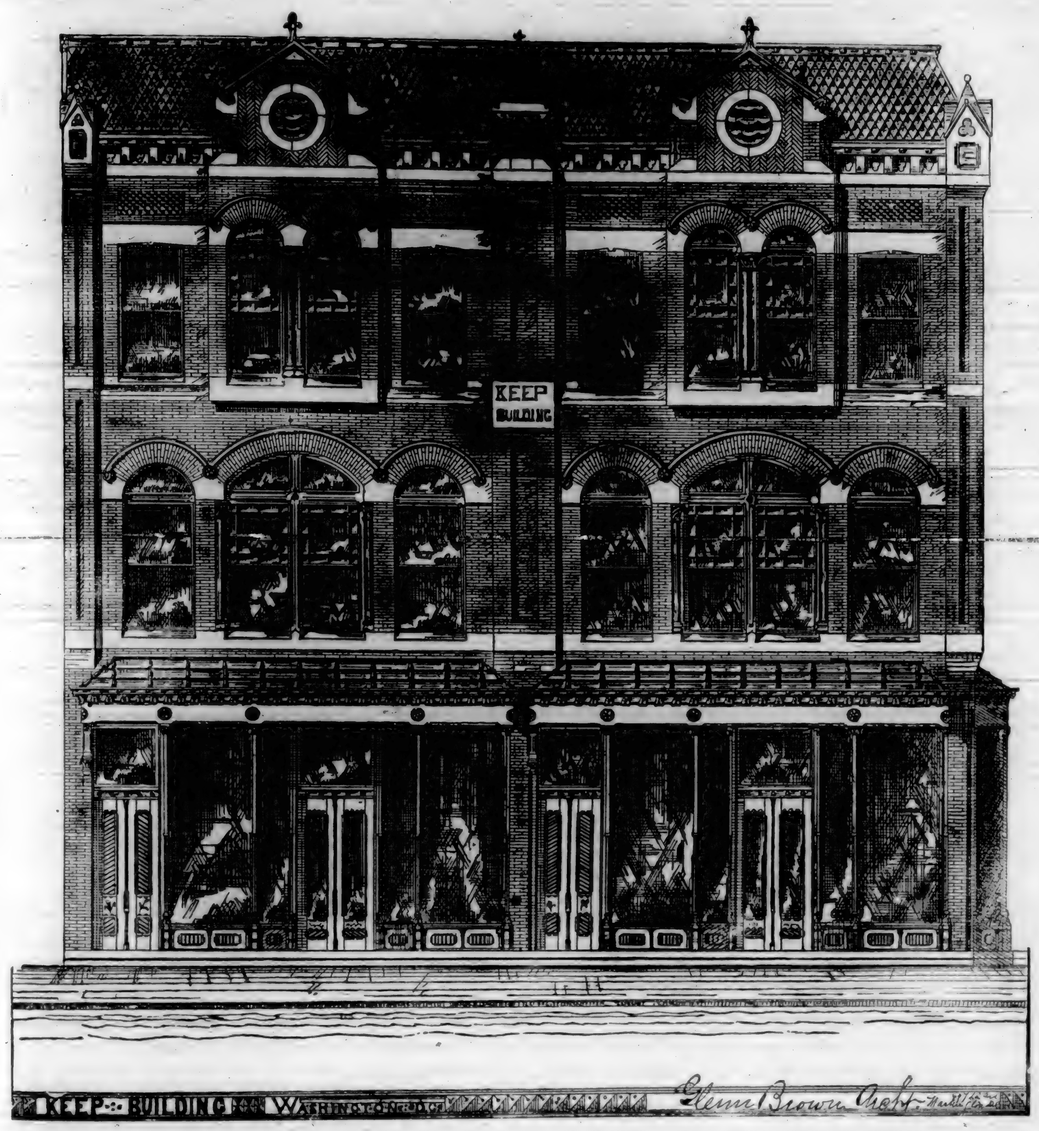
The Japanese saw is shaped like a butcher's cleaver, and has a flat handle which looks as if it might have been whittled out of an inch board, to which it is attached by wrapping tightly with fine split cane. The teeth are very narrow and long, and the sawyer stands on the plank to be sawed, and works with short, rapid, upward strokes.

The plates from which saws are made are rolled from ingots of steel carefully and uniformly tempered and varying in thickness according to the kind of saw to be made. After the blanks for the saws are stamped out, they are further tempered to the desired point by heating, and then immersed in oil for about five minutes. This oil is partially removed by sawdust, and the temper is then let down by reheating and slow cooling. The blank is then straightened by hammering, and the edge, upon which the teeth are to be cut, trimmed, after which the teeth are punched by a fly-press and then filed, tempered, oiled, and wiped, and heated till the oil blazes off. It is then hammered, ground, and glazed and grained with emery, the teeth set, and the blade properly stiffened by heating. Any discoloration is then removed by an acid, and the saw oiled. The correct spacing of the teeth is effected by means of either a double chisel or a file guide. Saws are made tapering from the tooth side to the back in order that they may not pinch or clog in the groove or kerf.

The French method is to roll the blade several times cold in order to make the grain close and the metal homogeneous. It is then heated in a furnace especially designed for the purpose, from which the air is excluded, and then bathed in colza oil in a dark chamber, and tempered by means of a machine in which the blade passes through cast-iron plates heated to a fixed temperature.—*Call Smith, in Industrial World.*

GASES from the furnaces in iron districts are very injurious to trees in the neighborhood. The sulphuric acid contained in the gases is absorbed by the leaves.

Mechanics' Geometry. Price $5.00.



DESIGN OF STORE FRONT, BY GLENN BROWN, ARCHITECT.

The Directors of the University of Southern California, at Los Angeles, California, desire to receive from Architects competition plans, with elevation, for the erection of a brick University Building, at a cost not exceeding $60,000. For particulars address undersigned Committee,

Los Angeles, California.

E. F. SPENCE,
R. M. WEDNEY,
A. M. HOUGH.

BUILDER AND WOOD WORKER.

We continue this year our friendly relations with this most excellent publication, and will send to any address one year's numbers of the "Builder and Wood Worker," in connection with the "California Architect and Building News," for $2.50. The influence of such journals as the above has had a marked tendency to elevate the thoughts of mechanics, so that now we find them exercising more head work in the performance of their labor. This is especially noticeable in country mechanics. We often receive letters inquiring for the best Eastern journal that gives the various new styles at present in vogue. We can unhesitatingly recommend the above.

Special and Sub-Contracts in Building Construction.

THE following remarks from the *Builder* will aptly apply to the professionals of this country:—

"However, as regards one point of recent correspondence—as to an architect's right to scrutinize sub-contracts made between a general and a subordinate contractor for any part of the work connected with a contract—much, of course, depends upon the circumstances and the standing of the contractor employed. Most architects claim the right to closely scrutinize everything done in connection with the erection and completion of the buildings they have designed, of whose requirements they are the best judges, and most experienced contractors do not appear to deny this. The commonly accepted version of a contractor's duties under his contract is that the work will be carried out by competent workmen, under the eyes of proper foremen, at daily wages, in his (the general contractor's) direct employ; and so far at least as London custom is concerned, we know that this is the ordinary practice of all leading contractors. Should an architect find any evasion of the conditions, or should he find that a sub-contract had been made with some subordinate contractor for any of the structural portions of the work, entirely foreign to him—in fact, objectionable, and not what he had a right to expect—it would be difficult to say that he had not a clear right to interfere and insist upon the conditions of the contract being fulfilled, which commonly would be covered by the clause that 'no part of the work shall be sub-let,' &c. Of course, when a contractor has the confidence of an experienced architect, he (the architect) would not have the least desire, nor, in fact, would he find it to his client's advantage to harass the contractor about matters of minor detail connected with his (the contractor's) methods of arranging his business in his own way, and especially when there should be no need for such interference; at the same time, it would look like taking a one-sided view of an architect's proper position—standing, as he does, between the contractor and the client, to see strict justice done to both—to say that he has no concern with sub-contracts entered into between a general and subordinate contractor, because there might occur circumstances when he would have much to do with such arrangements.

"Then as to whether the frequent insertion, in architect's specifications, of the names of special firms of merchants, manufacturers, and others from whom materials connected with the structural work must be obtained—such as the stone, bricks, slates, &c.,—is a modern and unnecessary innovation whenever it occurs, and a sign of undue partiality for certain firms not superior to others, when there exists a large field, so to speak, of firms quite as good, and fully capable of supplying the same class and quality of goods, whether the selection of the most suitable is not more properly a matter for the judgment of the contractor, who undertakes all the risks, and is held to be solely responsible, are questions upon which opinion is not altogether one way. The object, of course, is to obtain the fittest and the best, and certainly the old school of architects seemed to have no difficulty in meeting the case without any special predilections. The careful wording of their specifications was with them, as is now with such of them as remain, of far greater importance to the solidity of their buildings, and their general effect, when finished, than any sentimental preference for the goods of any particular firm of merchants or manufacturers. Of course, these remarks apply to the ordinary run of specifications. Before passing on, it may be mentioned that an authority has said, 'Ambiguity is the bane of modern specifications.' Touching again the question of special or separate contracts made between architect and specialists, or others, and the bearing upon the general contractor and clerk of works, it is necessary that both of them should be fully acquainted with all the details connected with such contracts—that is, as regards what is actually included; whether the builder's work and attendances, &c., have been provided for and included in the estimates, or the contrary. This necessary information on all points should not be given simply orally, as is too frequently the case, not even when directed by the tip of a fluent tongue, but should be fixed in writing. Many specialists give little if any specification describing clearly and in full detail, for the information of others, what they have included in their contracts, and not unfrequently are they their own interpreters of what they have or have not included, and especially does this occur in connection with what is called the 'builder's work'; the general contractor, knowing nothing, hesitates, or acts upon the word of the clerk of works, who may know as little, but, nevertheless, has to arrange and look forward. Any settled arrangement tending to the avoidance of cross charges, misunderstandings, confusion of accounts—and this is really what it comes to—should be welcome to all interests concerned. Here, as in the general work, we may not inaptly quote again, 'Ambiguity is the bane of modern specifications.'"

Five Per Cent. Gain vs. Ten Per Cent. Loss.

IT has been remarked by an able correspondent, writing upon the subject of sub-contracts, that, "It is a difficult matter to bring proof as to the amount of profit derivable from any branch of the building trade." To my mind, this is true, and it rather amusingly reminds one of the tortures described by the experienced in connection with the mystic word "prime-cost;" it is capable of an elastic interpretation according to circumstances, and many astute brains have been before now puzzled over it, and it has not unfrequently been found to contain within itself a considerable element of profit. It need not be said that the "prime cost," as understood by all leading architects and contractors, is that which represents the *net* cost of the labor and materials, &c., without any further additions whatever; it is then susceptible of taking its legitimate and fair profit.

A.

Much soreness has occurred before now by what may be called an anomalous practice, stated to be not so rare as it should be, viz., contractors of standing and repute being invited to tender for works in competition with others not of equal standing, and doing what may be termed a cheap class of work. The former, as is the custom, do not know the names of other competitors; in result, one of the latter usually gets the contract, and the former would not have wasted time and money in working up tenders, but they would have declined had they known beforehand with whom they were classed in competition. The public should understand that it is not with building affairs as with many of the other concerns of life; the apparent saving of 5 per cent. in a contract may, as it has in very many instances before now, prove a 10 per cent. loss.

B.

A Result of Co-operation.

WORKINGMEN managing a co-operative establishment, and performing their own labor, would undoubtedly experience seasons when they would be compelled to accept not only smaller dividends but lower wages, in order to have any dividends at all. Still it is well known that men when working for themselves will put up with privations, and hardships even, which they would not think of submitting to if imposed upon them by others. One of the indirect advantages of co-operative production will be the cultivation of economy, saving, and thrift, among the workingmen who engage in it. The interest in such an establishment would form a nucleus to which every honorable and ambitious workman would have a just pride in adding something every month.—*Western Manufacturer.*

A Curious Discovery.

ONE by one the scenes of the old Franciscan Fathers are being brought to light as excavations are made near the old mission. A singular discovery was made near the city of San Luis Obispo a few days since. The *Tribune* is authority for the statement that some workmen, in making excavations on the side of the San Luis Obispo Mountain, discovered an ancient smelting furnace, the remains of the arches and smelting pots, or crucibles, being quite abundant. The discovery, when taken in connection with the tradition that the old missions of the coast had an abundance of crude silver, is quite significant. The remains of such a furnace are known to exist in the mountains back of Santa Barbara and Ventura, and piles of slag attest the amount of work done there in former times.

Stables, Fences, Out Buildings, etc. Price $2.50.

All new subscribers for 1884 will receive the balance of this year free.

THE BENEFITS OF TREES.

Their Effect on Climate, Soil, and Mankind.

AN interesting paper on "Forestry" was read before the Geographical Society lately by C. A. Washburne. He began by speaking of the increase of the population of the world. Mr. Washburne took the opposite stand-point from Malthus, and said that we should not try to devise plans of preventing the increase of population, but to devise means to provide food for them. The world could be made to support seven times its present population, and that way is by increasing our forests. By planting our now barren hills with trees, it would leave them plenty of land in the valley to cultivate grain. It is an undeniable fact that where trees are in abundance the country is thrifty. Speaking of the devastation of timber lands, the speaker cited Arabia, Syria, Egypt, and the countries of the Old World. At one period in the world's history these places supported a vast population, beautiful cities, and wealthy kingdoms. Now there are no more barren places on the face of the earth than are the places that were once the pride of the world. The cause of this wonderful change, according to Mr. Washburne's ideas, was the destruction of the timber. History tells us that many of these countries were once fertile and productive, but as the population increased the forests were destroyed, and the cessation of rains has made them what they are now. California is coming to the same end in the course of time, if we do not profit by the experience of the ancients and save our forests, or, at least, not allow them to become annihilated. Taking the scientific stand-point of the effect of forests in their influence on the rain-fall, the speaker contended that as forests are removed so will the fall of rain decrease, and to substantiate his theory and the theory of scientific men, he cited the effect of cutting off the timber among the Appennines, and in Lombardy. Germany and England, on the other hand, are still thriving nations, and one great cause is that care is taken to preserve the fertility of the soil and keep up their forests. Old Spain again is the reverse. The country is desolate and its people thriftless on account of the lack of vegetation. The effect of planting trees in our own country, especially in California, is very noticeable. Many of our valleys and grain lands are very open, over which the winds sweep, drying up the soil and blighting the crops. In those places where the prudent farmer has planted long rows of trees, the violence of the wind is broken and the growing crops are saved. Where trees grow, rain, on which we all depend, will fall. The only exceptions to the rule of forests and rain going together are the pampas of South America and our great Western plains; but these exceptions, as explained by scientists, are due to the fact that the rain-bearing winds that blow over them are condensed by the trade winds. The farmers in Nebraska, Iowa, and Illinois, are fast exhausting the fertility of the soil, and if they continue to do so in less than two centuries these places will be as barren as the plains around Damascus are at the present day. The speaker then compared the difference in beauty and valuation of two farms, one on which no trees were planted, and another where trees grew in abundance.

The Price of Lumber.

A NEW combination has been formed among the lumber dealers, by which the *dear public are assured* that, in the near future, no danger need be apprehended that any discounts will be allowed below the schedule prices. It has been the custom heretofore to allow contractors 10 per cent. on the rates established by the Lumber Manufacturers' Association; but the managers of that institution have wisely (?) allowed that it would be best for the interests of owners to have them understand precisely the cost of lumber used in the construction of their houses and thus be sure that a portion of the extravagant prices (?) asked by contractors should find its way in the capacious pockets of the poor men who supply lumber.

And, in order that they can thus guard the interests of owners, each one of the poor men forming the association has deposited the sum of $10,000, which shall become forfeited in case lumber is sold for a less price than their law prescribes.

The *dear public* have been so faithfully served by the members forming the association that it is expected that they will readily acquiesce in the demands of the lumber dealers, and not allow the rich contractors to hoard as much wealth as they have done in the past.

Seriously, though, we will be pleased when the time comes that lumber will remain at a fair regular price for a year at a time, so that those who are calculating to commence extensive improvements in the future may be able to judge somewhere near the cost of building before commencing operations.

Every Architect Should Become Identified With the Chapter.

DURING the past month we have had several calls from draughtsmen, seeking information in regard to the classes established by the Chapter of Architects. Three of the applicants were connected with architectural firms in this city.

We would call the attention of architects not identified with the Chapter that it is for their interest to join at once; especially now, as it is the beginning of the year. The small outlay required will be more than gained by the knowledge the students and draughtsmen under your charge will gain under the leadership of the gentlemen who so generously give their time for the advancement of the younger members of the profession. The dues are but small—$6.00 per year.

The Chapter is one of the most flourishing in the United States, numbering forty-six members; it also has a goodly amount of cash in the treasury. Hand in your names at once for membership. Office of the Secretary may be found at room 11, 240 Montgomery Street.

THE *Manufacturer and Builder* gives a simple process for preparing the luminous paint now coming slowly into use. The ingredients of the mixture are simply sulphur and lime, the latter being obtained from oyster shells, which are to be washed with warm water, and calcined for half an hour, then allowed to cool, pulverized, and the white portions separated from the gray refuse. The white lime is then to be put in a crucible, in alternate layers with flour of sulphur, and the cover luted on with a mixture of clay and sand, moistened with beer. The crucible is exposed to a bright flame for an hour, and is then, after cooling, broken open, when the contents will be found of a mottled white and gray color. The gray portions are to be separated and thrown away, but the white part is to be finely ground and sifted through muslin, after which it may be mixed with varnish, oil, or size, and used like ordinary paint. It is essential that objects painted with this substance, which are intended to be luminous at night, should be exposed to sunshine or bright light during the day. If so treated, the paint will retain its qualities indefinitely.

A CAVITY in a grindstone may be repaired as follows: Take a piece of old grindstone, and pound it up quite fine, or procure some fine, sharp sand and sift out the coarsest, using only the fine; make this into a paste with one-third the bulk of hydraulic lime or cement and sufficient water-glass; undercut the cavity in the grindstone, or drill key-holes in it, and fill it with the cement as above made. It will harden very rapidly. Very good artificial stones may be made in this manner in a mould, to which considerable pressure can be applied.

A MACHINE for plastering walls has been invented. It consists of a receptacle for the mortar, the segments of a cylinder in form. It is provided with a hinged leaf or press plate that moves rapidly against the mortar, and as the receptacle is moved upward against the wall, the plaster presses out through a narrow-gauged opening at the bottom.

All new subscribers for 1884 will receive the balance of this year free.

THE CALIFORNIA ARCHITECT would like to know when dealers will be satisfied with a *fair profit* on lumber, and thus enable those of limited means to erect buildings, and keep within their means for so doing.

DENSE forests are increasing in Australia the climate is growing more moist, and even the great central desert may become habitable.

School House and Church Architecture. Price $4.00.

THIRTY per cent. of forest is considered the best proportion for the most beneficial effect on climate.

Detail Cottage and Constructive Architecture. Price $10.00.

AN active tool never grows rusty.

History of Glass.

In the year A. D. 676, "messengers were sent out," according to Bede, from Wearmouth, England, to Gaul, France, to fetch makers of glass (artificers), "who were at this time unknown in England, that they might glaze the windows of the church, with the cloisters and dining-rooms." Bede adds that "they taught the English nation their handicraft, which was well adapted for inclosing the lanterns of the church, and for the vessels required for various uses." About this time Archbishop Wilfred, of York, "filled with glass" the windows of the cathedral, previously "open to the weather," and "such glass," says one, "as permitted the sun to shine through;" from which it may be inferred that glass was made that was impenetrable to the sun's rays. It was recorded, in connection with this cathedral, that "great astonishment was excited, and superstitious agency suspected, when the moon and stars were seen through a material which excluded the inclemency of the weather." Still, the adoption of glass was slow; for in 1214 Robert de Lindeley, Abbot of Peterborough, employed glass "in beautifying thirty of the windows of his monastery, previously stuffed with straw, to keep out the wind and rain;" and for some generations later the domestic windows of England were not furnished with glass, but lattice. When glass windows were first introduced, they were not fixtures, but were regarded as movable chattels, and were so considered until about A. D. 1600.—*Sel.*

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of United States Patents in DEWEY & Co's SCIENTIFIC PRESS PATENT AGENCY, 252 Market Street, San Francisco.

FOR WEEK ENDING OCTOBER 23, 1883.

286,993.—FLOWER-POT HOLDER AND SHIELD—Wm. A. Birch, San Francisco.

287,094.—STATION INDICATOR—W. W. Campbell, San Francisco.

287,003.—NUT LOCK—F. H. Crawford, Redding, Cal.

287,256—ORE GRINDER AND AMALGAMATOR—Peter Eddy, Nevada City, Cal.

287,261.—BARBED WIRE FENCE—J. E. Evans, Spanish Fork, U. T.

287,374.—CAR TRUCK—Thomas J. Furbee, Bishop Creek, Cal.

287,118.—LAND MARKER—L. Gairaud, Santa Clara, Cal.

287,276.—SEWING MACHINE—Geo. Gowing, San Francisco.

287,377.—CABLE GRIP—A. Haman, San Francisco.

287,028.—INDICATOR PADLOCK—A. Jackson, San Francisco.

287,290.—INTEREST INDICATOR—H. E. Jenne, Ben Lomond, Cal.

287,307. CONVERTING MOTION—R. G. Moody, San Jose, Cal.

287,165.—BED LOUNGE—F. Rentschler, San Francisco.

287,166.—PHONOGRAPH—C. C. Reynolds, Prescott, A. T.

287,326.—DRILLING MACHINE—John Richards, San Francisco.

287,173.—ORE CONCENTRATOR—C. C. Rueger, San Francisco.

287,178.—CAISSON GATE—Geo. F. Schild, Vallejo, Cal.

287,198.—CRANK HANDLE FOR LIFTING-JACKS—J. M. Vance, Eureka, Cal.

287,202.—CAR AXLE—A. Walton, San Francisco.

10,658.—TRADE MARK—Franco-California Packing Company.

3,265.—LABEL—Pacific Vinegar Works, San Francisco.

NOTE.—Copies of United States and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

How to Recut Old Files.

To the Editor of The American Artisan:—

PERHAPS some of your readers may not know how to dress their old files and make them useful a second time. As a general thing, tinners' files become filled with copper, etc., long before they are worn out. By the following process files may be recut two or three times:—

Dissolve 4 oz. saleratus in 1 qt. of water, and boil the files in it for half an hour, then remove, wash, and dry them. Have ready in a glass or stoneware vessel 1 qt. of rain-water, into which you have slowly added 4 oz. best sulphuric acid, keeping the proportions for any amount used. Immerse the files in this preparation for a short time, or until the files are cut out clean. Then remove, wash in clear water and dry quickly, and put on a little sweet oil to cover the surface, after which your files are ready for use.

The same liquid may be used at different times, if required, by keeping it in a bottle in a cool place. As it is poisonous, it would be better to label it and keep it away from children.—*C., in American Artisan.*

ARCHITECTS who practice in the large cities will be interested in the answer given by the law editor of *La Semaine des Constructeurs* to a correspondent who asks whether the usual commission can be collected, where old materials are used in building, upon the cost of the work as it would have been if all the materials were new. The reply to this important question is a very satisfactory one, at least for architects in France. It appears that judicial decisions have established the law there that for his services in the construction of a new building an architect is entitled, in summing up the cost upon which his commission is calculated, to reckon all materials, whether old or new, and whether furnished by the proprietor or not, as if new and furnished by the contractor; the courts holding that the work and responsibility of the professional man, and his proper compensation, are the same in both cases. Moreover, if, as often happens in cities, the demolition of structures already existing on the ground forms a necessary preliminary to the construction of a new building, and if the architect of the latter includes in his service the direction of the work of taking down and sorting the old materials, and the provisions for the protection of the public, he is entitled in France, by a decision of the Tribunal of the Seine, to collect commission upon the cost of these operations, in addition to his fees for work upon the new building.—*The American Architect and Building News.*

Masons and Builders' Exchange of San Francisco, Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

Portland—Continued Building Prosperity.

ONE would naturally suppose that the building boom of the "Star City of the North" would, at this season of the year, fall off to a mere nothingness. The climatic conditions of the weather are such that the rain descends in quantities sufficient to almost stop building operations. That such is not the fact is evident from the following list of improvements now in progress. Our agent has sent us only the more costly, as a full list, containing all the small jobs, would fill more space than we can spare.

Six-story and basement brick for the N. P. P. R. Co.; *A.*, McKim, Mead & White; *C.*, W. E. Holmes for the rough stone work; cost of present contract, $100,000.

Third, corner D. Nicholi Bros. are having built a three-story and basement brick; *A.*, J. Krumbein; *C.*, Merchant & Bridges for carpenter work, and M. Owens for brick work; $20,000.

Third, corner Jefferson. Two-story brick; *O.*, J. C. Carson; *A.*, J. Lo Romer; $9,000.

Taylor, corner West Park. Architect W. H. Williams is superintending the erection of a $10,000 two-story and basement frame for J. R. Foster; *C.*, Sedge & Jenkins.

Eighteenth, near C. Two-story and basement frame; *O.*, L. Sechtem; *A.*, J. Krumbein; *C.*, G. Gardner; $6,500.

First, corner Clay. S. Harkins is erecting for J. Shade a two-story frame; $5,500.

West Park, corner C. Two-story and basement frame; *O.*, S. Loewengardt; *C.*, E. Kling; $3,500.

Fourth, near College. Two-story frame; *O.*, J. C. Curran; *A.*, G. Marshall, Jr.; *C.*, J. C. Wilson; $2,800.

Eighth, corner B. Two-story frame; *O.*, J. Stewart; *C.*, J. Mahoney; $2,000.

Hall, near First. Two-story frame; *O.*, F. Homstrom; *A.*, W. J. Graham; *C.*, E. F. Staley; $1,500.

North Fifteenth, corner S. Two-story frame; *O.*, M. B. Cook; *C.*, A. M. Young; $2,500.

Fourth, corner L, East Portland. First National Bank is having built a two-story brick; *A.*, Neer & Lo Romer; *C.*, J. E. Mayo; $9,000.

New Tacoma. Four-story brick; *O.*, Tacoma Land Co.; *A.*, McKim, Mead & White; *C.*, F. W. Lewis; $80,000.

Building News in Los Angeles and Vicinity.

Wilmington. One-story frame; *O.*, Mrs. Alexander; *A.*, Mr. Hall; *C.*, Mr. Gougeon; $2,000.

Celis. One-story frame; *O.*, Wm. Wheeler; *C.*, Mr. Hargett; $1,500.

Olive. City Horse Car Co., stables and offices; *C.*, Mr. Hargett; $4,000.

Bath. Two one-story semi-detached cottages; *C.*, Mr. Gougeon; $3,500.

Main. Two-story and basement frame; *O.*, T. E. Rowan; *C.*, Mr. Gougeon; $7,500.

Main. Two-story brick; *O.*, Foster & Brown; *C.*, not let; $35,000.

Los Angeles. Two-story brick; *O.*, Mr. Brown; $10,000.

Two-story brick; *O.*, Mr. Brown; $8,000.

Los Angeles, between Second and Third. Two-story brick; *O.*, Foster & Brown; *C.*, not let; $50,000.

San Fernando. Three one-story frame; *O.*, Arnold & Straton; *C.*, Arnold & Straton; $1,000.

Spring. Two-story frame; *O.*, Mrs. F. E. Howe; *C.*, Arnold & Straton; $3,000.

Hill. One-story frame; *O.*, W. R. Hasson; *C.*, Arnold & Straton; $1,700.

Hill. Two-story frame; *O.*, Mr. McCoy; $2,000.

East Los Angeles. One and one-half story frame; *O.*, Mr. Mathews; $2,000.

East Los Angeles. One-story frame; *O.*, Mr. Mathews; $1,800.

The above are under the superintendence of J. Hall, architect.

Pearl. Two-story frame; *O.*, M. Childs; *A.*, Chas. W. Davis; *C.*, J. Kindleburger; $8,000.

Spring. Two-story brick; *O.*, Mrs. M. Jones; *A.*, Chas. W. Davis; *C.*, J. Harget; $30,000.

Commercial. Two-story brick; *O.*, J. Bosseranie; *A.*, Chas. W. Davis; *C.*, B. F. French; $12,000.

Second, corner Fort. Presbyterian Church; frame; *A.*, Chas. W. Davis; *C.*, J. Webster; $20,000.

Main. Three-story brick; *O.*, L. J. Rose; *A.*, Chas. W. Davis; *C.*, W. H. Riggs; $30,000.

New High. Three-story brick; *O.*, L. J. Rose; *A.*, Chas. W. Davis; *C.*, W. H. Riggs; $10,000.

Los Angeles. Two-story and basement brick; *O.*, Smith & Heffner; *A.*, Chas. W. Davis; *C.*, D. Penman; $10,000.

Los Angeles. Three-story and basement brick; *O.*, Rece & Wessings; *A.*, Chas W. Davis; *C.*, D. Penman; $20,000.

Los Angeles. Two-story brick; *O.*, Harper, Reynolds & Co.; *A.*, Chas. W. Davis; *C.*, D. Penman; $8,000.

First, between Fort and Main. Two-story and basement brick (stable); *O.*, John Foster, *A.*, Chas. W. Davis; *C.*, B. F. French; $20.000.

Main. Two-story frame; *O.*, T. H. Rowan; *A.*, Chas. W. Davis; *C.*, W. H. Riggs; $5,500.

Main. Two-story frame; *O.*, W. Maxwell, *A.*, Chas. W. Davis; *C.*, W. H. Riggs; $7,000.

Fort. Two-story frame; *O.*, N. H. Moore; *A.*, Chas. W. Davis; *C.*, B. F. French; $4,000.

Pearl. Two-story frame; *O.*, Ex-Mayor Toberman; *A.*, Chas. W. Davis; $5,000.

Washington. One-story frame; *O.*, J. Dow; *A.*, Chas. W. Davis; *C.*, Mr. Pierce; $4,000.

New High. Two-story frame; *O.*, Mrs. Evarts; *A.*, Chas. W. Davis; *C.*, — Marsh; $8,000.

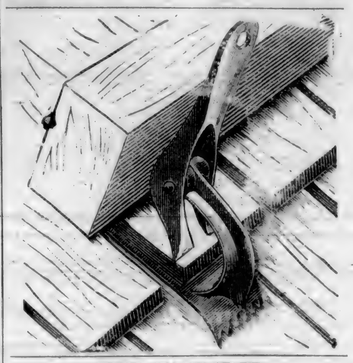
Anaheim, Drufus Block. Two-story brick; *O.*, Mr. Drufus; *A.*, Chas. W. Davis; *C*, S. Smith; $20,000.

Canada Canyon. One and one-half story frame; *O.*, A. W. Williams; *C.*, T. W. Cox & Farnell; $2,000.

Downey City. Two-story brick (Masonic Hall); *O.*, Franklin Bros.; $10,000.

San Bernardino. Two-story brick; *O.*, A. G. Burt; *A.*, Chas. W. Davis; *C.*, Ely Davis; $15,000.

KENNETT'S PATENT ROOF BRACKET.



NO MORE

Leaky Roofs.

Saves Time, Material, and Money.

Simple, Reliable, Durable, and Cheap.

THE BEST IN THE WORLD.

This Bracket is used to instantly secure a Scaffold or Staging on a Shingle roof,

Without the Use of Nails or Screws.

It is made of best **Malleable Iron**, and cannot be broken.

The above illustration shows the Bracket partly under a shingle and a scantling, in position. By this construction it forms a clamp, and the more pressure there is against it the tighter it gets. The bracket is placed over a joint, so that it holds on to three shingles and makes it doubly secure, and obviates any possibility of slipping or of splitting shingles.

The scantling lies close to the roof, so that loose nails and shingles cannot pass down and off the roof. It engages with thick or thin shingles with the same readiness and security.

It is the

Safest Mode

IN THE WORLD

OF FASTENING A SCAFFOLD.

It Cannot Slip or Give Way.

For Shingling, Repairing, or Painting a Shingle Roof, or in case of a fire to go on a roof it has no equal. It requires but a few seconds to change from one place to another, requires no nails, splits no shingles in taking up your scaffold, as in the old way; and thereby

Saves Time, Labor, and Money,

—AND MAKES A—

Stronger and Safer Scaffold.

We Have Been Appointed

Sole Agents for the Pacific Coast

FOR THIS BRACKET.

Price, $4.00 per Dozen.

In order that every mechanic on the coast may possess these Brackets, we will send a pair, post-paid, to any address, upon receipt of **75 cents.** ADDRESS

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

A square is 1 of an inch in length by width of the column. When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested, we do not send receipts.

Every architect in the State should insert his professional card in our columns, and thereby prove that he is endeavoring to assist in building up an architectural journal that will take rank with any printed. The charge is small. We want the influence your names will give, and we promise to spare no efforts in making the "California Architect" fully represent the views of a majority of the Profession on this Coast.

Retrospect of 1883.

THE END OF A REMARKABLY BRISK BUILDING SEASON.

THE end of 1883 is nearly at hand, and we have the pleasure of giving the results of perhaps one of the busiest years in the building intersts ever experienced in this city. Since the beginning of the year there has not been at any time an over supply of good workmen. On the contrary, contractors have kept up a steady growl at being obliged to employ any help they could get. Masons have, for the most part of the time, been very scarce, and have commanded $5.50 a day. Good carpenters have been steadily employed, and even at the present time, almost in the middle of our winter season, mechanics are generally engaged.

The building of "flats" still continues, and the demand more than equals the supply. From present appearances, next year will exceed this in the number of this style of residences. Many are following the ideas of a prominent capitalist — making the internal arrangements convenient and neat, with but little attempt at ornamentation, the front elevation, however, having the appearance of a magnificent mansion. Thus even a mechanic, with all the uncertainties of bad health and lost time, can afford to live in a dwelling, the equal, in looks, of the more aristocratic business man.

We append a monthly statement of the building operations of this year:—

	Frame Build'gs.		Brick Build'gs.		Repairs and Alterations.	
	No.	Cost.	No.	Cost.	No.	Cost.
January	31	$293,80?	2	$105,000	8	$76,000
February	39	87,2 9	1	18,000	14	27,010
March	38	198,900	2	30,000	18	68,700
April	71	279,985	1	20,000	12	34,900
May	53	283,500	7	161,700	10	41,400
June	100	439,535	11	85,600	16	48,450
July	66	288,500	3	101,270	9	30,000
August	65	257,300	6	140,500	14	73,600
September	41	373,100	3	163,500	8	31,300
October	27	145,000	..	.....	8	21,600
November	43	396,500	1	10,000	12	56,600
December	42	172,150	5	152,700	16	69,875
Total	616	$3,215,649	42	$988,270	145	$579,435

By the above we see that the total number of building improvements of all kinds amounts to

803 Buildings of the value of $5,261,689.

For the sake of comparison we give the figures for the three preceding years:—

YEAR.	BUILDINGS.	VALUE.
1880	397	$1,754,435
1881	533	3,790,732
1882	785	3,896,212
1883	803	5,261,689

Most certainly this is a splendid showing. Several improvements under way are not counted in the above. The Flood mansion is only given credit for the amount spent in this city, no account being taken of contracts let to Eastern parties. The large improvements by the Union Foundry in South San Francisco, are not included. In fact we aim solely to give the number of buildings and the cost thereof, without including the cost of machinery, or the cost of filling in the tide lands, piling, etc., so necessary in some places before buildings can be erected, but which we do not think ought to be included in the estimate for buildings.

Building for 1884 promises to be remarkably brisk, and we think will exceed this year in number and value.

We tender our sincere thanks to those who have so nobly aided us in building this journal to its present standard. The future looks more than bright, and we promise many new improvements in our January issue.

We must congratulate carpenters all over the State in the possession of such good helpmates. This year we have received many letters containing money for first-class architectural and mechanical works, to be used for Christmas presents from the wife to the husband. We are pleased to see this, as it is through study that the mechanic gains the knowledge necessary to overcome the difficult problems daily presented in his daily avocation.

Wishing all our readers a full enjoyment of all those blessings usually experienced at this season of the year, and tendering our heartfelt thanks for their support, so generously given the past year, we close our labors for 1883, and with energy and hope for our watchword, we look forward to 1884, confident that we will excel our past efforts.

NEW METHOD OF PREPARING BLOCKS FOR ENGRAVERS.—At a recent meeting of the Chicago photographers, Mr. Shaw showed the members present his mode of preparing blocks for engravers. He claimed that it was very simple and easily worked. He commenced by breaking an egg, and pouring a little of the albumen on the block, and then thoroughly rubbing it in. It does not sink into the wood. His preparation, which is kept on the surface all the time, is as follows: gelatine, ten grains; albumen, one ounce; water, one-half ounce. Rub this well in with the palm of the hand or a brush—the hand preferred; after this preliminary coating put on a little photina preparation, which is also to be well rubbed in. In five minutes a print from a negative can be taken on this block in the sun, or by the electric light in about three minutes. The process gives good black tones, like those obtained in platinum prints.

S. F. Chapter, American Institute of Architects.

THE regular monthly meeting was held on Monday eve, Dec. 10th. T. J. Welsh occupied the chair.

Committee on Incorporation reported that all necessary measures had been taken to effect said result, and they were simply waiting for a seal to be furnished, in order to complete their work.

Committee on Ammendments to the Plumbing Law asked for further time, as it was their earnest desire to have the work well done.

Warren H. Williams was proposed for membership. Application referred to the usual committee.

Communications were received from the Sect of the American Institute of Architects, which after being read were placed on file.

A communication was received from the managers of the CALIFORNIA ARCHITECT AND BUILDING NEWS, stating that it was their intention to offer four prizes—one of $60.00, one of $50.00, one of $40.00, and a box of drawing instruments—for the best four designs for a country dwelling, to be published in said journal. The managers requested a committee be appointed by the Chapter to determine the relative value of the drawings submitted in the competition. The president appointed the following named Fellows as the committee: Messrs. Sanders, Pissis and Mitchell.

A short discussion ensued upon the stand to be taken by the Master Masons and Builders' Association on and after January 1, 1884. It was the opinion of a majority of the members that, although at first it might seem awkward to make separate contracts for amounts slightly in excess of the amount adopted by the Master Masons, yet, in a little while, harmonious feelings between all the trades may be secured by just and impartial action among those most interested.

(We do not see why the masons have not the perfect RIGHT to the same privileges as are enjoyed by the carpenter contractor. One has as just a claim as the other in being the contractor of the building. But few carpenter contractors would take a job having the master mason as a principal, and why not *vice versa?* In many cases the cost of the brick work exceeds the carpenter work, and we do not understand why the latter class should be recognized as the supreme head of the work as far as the contract goes, collect all the payments, and pay the amount due the mason, the latter being a second party. In case of a failure of the principal contractor it is always the sub-contractors who have to stand the loss. The principal draws the money, and in dividing it to meet all the requirements of a contract he oftentimes remembers his own pocket first. We hope this question will receive a discussion between the parties most interested, and we will with pleasure publish such views as may tend towards a harmonious settlement of the questions involved.—EDS.)

Trade Discounts to Architects.

FOR some time past it has been the custom of manufacturers and dealers to allow architects a plunm generally known as "*the trade discount.*" This is done when the articles are ordered directly by the architect, and the justification of the offer is made upon the fact that the discount is always at some one's service; the builder is not entitled to it, he merely places in the building articles ordered by the architect, consequently the only one to profit is he who gives the order. Another reason advanced for the offer is that an architect often has considerable trouble in examining the different inventions and manufactures of the same class, and no matter what his selection may be he is justly entitled to the "*trade discount,*" being the only one who has had any trouble in the matter.

The question has been asked us, Are architects justified in accepting the offers thus made? Also, What stand does the Institute of Architects take upon this subject?

"The Institute of Architects has from its foundation opposed the practice in toto as a point of honor, holding it to be manifestly inconvenient that the supervisor of building works should upon any pretence be allowed to involve himself in the supply of articles, the quality and price of which he is employed to check in the interest, the purchaser of his client. At the same time it is only fair to add that there are thoroughgoing men of business, as business goes, who still maintain the arguments first mentioned to be sound, and who fail to see why an invariable trade discount should be lost, or why an architect should spend his time upon the selection of cheap articles of taste without remuneration.

"To this, however, the principle adopted by the Institute would still seem to have an answer to give, namely, that whenever any special remuneration is due, it ought to be paid directly by the employer, who it may fairly be supposed, if he be one of those who prefer to take a tradesmanlike view of such matters, will be found ready to indorse his own opinions.

"The practice mentioned is one which we must expect to see developing itself more and more as the times change and the ways of business change with the times; but there are certain principles which ought never to be lost sight of in a profession like that of architectures, such as these: That whatever is done must be done openly and above board, and that no payment can honorably be received except for work done by the recipient. The necessity for acting under any circumstances in any sort of underhand way we wholly deny."

Black Walnut.

BLACK walnut can be grown from the nut, producing a butt fourteen inches in diameter in as many years from the seed, as far north as Massachusetts. No tree valuable for its timber in cabinet uses, unless the black birch be so considered, can attain to that useful growth in that period of time in our northern climate. Maples require twenty years before they become good timber trees; beeches and birches, fifteen years to attain to a diameter large enough to yield nine-inch boards; hickory should have a growth of thirty years; and cherry at least as much.

The cultivation of the black walnut might be made a source of profit, if only as an auxiliary to the ordinary farm products. It requires no particular care, makes an elegant tree even in its youth, and later offers an agreeable shade. The *Sewing Machine Journal* says:—

"One hundred acres of land, seeded to walnut trees, even if they reached maturity in fifteen years, would be more remunerative than many of the crops produced by fifteen of incessant toil. Besides, these trees might be planted and would thrive on spots which are really valueless for agricultural purposes, and while in the course of growth would serve as valuable aids to agriculture as wind-breaks and in other respects."

Our Exchanges.

WE have made arrangements with the editors of the following journals, by which we are enabled to offer quite a reduction to any one subscribing for any one of them in connection with this journal.

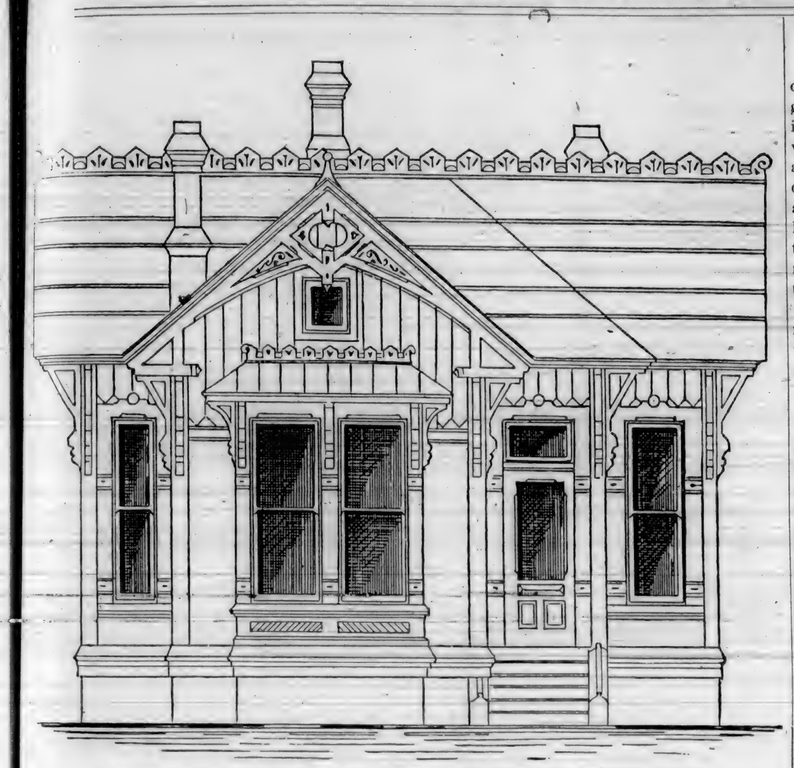
(The figures in parenthesis denote the price of the journals alone.)

CALIFORNIA ARCHITECT AND BUILDING NEWS.
Terms, $2.00 per annum.

With *American Architect* ($6.00), $7.00 per annum.
With *Builder and Wood Worker* ($1.00), $2.50 per annum.
With *Carpentry and Building* ($1.00), $2.50 per annum.
With *American Artisan* ($1.00), $2.50 per annum.
With *Brick, Tile, and Metal Review* ($1.00), $2.50 per annum.
With *Building* ($1.00), $2.50 per annum.
With *North Western Lumberman* ($4.00), $5.00 per annum.
With *Scientific American* ($3.20), $4.50 per annum.
With *Leffels' Mechanical News* ($1.00), $2.50 per annum.
With *Decorator and Furnisher* ($4.00), $5.00 per annum.
With *American Machinist* ($2.50), $4.00 per annum.
With *The Wood Worker* ($1.00), $2.50 per annum.
With *The Builder* ($2.00), $3.50 per annum.
With *American Inventor* ($1.00), $2.50 per annum.
With *Hall's Journal of Health* ($1.00), $2.50 per annum.
With *Cincinnati Building Review* ($1.00), $2.50 per annum.

We will add to the above list from time to time, as our arrangements are perfected with the publishers. We are prepared to furnish any journal printed at the shortest possible notice.

All communications intended for M. J. Marion may be left at the office of his journal. We have received quite an interesting communication from him, but too late for this issue.



FRONT ELEVATION OF COUNTRY HOME, COSTING ABOUT $2,800.

A Country or Suburban Home.

THE accompanying plans are intended, if carried out according to the designs shown, to give a very comfortable home for a small family. Its special features are well-lighted and ventilated rooms, closet room in abundance, and conveniences generally needed in this class of house. The w. c. is placed outside, and yet is easy of access. Bath room is well lighted, and the window is so placed that thorough ventilation is secured. If desired, the mullion shown in dining-room may be changed to a square bay window, similar to the parlor.

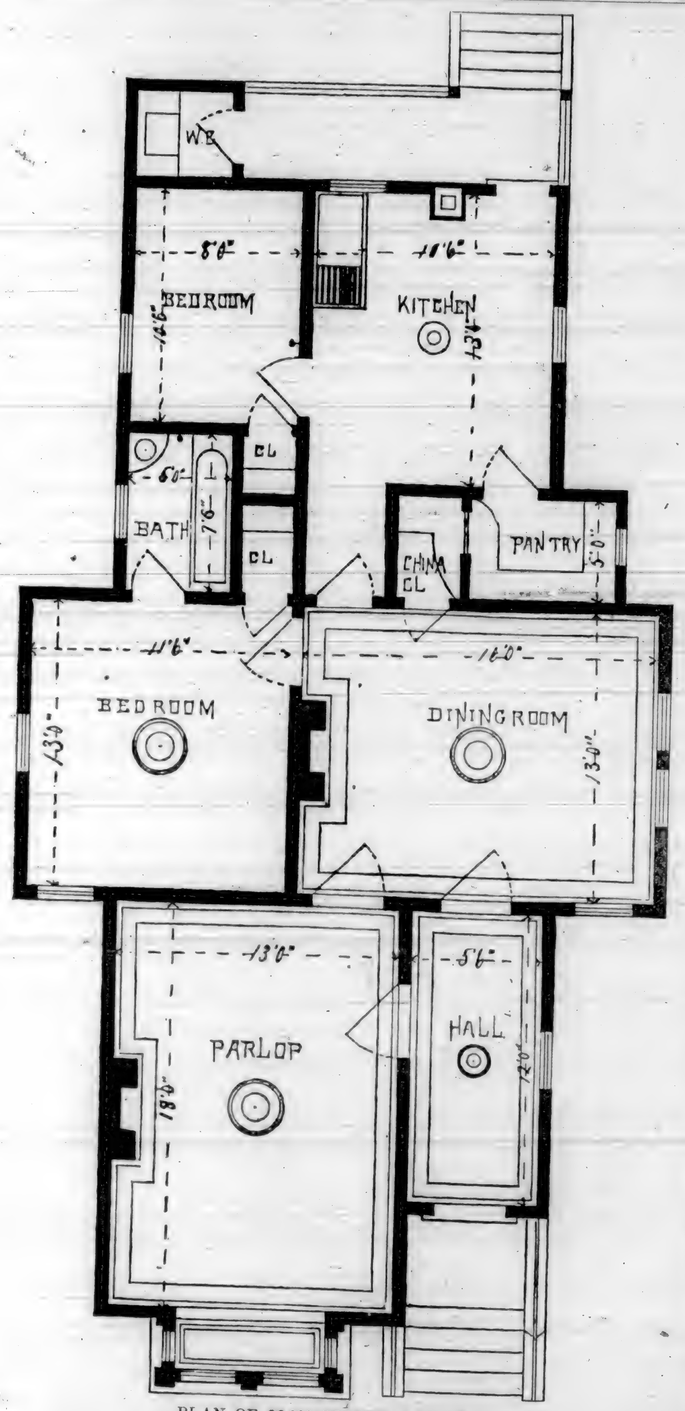
The plan carried out as shown, can be built for about $2,800. This figure may be greatly varied according to style of finishes used.

Cost of Buildings.

WE frequently receive letters containing queries in regard to the cost of buildings, the plans of which have been given from time to time in this journal. Prices vary at different seasons of the year, and those given in the description of plans are the prices for which the buildings could have been erected *at the time of the issue of the Journal containing the plan.* About twenty-five per cent. would have to be added on the estimates given in 1880, 1881, and part of 1882, to correspond with prices at the present time. By comparing price lists, and allowing the difference, a correct idea may be gained of the different values.

AN old but good idea, and one not generally known, is to line the jaws of the vise with sheet lead when clamping saws for filing. If not so lined, the saw will vibrate and probably strip the file.

SIDE ELEVATION OF COUNTRY HOME, COSTING ABOUT $2,800.



PLAN OF $2,800 COUNTRY HOME.

Beware of Creating False Impressions.

The sound of saw and hammer is heard on all sides, and every man that can handle tools is pressed into the service, to meet the grea' demand for new buildings.

The above *in italics* is the gist of numerous articles selected from various country papers that have found their way to our sanctum, and we have purposely placed the words in a prominent position so that parties interested will have their attention drawn thereto.

A country paper to be successful must pay strict attention to the affairs in its immediate neighborhood. It is taken by people living outside of its jurisdiction, that they may keep the run of the local affairs of the town in which it is situated. When the news contained therein is found to be always reliable, it often receives subscribers from sources seemingly at variance with the object of the paper. We propose to speak of a few things in one interest only—that connected with building improvements.

In making statements in regard to new buildings, alterations, or other improvements, be sure that the true facts are stated and in a way not to mislead. A worthy mechanic called at our office not long since, and asked our opinion in regard to locating in a certain town. He had in his hand a local paper of the last issue prior to his call. To read the statements made therein one would imagine there was an immense building boom being experienced. Mr. A was erecting a business block; Mr. B, a comfortable dwelling; C, D, E, and F were making large additions to their barns. Lumber was being hauled for several buildings soon to be started. In fact the sound of saw and hammer was heard on every side, and men could not be had to do the work.

While our visitor was reading, his listener was simply dumb from astonishment. But a few days before we had been through that same town. The business block of Mr. A was 28x40, one story high, rustic front, sides boarded with rough lumber placed endways and battened, divided into two stores, separated by a board partition. One store was intended for a saloon, and the other anything it would rent for.

Mr. B's comfortable dwelling was 12x24; simply a two-room house, boards on end and battened. The large additions to the barns were simply sheds to cover the wagons, etc.; the lumber for the new buildings was similar to that necessary for buildings of the above description.

No doubt to the editor of that paper the work in sight was enough to make him eloquent in praising the business activity of his town. But he should have looked a little deeper and taken into consideration the fact that others besides his own town people read his paper, many of whom were on the lookout to locate in places where a reasonable activity prevailed. Reading the local notices as given, a mechanic would be justified in visiting that locality for the purpose of inquiring into its claims as a business center and offering special inducements to the man who wieldeth the saw and hammer truly and well.

We could cite many instances where parties have been misled by the glowing accounts given by local editors, of immense improvements shortly to be commenced. It is not our purpose, however, to recapitulate. We would simply draw the attention of those who have charge of the local department of the various country journals, to have your statements so plain that there will not be the slightest chance of any one misunderstanding them. If possible give the *cost* of the improvements underway; for it is by this that the mechanic judges of the class of work being done. A business block costing probably a $1,000 would convey at once to his mind just the kind of a *block* that could be erected for that amount of money, and he most certainly would not spend even a four bit piece for fares to get a job on such a *block*.

Remember that mechanics visit the libraries, reading-rooms, etc., especially to get information in regard to building in process of erection all over the State. Since this journal has endeavored to give reports from so many sources, our offices, at times, have been thronged with men inquiring for the best places to locate. Our information is largely obtained from a perusal of our many exchanges. Not wishing to lead others astray, we are ourselves not desirous of being wronged through reading a too glowing account of building improvements.

The Employment of Better Mechanics the Result of High Prices of Materials.

It may seem an anomaly but it is a fact that during the reign of high prices of material the contractor invariably seeks the high priced mechanic, and his reason for so doing is found in the fact that first-class mechanics are less apt to make mistakes and thus the waste of material, so common amongst inexperienced men, is greatly lessened if not almost wholly overcome.

When lumber, for instance, is cheap, or even when it is at a moderately fair rate, the contractor seeks to get the most work done at the least expense. On large jobs, even laborers are substituted in passing lumber to and fro. Apprentices are set at work doing that which should belong to the experienced mechanic. A few feet of lumber don't amount to much, and so but little attention is paid to the blunders made.

When, however, lumber is four and one-half cents a foot for surfaced and the finer grades, it becomes necessary for the principal to look after his employees, as it does not take the cost of but a few boards spoiled in cutting to more than offset the difference in wages.

High prices of material are a death blow to *piece-workers*. It is a notorious fact that these have-to-be-endured men are without consciences in their waste of material. If a floor is to be laid, their motto is simply anyway to get it laid. Rustic is cut with but one idea in their mind, to get it *planted* on as quickly as possible.

The same remarks are applicable to the plasterers and brick-masons' trade. We have been in buildings where the mortar was almost as thick on the floor as it was on the walls. This fact at once shows the inexperienced workman. It is surprising to note the number of half bricks that are found around some buildings. We do not by any means advance the idea that half bricks are equal to whole ones, but we do say that a good workman would so place them in a wall that no one could tell that they were used.

We were much amused the other day at watching a greeny building a chimney. Half bricks were tossed into the lot adjoining only to be picked up by poor Pat to be carried up the second time. The excuse the master (?) chimney builder gave us for throwing away every half brick was that it made too many joints, the one on top of the other.

First-class workmen always have been and always will be the cheapest in the end. In order to obtain their proficiency they must need study, and therein lies the fault of the cheaper men, they have no time to study. A journal devoted to their interests never receives their subscription, as they can never find anything in it excepting what they already know. To all such we would say, if such be the fact, suppose you try a change. Your old way evidently has been a failure, or else you would be receiving better wages. No matter what part of the country you live in, subscribe for and support your home journal published in your interests. Study it well; practice the good advice given, and in a short time you will be able to command the wages justly due to those who study the science of the various mechanical trades.

Hanging Paper on Damp Walls.

The Germans are utilizing a discovery for hanging paper on damp walls. It consists of coating a lining paper on one side with a solution of shellac spirit, of somewhat greater consistency than the ordinary "French polish," and then hanging it with the side thus treated to the damp wall. The paper-hanging is then performed in the usual manner with paste. Any other resin that is equally soluble in spirits may be used in place of the shellac. According to the representations, this process is found equally effective in preventing the penetration of dampness.

Glycerine Glue.—A German chemist has discovered that the strength of glue is very greatly increased by the addition of one-fourth as much glycerine as glue.

Glycerine has many other uses, among which one of the least known is its property of removing pencil marks from paper in a very perfect manner. It may also be combined with starch and plaster of Paris, to form one of the most durable cements for various kinds of apparatus.

Cottages and Villas. Price $6.00.
Practical Carpentry. Price $1.00.

Competition Designs!

ONE HUNDRED AND FIFTY DOLLARS

Cash Premiums!

FOURTH PRIZE,

Box of Drawing Instruments.

In order to promote a general desire to excel among Architects and Draughtsmen in the preparation of drawings for this Journal we have concluded to offer the following premiums for the best 4 designs of a Country Dwelling, the successful plans to be published in the California Architect and Building News.

1st, a Cash Prize of $60.00
2d, " " 50.00
3d, " " 40.00
4th, Box of Drawing Instruments.

Plans are to be for a house costing about $5,000. Front and side elevations to be shown, with plans, and a detailed estimate of cost.

All plans to be in the office of the California Architect BEFORE the 1st of May, 1884, in order that they may be presented to the S. F. Chapter American Institute of Architects at their regular meeting on May 2.

The Chapter appointed the following Fellows as a Committee to decide upon the merits of the respective designs submitted:—Messrs. G. H. Sanders, Albert Pissis, and H. D. Mitchell.

We make the above simply as an announcement of our intentions. Our January issue will contain full particulars in regard to the competition. We will be pleased to receive the names of those desiring to compete.

Address all communications in regard to the above to the Business Manager of this Journal, 240 Montgomery Street, S. F.

Country Architecture.

BY A. CURTIS BOND.

OUR illustration this month shows a sea-side cottage, erected during the past summer at Coney Island, one of the near-by bathing resorts of this city. The front we have shown is that facing the sea, the entrance being at the opposite side and looking upon the road. I would say that the small room opening upon the space beneath the bay-window and directly behind the post, as shown in the drawing, is used, in this particular house, as a dressing apartment, where the occupants of the house may prepare for the bath and run down to the surf, which is at the foot of the grounds, but a short distance away.

SPECIFICATIONS FOR SEA-SIDE COTTAGE.

MASON WORK.—Excavate for foundation three feet below present grade on water front, and one foot on road front, and twenty inches around walls for a stone footing course, also excavate for drain, etc., to connect with public drain; all sand and earth so excavated to be used for grading around house when finished.

Foundation to be built within six inches of grade, with good foundation stone, and center wall to be built up within ten inches of first floor to set floor beams on.

BRICK WORK.—All exterior work to be laid up with best quality face brick laid in red mortar. All inside brick work to be of good quality brick, well laid and neatly pointed. Chimneys where topped out above roof to be of face brick.

STONE WORK.—A neat sill of at least twelve inches to be put around entire house. Corners and trimmings of windows, as shown in sketch, and base and caps of chimneys to be of good quality. Sand or brown stone with neat sunken carving over windows as shown in sketch, column of bay window as shown, base and cap of column to be of above kind of stone, shaft of aberdeen granite, neatly polished to show grain between trimmer on first story; to be laid with rough stone neatly pointed with white mortar to show joints. Blue stone steps to first story under veranda.

PLASTERING AND LATHING.—Lath with good quality spruce laths well nailed—then plastered; good coat of mortar for brown coat, then a finishing coat; the first and second story to have hard finish; all the principal rooms on first and second story to have neat cornice, to be selected by the owner, also center as may be selected.

All mason work to be done in a workmanlike manner, and all material used to be of good quality as the market can supply.

TIMBER.—CARPENTER WORK. All floor beams to be 2x10 and to rest on brick wall at least four inches well bridged with good 2x3 spruce bridging, all studs to be 2x4, and all brick walls to be furred with good two-inch furring strips well nailed to joints of buctm.

DOORS AND WINDOWS.—Door and window frames to be made in the usual way of good seasoned one and one-fourth pine, windows to be hung with cord and pulley, and latest pattern of sash fasteners, windows to be glazed with French plate glass in four lights as shown on sketch; all main doors to be one and one-half inch thick with neat panels, except closets paneled on one side only, front door to be two inches thick with raised panels, all to be neatly trimmed with neat moulded pine trimmings.

STAIRS.—Stairs where shown in plan with circular railing. Newel post at foot of stairs of such design as owner may select, with neat moulded hand rail and baluster neatly trimmed. All to be of black walnut.

OUTSIDE TRIMMINGS.—Bay windows where shown, with neat balustradi on top with turned balustraden brackets on angle of corner, with panel at base and arch brackets resting on stone column, a neat balcony on gable over bay window with balcony, with cross braces for balusters and with neat brackets to support all. Gable ends to be finished as shown with open scroll work in angle of circular truss; all to finish with tipe neat brackets where shown on sketch for gable corners. Neat, galvanized, and gold tipped finals on all peak of roofs, of good neat style. Neat veranda on front with baluster around, and good stairs leading to grade.

WATER CLOSETS.—Where shown, set with bowl and trap with flush closet, the waste-pipe to connect with sewer.

PANTRY.—To be fitted up with shelves and drawers.

CLOSETS.—In chambers to have neat six-inch strips with hoses.

FIRE-PLACES, ETC.—Ranges set in kitchen with the necessary appliance for hot and cold water. Dining-room and parlor to have grates set in, with brass fittings, these two rooms to have marble or slate mantles as may be selected; all other rooms to have wooden mantles.

ROOFS.—French and slanting roofs to be covered with good quality blue slater, well nailed; French roof put on top to be covered with good quality charcoal tin, with ridges raised about ten inches apart, to regulate flow of water.

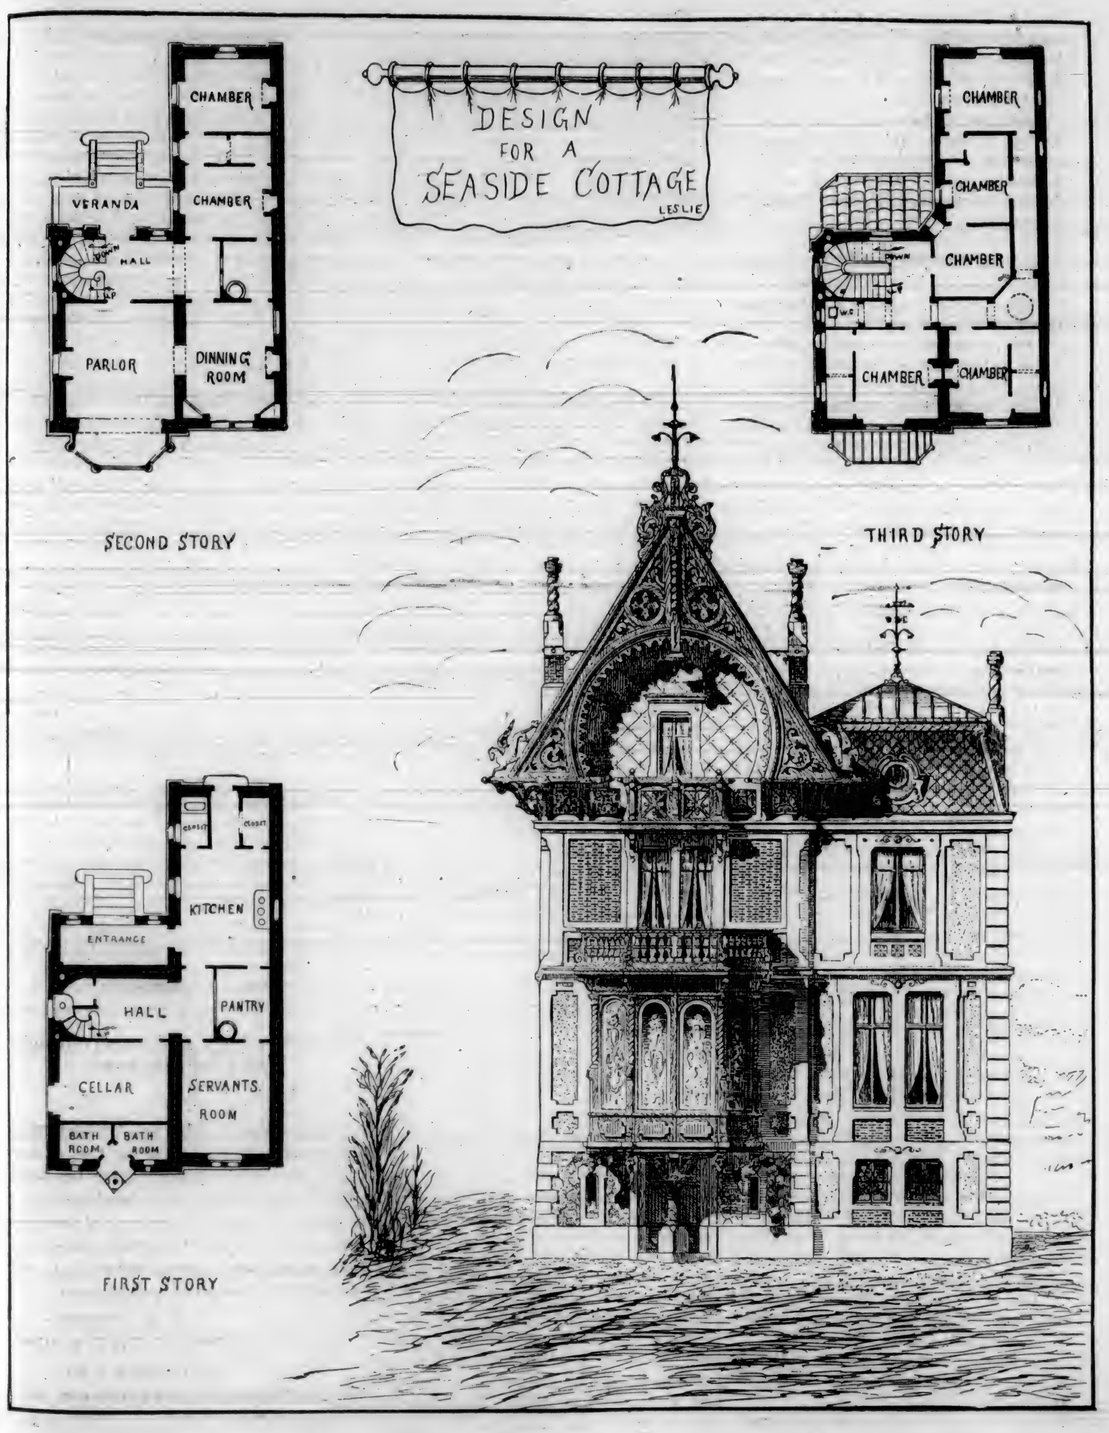
All the work to be done in a workmanlike manner and good material used.

I presume every one is more or less interested in protecting his house against lightning, and upon this assumption by the New York architects, there has been carried on recently a general discussion as to the best method of protecting country houses, or in fact any buildings liable to be struck, from the disastrous effect of a thunder storm. It had become an occurrence of too frequent regularity in and about the city, and it was considered wise to devise some means to avoid it. The foreign architects have had their say in the matter too, and the result of their conferences seemed to bring them back very near to the point from which they started. There is no doubt that an exposed position, or a building with a great deal of metal in its construction, offers an opportunity for the lightning that it seldom misses. One instance within my own knowledge shows this. It is that of a church built upon a high hill; was struck no less than five times in one year, and kept on being struck until a rod was put upon it, a precaution that at first was violently opposed by the minister, who had, it seems, an unaccountable sort of a conceit or lunacy that the holiness of the edifice would be a sufficient guarantee of its permanency.

We cannot consider this question upon the basis of how and where houses *should be* built, but how and where they *are* built. For one person who would avoid a picturesque site from the fear that it might prove attractive to lightning, ninety-nine would select the spot for its other advantages. And for one person whose design for a house would be controlled by electric considerations, there would be an incalculably larger number who would regard economy, fashion, convenience, custom or other motives as determining the style of architecture they would adopt.

Metal enters, more or less, into every house, and it must be observed that it is rather the extent of metallic surface than the bulk that attracts the electricity. An instance is given where a shaft entered a house, tore the gilding from the cornices, twisted the moulding rod, partially fused the wire of the bell pulls, and yet avoided the inmates, of which at the time there chanced to be a goodly company. Smoke has conducted lightning down the chimney, and thus out through the fire-place into the midst of the occupants.

The first point therefore to insure safety in a dwelling-house is to complete the metallic connection of all metallic surfaces of any extent, on or within the building, the necessary connection being not only with each other but with the earth. At the same time it is desirable to protect the salient points of the house, such as pinnacles, gable-ridges, and, above all, lofty chimneys with metallic points, somewhat elevated above the rest of the building and in perfect connection with the earth. Some parties claim that these points should be elevated ten feet, others say thirty feet, and others only five feet above the point to be protected. But I think the settlement of this difference rests entirely upon the theory which attends the use of the rod, if it is for the purpose of attracting the lightning and thus s oner terminating the electric storm, then possibly the higher rods may be preferable, but if the project is merely to protect the house if struck, and divert the current from the inflammable portions, then the ordinary s ort points are all that is necessary. The clouds are often quite near to the earth, in which event every foot of rod is valuable, but if the normal condition of things be taken and the clouds are 1,000 or more feet from us, it is doubtful whether a score of feet even would make any material difference. It has been a mooted point whether the metal rod should be connected directly with the building or if it were not better to insulate it. It is claimed that the insulated rod is rather an attractor of the flash, and thus a means merely of diminishing the ærial electricity, than a house protector. There is one thing certain that during an electric storm the metallic substances in the



house will become charged, and if no means are adopted to draw off this charge, the danger is considerable and it is not certain that this danger would be averted by an external rod isolated from the house.

Bearing in mind, then, as it is necessary to do, the manner in which all conductors, in connection with the earth, become charged in a thunder storm, I think there can be no doubt of the propriety of metallic connection throughout.

Amateur Architects.

"WHAT is another one of the disagreeable things which besets you?"

"The patron who comes into your office with a plan he has 'made all by hims lf' and wants you to follow it. You ask him if he made the drawing to a scale, and he admits that he has not, announcing at the same time that won't make any difference, as he knows just how much room he has got and has planned accordingly. Then you suggest that nothing can be told from his drawing as to how the building will look, and he, getting mad, tells you to go ahead and if it does not look all right it will be his fault." "That's fair enough if he takes the blame."

"He'll take the blame soon enough, but he kicks like a steer when, after we have made a drawing to a scale, he finds his plan a failure, and that we ask pay for humoring his fancy. Why it would just break you all up to see some of the amateur plans and designs I have in my office."

So saying the architect escorted the reporter to his office, and fixing him comfortably in an arm chair, placed before him a large portfolio filled with amateur efforts. They were very interesting, embracing all classes of architecture from the Gothic and Gothic-Normandi to the most unique combinations of Grecian and Græco contours. Talk about the Detroit high school building, it is a nonentity compared with most of these efforts. Scale! there was none; but efforts at harmony and originality were visible everywhere. One particularly striking effect was shown where a dwelling house, having thirty-two feet of frontage, was concealed behind a portico sixty-one feet (according to the width of the building as shown in the plan) high and forty-four feet deep. Another charmingly original idea was a house with a front door sixteen feet wide, and windows eight feet wide, and a two-story house at that. Another plan, the designer of which evidently wanted an observatory, showed a cottage with a tower 116 feet high, according to the scale to which the draughtsman unconsciously worked. And so on, were discrepancies without number, and all of them ludicrous beyond measure.

"Just fancy trying to do something with this," said the architect, laying a drawing in water colors in the reporter's lap.

The plan, evidently the work of a lady, gave, in perspective, views of two sides of a proposed dwelling house.

If it were possible to build according to the design there would be a house of cut stone, with a double arch at one corner resting on two stained glass windows, each twelve feet wide, while a very early English chimney would pass through the arches and windows to a point in the basement, through which a doorway had been cut. Finally, surmounting the heavy stone arches which rest on glass supports, would be a tower balcony eight feet high and twenty-four feet square.—*Press Interview.*

"LA SEMAINE DES CONSTRUCTEURS" gives its opinion in a recent number upon a question which will interest a great many people besides its own readers. A letter to the editor relates that the writer, a clerk in the office of his father, who is a mason and builder, was asked by a thrifty individual to make plans for a building which he thought of erecting The clerk made the plans and took them to the proprietor, who found them satisfactory, and desired that specifications should be drawn up, and the whole submitted for estimate to such contractors as the clerk might select. This was done, but on comparing the estimates it was found that the total estimate exceeded the limit of cost which the proprietor had contemplated; and the plans were modified to lessen the expense. The remodeled drawings had been made nearly satisfactory to the proprietor, and a final consultation was held between him and the designer, at the close of which he requested the latter to lend him tracings of the plans, in order that he might consider them a little further by himself. The clerk unsuspiciously did as requested, whereupon the proprietor had the drawings traced, and, sending back the originals with an insulting letter, proceeded to submit his stolen copies to another contractor for estimate, saying that the plan had been made by "one of his friends." The second contractor happened to be a relative of the clerk, and learning the circumstances, or recognizing the plan, took the liberty of putting the tracings in a place of safety, for restoration to the rightful owner.

THE inquiry which the clerk makes of the editor of *La Semaine* is, whether he can collect payment for his work on the plans and specifications, and, if so, at what rate? The reply is, it must be acknowledged, anything but encouraging to persons who desire to combine in themselves the functions of architect and contractor. In the editor's opinion, a proprietor who requests an architect to prepare plans for him implies in that request a promise to pay him the customary compensation for his trouble; and the architect, like the member of any other profession, has only to prove employment in his professional work to recover the usual remuneration. With a builder's clerk the case is very different. His business is not to make designs, but to help his employer in securing and executing contracts; and neither the proprietor nor other persons would ordinarily see, in the fact of his preparing plans and specifications for a building, anything more than an effort on the builder's part to make sure of a contract which he might lose in the chances of competition if an architect were employed in the usual way. That this would be the ordinary understanding in such a case, in default of any agreement or stipulation to the contrary, is shown, as the editor thinks, by the simple consideration that no one, if it were customary to pay architects' fees to builders' clerks for such work, would choose the inexpert and irresponsible service of the latter in preference to the educated taste and skill, and greater pecuniary responsibility of the professional man. The editor is further of opinion that the preparation of plans and specifications by a builder's subordinate not only do s not entitle the latter or his employer to compensation, but furnishes no ground for claiming a preference in the award of the contract; the understanding in such cases being, as he thinks, that the plans are made simply as an inducement to the proprietor to enter into the contract for their execution. They may accomplish their object, if the builder is fortunate, but if not, he is only entitled to his labor for his pains.—*The American Architect and Building News.*

A RELIABLE estimate lately made upon a certain quarter section of redwood timber in California was 32,000,000 feet. In comparing this with the pine lands of the Saginaw, Mich., district, it is stated that 2,000,000 feet was an extraordinary growth on the best of the land, when good forties were plenty, and 100,000 feet to an acre is called the biggest yield on record in the Saginaw region.

A NEW slate pencil sharpener introduced by a Chicago firm is merely a six-inch rule with V-shaped groove on two sides; they are thoroughly coated with the purest emery, and a hundred slate pencils may be reduced to powder by one of these little instruments before it is worn out. The price is so low that they can be given away as advertisements, the dealer's name being printed on them gratuitously if ordered in sufficient quantity.

PYATT'S PATENT ILLUMINATING ROOF AND ROOF BASEMENT.

Three different kinds of Artificial Stone Illuminating Tiles, as well as that of Iron made by the Undersigned, under the Hyatt Patent, with Jackson's Patent Improvements.

Owners of property using any of these improvements, as well as the makers thereof, unless manufactured by the undersigned, will be liable for damages for infringements.

P. H. JACKSON,
Attorney for Mrs. E. A. Hyatt,

P. H. JACKSON & CO.,
No. 2 California Street and 231 First St., S.

Two Dollars Per Annum.

WERE it reasonably possible to place the subscription price of this journal at a lower rate than two dollars per annum, we would cheerfully do so. But, in this city, we labor under many disadvantages not experienced by Eastern publishers, and which render it impossible to adopt a lower standard of subscription rates. The outlays to be encountered in this field of operations do not present themselves in other places, and it requires infinitely greater labor and expenditure to accomplish like results with those produced where all the surroundings and facilities are favorable and easy.

We think all our readers will notice the gradual improvement we have been making in regard to furnishing superior engravings. It has been our most earnest desire to introduce the improved process of photo-engraving, now so successfully worked in the East. In regard to the cuts made by our own process, the first representations of which will appear in our January issue, we would say that it has been the result of much study and perseverance, and we intend to so improve upon it that it will be unnecessary for any one to send drawings to the East for reproduction.

Every architect, draughtsman, student, and builder should possess a copy of this new work. Those parties not members of the profession, who are occasionally called upon to direct building operations, will be greatly benefited by a careful study of this work We will send a copy of the above, and one year's numbers of the CALIFORNIA ARCHITECT upon receipt of $5.00.

What Do You Think of It?

THE *American Cabinet Maker* notes a recent interesting legal decision. A cabinet maker in Michigan, in a written contract, agreed to make a walnut counter for one of his customers, but instead of using solid wood he took for the top and door panels, whitewood, and stained it to imitate walnut. The customer refused to take the counter, and in an action to recover the price which was to be paid, the plaintiff offered evidence to show that it was customary in the trade to make walnut counters with such materials. He also offered o prove some understanding with the defendant, outside of the contract, by which it was agreed that the counter was to be made in conformity with the order. In this case (Greenstine vs. Borchard) the Supreme Court of Michigan decided in favor of the defendant, saying that no evidence could be given outside the contract to contradict it, and that no custom could be proved that white wood stained top and door panels to a counter made a walnut counter.

The Art Amateur for December is a number of holiday size and excellence. It contains numerous working designs, fine illustrations of Derby porcelain; practical articles on decoration, needlework, and china-painting; correspondence, literary, and editorial notes. It is impossible to speak too highly of the varied excellence of this superb publication. Price, $4.00 per annum.

☞ Architects, Contractors, Carpenters, and Mechanics generally are respectfully requested to furnish us items of interest for this column. We will gladly answer any and all questions pertaining to the architectural and building interests. If illustrations are necessary to explain your ideas send us a sketch of them and we will make the cuts.

Cut-off Saw for Lathers.

A CROSS-CUT saw is an indispensable tool to the lather for cutting lath in large quantities for short spaces, and for rigging up platforms to work on, and for cutting supplementary studs or strips where such are necessary. The saw should have rather coarse teeth and have plenty of set. Usually the lather thinks that almost any old, used-up saw is good enough for his purpose, and we find him struggling away with all his strength, cutting through a bundle of lath, when, if he had a saw that was worth anything—as a saw—he would perform his labors with about one-half the effort, and in one-third the time. It is all wrong to think of being able to work satisfactorily with inferior or imperfect tools. There is no economy in using tools of this kind, and any lather who fancies he is going to make or save anything by making use of an old buckled, mortar-stained saw, makes a terrible mistake. Get a good saw and keep it in good order, and it will pay you in two weeks.

WHITING is made by reducing pure white chalk to a fine powder. It is mixed with water and size and used for whitening ceilings and inside walls. It will not stand the weather.

MORTAR for the plasterers' use should be well made, and the following rules should be strictly complied with: 1. The lime should be thoroughly slaked, and brought to a paste or putty state. 2. It should remain in the mortar bed until it is perfectly cool, before mixing in the sand and hair. 3. Good mortar can be used with safety eight or ten days after it is made, but in no case should it be used before it is six days old.

[Some authorities say it is best to use mortar for plastering within three or four days after it is first made. They claim that in mortar which stands ten or more days before using, the lime loses a portion of its strength, and the mortar becomes deteriorated thereby. This to a certain extent is true; but, notwithstanding the loss of strength by the lime, and the consequent deterioration of the mortar, every observant plasterer knows that walls coated with mortar made two or three weeks previous to using, stand better than those coated with "green," or freshly-made mortar. Newly-made mortar, immediately applied, frequently causes the walls to chip, crack, and become mottled. Mortar well tempered and as well seasoned works better and cooler than hastily made new mortar, and invariably gives better satisfaction. Colonel Gilmore, quoting from Vicat, and apparently indorsing the statement, says: "It was supposed, for many years, that the longer lime was slacked before it was used the better mortar it would make. Recent experiments prove, however, that this is not the case with a mixture of fat lime and sand only. Better results are obtained with such mortars if the paste be mixed with the sand as soon as the slaked lime has become cold, and care should be taken to use no more water, in the process of extinction, than may be required to produce a thick pulp."—ED.]

The above extracts are from a new work just published, entitled PLASTER; HOW TO MAKE AND HOW TO USE IT. We will send a copy to any address upon receipt of $1.00.

A WRITER says: "The first boring-tool may be assumed to be an awl of some kind. Pliny states that Dedalus invented the gimlet in 1240 B. C. It was destitute of a screw point, but it may have had a hollow pod, and a cross-head forming a handle. Awls are shown in Egyptian tombs of 1706 and 1490 B. C. The screw point was added to the gimlet in course of time, and within our own recollection the twisted shank, which makes it self-discharging. The hint was taken from the auger proper, which may be called a magnified gimlet, now that their specific features have become so closely assimilated in form and function. The auger (*terebra*) was a Greek tool.

From the early descriptions the auger seems to have been considered a shipwright's tool. It formerly had a curved sharpened end, and a concavity to hold the chips; this was a pod auger. To this a lip was subsequently added for some kinds of boring, and in course of time the depression grew into a spiral, which allows the chips to escape while the boring proceeds, instead of withdrawing the tool as the pod becomes filled. The twisted auger is the American invention, and was made by Lil ey, of Mansfield, Conn., about the beginning of the present century, and afterward by Gurley, of the same place.

Augers may be classified as augers, annular augers, taper augers, augers with secondary bores, reamers, or countersinks, or having expansive cutters.

COMMUNICATIONS from all parts of the country are greatly desired, and will be highly appreciated. The fullest information possible will be cheerfully given to all parties seeking the same through this office.

THE MEXICAN CALENDAR OR SOLAR STONE.

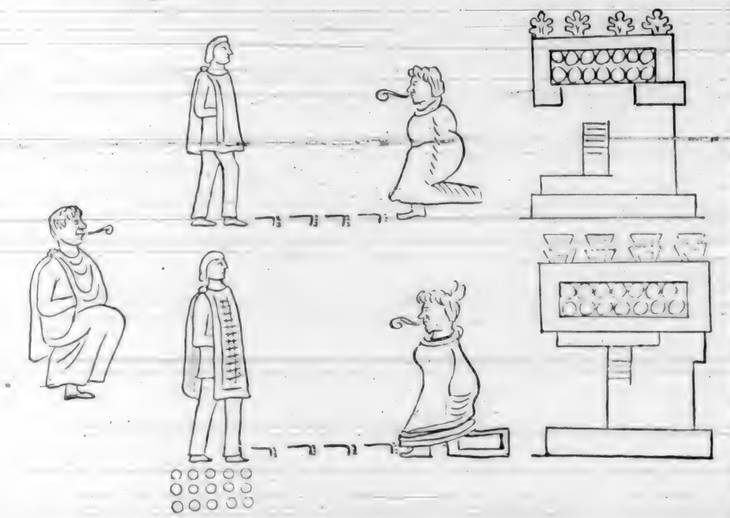
A Lecture Delivered Before the Academy of Sciences and the Geographical Society of the Pacific, on the Nights of the 19th and 27th of November, 1883.

BY EUSEBIUS J. MOLERA.

THE monument bearing the title of this lecture is, on account of the beauty of its design and its size, the greatest and most interesting of Mexican sculptures.

Many Mexican antiquarians have diligently endeavored to solve the mysteries pointed out by the hieroglyphics of this stone, but though a great deal of erudition and research has been shown, the history and meaning of it is yet an unsolved problem.

We shall see to-night that though the theories about the several pictures represented in the stone and their interpretations abound, they are supported only by very controvertible facts. In many instances, starting from a false supposition, the most elaborate conclusions regarding the state of knowledge of the Aztecs are derived. In other cases, after having propounded a pet theory, the facts are twisted by introducing or omitting portions of the hieroglyphics, committing what we might call petty archæological frauds.



The difficulties to decipher Mexican antiquities are, no doubt, very great. In the first place the Mexicans had no phonetic writing, as we use, all their records being kept by picture writing and by tradition. My meaning will be clearer by showing you one of such pictures. The picture here shown is taken from the Vienese collection. We see on the left a man in a stooping position; in the middle two more men standing, and on the right two men stooping. Before the mouths of the stooping men we see a few lines drawn, and under the standing ones fifteen dots or small circles. We also notice on the extreme right of the picture two rectangular figures; the whole of the picture meaning that a man is sending two young men fifteen years old to school, the stooping position indicating the act of bowing or saluting; the lines before the mouth the act of speaking; the lines below, between the middle figures and the left, somewhat similar to footprints, the act of motion, and the rectangular figures on the extreme right the sign *calli* or house, which, with the ornaments, represent school or temple. Finally the fifteen dots under the middle figures represent the age of them.

We can imagine by this sample how difficult it would be to find out *a priori* the meaning of such picture.

The difficulty is increased, inasmuch as though preserving the general characteristics of the delineation of an object, they changed it in all its details. Besides, the same object had different representations, according to the special function that it might perform. We have no truly Mexican chronology; though the history of the Mexican empire scarcely embraces two centuries, we have no fixed dates for any of their events, each writer changing them according to his theories and ideas.

The sources of our information are not authentic, as all the records prior to the conquest were destroyed. The several *codices* made by order of the Spanish Kings and Viceroys, though very valuable and made with all the pains possible, still were made by Indians, who had seen few events of their own history, and had to trust to their information and belief.

The first histories after the conquest were written mostly by priests, who, with their zeal to convert the Indians, exaggerated, no doubt, the atrocities of the aboriginal religion, and by endeavoring to attract the Indians to them exaggerated also the cruelties committed by the military.

It will be conceived, then, that many of the descriptions of the Mexican antiquities are only more or less reasonable theories.

Don Antonio de Leon y Gama, who was an eye-witness when the stone was unearthed, was the first to describe it. He has the merit of having given the first interpretation. He, however, erroneously supposed it to be a calendar, an astronomical instrument, and a sun-dial. Alexander Von Humboldt, Albert Gallatin, Brantz Mayer, and others, have followed Gama. Alfredo Chavero, on a suggestion from Fernando Ramirez, and after him Professor Valentini, have tried to identify this stone with one caused to be built by King Axayacatl. All these authors have made mistakes in their drawings of the stone, and on those mistakes have made most learned dissertations. Gama reverses the position of the sixth figure on the zone of the days of the month. Humboldt, who copied from him, shows a great deal of learning in explaining how this should be the case. Finally, Professor Valentini tells us that the mistake has been made in the tenth instead of the sixth. The zone following the next in Gama has too many elements and the two last zones are also mistaken, as well as in other parts of his drawing.

The writers following Gama have preserved Gama's mistakes and added others of their own.

Our fellow-townsman, Mr. H. H. Bancroft, with a degree of intrepidity worthy of a better cause, in the description of the stone in his "Native Races of the Pacific Coast," makes this bold assertion: "Gama, Gallatin, Humboldt, Dupaix, and *all* others who have copied from them, do not represent the characters on this stone as they really appear. By a photograph taken by M. Charnay, of which the cut on the next page is a copy, it will be seen that all the figures, days as well as parallelograms, are reversed on the representations given by the above-mentioned authors. That is, the engraver, when making his tracings, did *not* reverse the figures before drawing them in the stone, an error corrected in the following cut. Therefore, instead of running from right to left, the days really run from left to right."

This statement is at variance with the facts in every particular; in the first place a simple glance at a photograph shows that Mr. Bancroft's cut is wrong, not only by his figures being reversed from right to left, but the skull, for instance, is upside down; and in other parts is at fault. In fact it is a reproduction of the cuts of the authors he names with the additional mistake of reversing it.

Mr. Chavero reproduces Gama's mistake in reversing the skull.

He thinks that the number of days in the year are to be found on the dots close to the sign acatl around the stone, but, being in need of five dots representing the five nemonteni days, he cleverly introduces them in his picture, four on the right and one on the left of the two heads below, though in the stone there are only two on each side.

Professor Valentini's picture, accompanying his description of the calendar stone, contains also several mistakes. The representation of the sun's face is altogether erroneous. He puts a tentetl, or lip-stone, in the under lip, when in reality it is the protruding tongue as in the two heads below. The tongue itself he embellishes with many dots. In the forehead he introduces the name of the sun god Atonatiuh; he sees braided hair in skeins, where only the coarse hair of the Indians is represented, sunken eyes and lineaments of extreme old age where the lines of the god's mask are represented by the artist.

The sign acatl he transforms in tetlaxoni, besides other minor mistakes.

If we consider that in a single dot or small line many times our authors hang very important parts of their interpretations, it will be apparent the importance of giving, first of all, a faithful copy of the monument to be described, and will strike any one that no greater care has been taken in their representations.

The painting before you is a full size representation of the so-called "Mexican Calendar Stone," made by me from an enlarged photograph one-fourth of the full size, and drawings prepared by me in the city of Mexico from the stone itself. I believe it to be the

only one ever made of that size, and no pains have been spared to make it true in all its details. The original and this copy are eleven feet nine inches in diameter, and the weight of the stone is about twenty-four tons.

I will now proceed to describe the stone, making you acquainted first with that by D. Antonio de Leon y Gama, which is as follows:—

"The Mexican Government, having ordered to level and pave the principal square in Mexico, while digging some of the trenches for the sewers, the stone known as the Mexican Calendar Stone was found very near the surface of the ground, eighty yards to the west of the second door of National Palace and thirty-seven north of the flower market, on the seventeenth day of December, 1790.

Two of the Cathedral Cannons, D. José Uribe and D. Juan Gamboa, commissioners for the building of the cathedral, asked permission to place it in one of the walls of one of the cathedral towers. The permission having been granted by the Viceroy, it was placed in the tower looking west, where it remains to this day.

The principal god worshiped by the Indians was the sun, not only when it shines in its handsomest radiance, but also during eclipses and at night. They represented it in human shape and built splendid temples to it, not only over the famous pyramid at Teotihuacan but in the interior of the principal temple at Mexico, named Quauhxicalco. In Mexico they made many celebrations during the year in its honor, which the King and the nobility attended. The King used to retire for four days into an apartment called Hueyquauhxicalco, or Quauhxicalco, and made penance by fasting and otherwise. During this celebration, which was one of the principal, they sacrificed many captives. This feast was named Netonatiuhqualo, or eclipsed sun, and literally the unfortunate eaten sun (as represented in the picture here shown).

They had many more celebrations, but the biggest was that in honor of its sign Nahui Ollin Tonatiuh, that is the sun in its four motions, accompanied with the via lactea, which they called Citlalinycue or Citlalcueye, which happened in the sixteenth week of thirteen days.

The statue before which the sacrifices were made on the day of Nahui Ollin is the same as the one represented at the center of the stone we are going to describe. It is a monument which contains many of the Mexican epochs, as it points out many of the Mexican celebrations; it was also a pattern which showed the various sun motions in its declination during 260 days of the lunar year, from the equinox to the day that arrived at the Tropic of Cancer and returned to the equinox; that is, the interval spent between the vernal equinox to the autumnal one. It also served as a sundial, by means of which the priests knew the hours they had to perform their ceremonies, by means of sticks or knomons, as we will see later. In this stone it was represented one-half of the yearly solar motion from Aries to Libra, and the diurnal motion from sunrise to sunset.

From what is left of the outer part of the stone, it must have been originally a rectangular parallelopiped. The principal face is square. The wrought part of the stone is not placed at the center of the stone, but a little to the right. The diameter of the circle of the wrought stone is about four yards, and the edge of it nearly coincides with the edge of the stone. It means that there was another stone, which, together with this, represented all the fasts of the Mexican nation.

In the discovery of this stone it is observed the same as it is found in the Roman literature in the six books of Ovide, which contain one-half of the year. The way in which this stone must have been placed is on a horizontal plane, vertically, looking south, with a direction east and west.

The edge of the stone has some ornament without any meaning and about one foot thick, but the figures on the face require an elaborate description, which we are going to give.

At the center of the stone there is seen the sun's picture as represented by the Indian artists. The eight principal beams are the ones represented with the letter R, four of which are over the places which mark the days by fives, and the other four are covered in part by the same divisions. The letter L shows the other eight beams which they also used to ornament the sun's picture, as can be seen in the picture called Tonalamatl. There are also around this circle of divisions little half-circles the same as those over the beams, and they mean the light that surrounds them. To the sun's face join the four squares A, B, C, D, which, together with circles E and F on the sides of the triangle, I on top, and the appendix H at the bottom, form the picture I B E C H D F A, by means of which they represented the sun's motion, and, adding the four numeral characters a, b, c, d, it represents the sign Nahui Ollin Tonatiuh. Inside of each of the four squares is represented one of the signs of the days also marked with the number 4. The one in the square A is the head of a tiger, which, together with the number 4, represents the day Nahui Ocelotle. In the square B is found the hieroglyphic air or wind dedicated to the god Quetsalcohuatl, which was painted at the door or entrance of its temple, and, together with number 4, represents the day Nahui Ehecatl. In the square C is shown with the same number 4 the day Nahui Quiahuitl, with which sign they represented the god Tlalloc, or god of the rain, and finally in the square D is found the hieroglyphic water, which, with the number 4, represents Nahui Atl. It follows that the sun is here represented under the sign and day of the second week of thirteen days of the Tonalamatl, to which corresponds the number 4 and symbol of the solar motion, that is, the day Nahui Ollin, and the signs of the other four squares to the days of the other week of thirteen days in which corresponds the number 4 in the same Tonalamatl, or second calendar. This picture had its origin with the ridiculous fables of the Mexicans about the sun, which they preserved in this picture of Nahui Ollin. According to a manuscript, by D. Fernando Alva Ixtlixuchitl, they believed that the sun had died four times, or that there were four suns which had ended in four ages, and that the fifth sun was the one now shining.

The first sun lasted 676 years, at the end of which, in a year called Acatl, when the sun was at the sign Nahui Ocelotl, men were destroyed from failure of crops, and they were killed and eaten by tigers, which were also finished together with the sun, the destruction lasting thirteen years. The second age ended with the second sun, supposed to be when it was on the sign Nahui Ehecatl, in which, by hurricanes, trees and houses were destroyed, carrying away men, some of whom were converted into monkeys. This destruction happened in the year ce Tecpatl, 364 from the first one on the day Nahui Ehecatl. In another year, named also ce Tecptl, 312 years being elapsed, the third destruction took place, when the sun was at the sign Nahui Quiahuitl, all men were destroyed by fire, and became birds. Finally the fourth destruction happened with the flood, in which all men perished under water, and were converted into fishes. This destruction, they say, was 52 years after the third, in the year called ce Calli, on the day Nahui Atl. The circular figures on either side contain a kind of paws, which refer to the inventors of the Tonatamatl, Cipactonal, and Oxomoco, which were painted in ugly shapes like eagles or owls

The angle I points out the first division of the twenty days of the month which are dedicated to the sun, or the beginning from where they must be counted, as the Indians always counted from right to left, the same as the Hebrews do, and the reverse of our custom.

No. 1 is the first symbol of the year, and is the sign Cipactli, which is represented differently in different calendars, but all agree in a fish with a kind of sword or bone at its nose. No. 2 is Ehecatl. It is the same figure as the one represented in square B, which is named Quebhzalcoatl. No. 3 is a house, Calli, which is also one of the four signs with which they represented the years of the side. No. 4 is a lizard, Cuetzpalin; No. 5 is a snake, Cohuatl; No. 6 is a skull, Miquiztli; No. 7, a head of a deer, Mazatl; No. 8, a rabbit's head, Tochtli, which is also a hieroglyphic of the year; No. 9, water, Atl, which is similar to square D; No. 10, a kind of dog, Itzcuintli; No. 11, a monkey's head, Ozomatli; No. 12, a bended grass, Malinalli; it is the shape of a god of the name Macuilmalinalli; No. 13, a reed, Acatl, which is also one of the signs of the year; No 14 is a tiger's head, Ocelotl, the same as square A; No. 15 is an eagle's head, named Quauhtli; No. 16, another bird's head, named Cozcaquauhtli; No. 17, the motion of the sun, Ollin Tonatiuh, the same as is seen at the center of the circle; No. 18 is Tecpatl or flint, one of the hieroglyphics of the year. No. 19 is Quiahuitl, rain, with the sign they represented Tlalloc, another of their gods, with the same shape as in square C. Finally, No. 20 represents a flower, Xochitl.

There are no numerals inside of these figures, but there are on the circle around them, where can be found 260 corresponding to the twenty weeks of thirteen days of the second calendar or moon's account.

The pointer, which rests on the signs Cipactli and Xoxitl, ends at the outer circle, pointing at the division T, in which there is the symbol Acatl, with thirteen dots, which means that the stone is constructed for the thirteenth year of the fifty-two, but not for the others, as they change on account of losing one day every four years.

The rest of the outer circle represents the milky way, which the Indians called Citlalinycue, a sign which they thought had influence on the sixteenth week of thirteen days of the Tonalamatl, in company with Ollin Tonatiuh, where it is seen similarly represented. The two heads on the lower part of the circle represent the knight of night, named Yohualteuhtli.

I do not know what are the figures around marked with the letter V, though I think they represent clouds. At both sides of the triangle I, are seen two figures marked with K and G. The one with letter G is a flint similar to the one with No. 18, and means the day ce Tecpatl, the beginning of the tenth week of thirteen days of the Tonalamatl, when they had a celebration in honor of the flint, which they called Textecpatl.

The figure M is Ome Ozomatli, or monkey's head. Here follows a very elaborate description of the stone as an astronomical instrument and sun-dial, based on a system of eight sticks or gnomons, which were placed in as many holes placed at equal distances from one another in the stone, around its outer circle. In the stone there are no holes deep enough to support a stick, much less eight of them, and still less equally distant. There has never been found in the ground or elsewhere, or has been any reference made in any author of another stone equal to this, therefore the

astronomical system founded by Gama, which was based on the supposition of the eight gnomons with the two stones, falls to pieces, as well as the glowing accounts of the high attainments of the Indians in practical astronomy.

It is not a calendar; it contains only the circle of the days of the month; but it does not contain the circle of the year nor the circles which they represented as the ones shown herewith.

Señor Alfredo Chavero, perpetual Secretary of the Geographical and Statistical Society in Mexico, is, after Gama, the one who has shown the greatest amount of erudition in describing the Calendar Stone. He has the merit of having proved, on a suggestion from Don Fernando Ramirez (one of the best Mexican antiquarians), the erroneous ideas of Gama and his followers, and that the so-called Calendar Stone was a quauhtxicalli, ded cated to the sun, and upon which war prisoners were slain, and erroneously, in my opinion, supposes to have been wrought under King Axayacatl.

In his Essai on the "Calendario Azteca" he quotes Father Duran, the historian, as follows:—

"The King Axayalacoatl was also busy in working the famous and large stone, very elaborated, where the figures of the months and years, days and weeks, were represented with such detail, worthy to be seen. Such stone many of us saw in the large square near the canal. His grace Alonzo de Montufar, Archbishop of Mexico, ordered the same to be buried on account of the great crimes committed on it, of deaths."

(His. de los Indios de la Nueva España, vol. 1, p. 272.)

Don F. Ramirez appends to this paragraph: "It seems that the stone alluded to is the one called 'Aztec Calendar,' and is now placed in one of the towers of the cathedral."

From the above Mr. Chavero reasons as follows:—

The so-called Calendar Stone is the one now in one of the towers of the cathedral in Mexico. That stone was placed there by order of two canons, as we have seen, being the one found near the canal on the principal square of Mexico on the seventeenth day of December, 1790. According to Duran's description, it is the same stone seen there by himself and others on that spot, and the one caused to be built by King Axayacoatl.

The whole fabric of the argument rests in the assertion of Father Duran that the stone he saw and the one wrought under King Axayacoatl are one and the same.

Mr. Chavero brings forth new quotations in support of his theory, but all from the same author, Duran.

In order to verify the statements of Duran, I have carefully read and compared the statements on the same subject of Sahagun, Clavigero, Critobal del Castillo Torquemada, Ixtlixuchitl, Tezozomoc, and the valuable Codex Ramirez. Though in nearly all these authors the building of the great Cu Teocali, or great temple of Mexico, as well as the stones caused to be elaborated under Kings Moctezuoma the First, and Axayacoatl, are minutely described, yet I have failed in finding the one corresponding with the so-called Mexican Calendar Stone.

In my investigations I have given great weight to the opinions of Mr. Chavero himself, and to those of his associates, Ramirez and Orozcoy Berra. From them I have learned that Duran took substantially all his history from the manuscript "Codice Ramirez." In fact, they say he copied literally in many instances. Chavero says: "I consider this Codex the purest fountain of the history of Mexico, and for that reason I have given it the name of 'Ramirez,' as an acknowledgment of gratitude to the one who preserved it." If the text of Acosta is compared with that of the Codex Ramirez it will be seen that the former copied the latter to the letter. Tezozomoc, though not, strictly speaking, a copyist, followed the same Codex.

These four chronicles, Ramirez, Duran, Acosta, and Tezozomoc, while in reality one and the same, are the only true fountains to write the history of the powerful empire founded by Tenoch and demolished by the last Moctecuzoma (Cronica Mex. by D. H. Alvarado Tezozomoc, precedidada del Codice Ramires, Mexico 1881).

We will now see what these authors say about the stone elaborated under King Axayacoatl.

In the Codes Ramirez fragment No. 1, page 130, the following occurs: "As soon as they arrived in Mexico after the victory, Tlacaellel said to Moctecuzoma to order a stone to the image of the sun, and to name it Quauhxicalli, which means eagle's vase; it was so ordered, so that, at the time of its dedication, the prisoners brought from Cohuaxtlahuacan might be sacrificed. This stone is the one now at the door of the principal church in Mexico, and they say they intend to make a baptismal fount out of it. In this stone the sun is represented in its upper part, and around it the battles that King Moctecuzoma won, viz: Tepeacac, Tochpan, Guaxteca, Cuetlaxtlan, and Cohuayxtlahuacan, all very nicely wrought with other stones, as they had no other instruments."

This stone does not correspond with ours, because though it had the sun's image in its upper part, it was in the shape of a vase, and had the battles above-named wrought around it. Another great stone was elaborated during the reign of Moctecuzoma Second.

Tezozomoc says on the same subject, in page 318, edition quoted above: "Few days after the victory of Cuetlaxtlan and Tochpan, Moctecuzoma decided that, inasmuch as they had so many people from the provinces of Cuetlaxtlan and Tochpan, they might increase and improve the house and temple of Huitzilopochtli, and right there the sacrifice of Huitzilopochtli might take place, by killing the Huestecan prisoners. These after having made the great Cu very high, they built steps to it, and in the middle they put the (tajon) block, where the slaves made in war had to be killed, to commemorate King Chimulpopoca, who had begun it. Cihuacoatl answered, it was well, and the block must not be made of wood, but of stone, with a hole in the middle to put therein the hearts of those who should die on it, after having Huitzilopochtli tasted the blood of them; and that stone should not be built by the Huestecans, but by those of Atzcaputzalco and Cuyuacan, excellent masons, working in the stone the wars of their countries when by you they were subjected to the Mexican Empire. After the stone, or millstone, was finished, they raised it up and placed it in the middle of the large room opposite the principal entrance and of Huitzilopochtli, which was made of stone, and was looking to said stone or wheel, and is the one now in the corner of a house of a son of one of the conquerors, and the sacrificial stone is to-day near the principal church in the city of Mexico." On p 338 we read: "The vase or bowl placed in the great Cu, he called all the vassals, so that they might see the sun's vase, called God Xiuchpilli Cuahhtleehuatl, which we shall try for the first time with the vanquished of Huaxaca." On p. 339: "When the ceremony was ended (the sacrifice of the slaves) one ascended on top of the big house which is the Huitzilopochtli Tlenamalactl, and carried fire in a brasier, and from there a green snake, called Xinheoatli, came down, carried in the arms, and was put in the trough of the hollow stone, called Cuauhxicalli, and there they placed the snake until it was burned and made ashes."

The next time the stones are mentioned is during the King Axayaca. This text is very interesting, as it is the starting point of Prof. Valentine's interpretation of the Aztec Calendar Stone:—

"King Axayaca said to Cihuacoatl a certain day: Father and mauter, I would like very much to repair the round stone which is now used as a brasier and slaughter-trough on top of the house of tetzahuitle Huitzilopochtli, or, if you prefer, to have another made of better workmanship and the one now there may be used in another temple. Cihuacoatl said it was well thought, and immediately caused the neighboring people to be called, viz, those of Atzcaputzalco, Tacuba, Cuyuacan Culhuacan, Cuitlahuac, Chalco, Mizquic, Tezcuco y Huatitlan. About 50,000 Indians gathered together with big ropes and rollers, and went to take a big bowlder at the foot of the great mountain of Cuyuacan. Once brought, they began to work it with flints, strong and sharp, putting the history of the gods, specially Huitzilopochtli; and before they had brought another stone from Ayotzinco, and as they brought it, it fell down on the bridge Xoloco, and never was found again; it may be Huitzilopochtli swallowed it, and thus they brought a bigger one from Cuyuacan. When finished and perfected, Axayaca said to Ilacaleltzin: My father I would like that the stone now on top of the Cu, having been made by my king and mauter Moetecuzoma, be not taken to any other place, but well set, may be placed below the great Cu opposite the house of Huitzilopochtli; and after, said Cihuacoatl: It is also necessary my masters and we, to bring one to build a trough of fine stone that will be used as Cuauhxicalli in the same style, for the blood of the butchered in sacrifice, as it is our present to the honor of our master Huitzilopochtli." P. 409. "They kneeled down before the brasier called Cuauhxicalli."

P. 411. "They came to celebrate the new brasier made Cuauhxicalli of the temple of Huitzilopochtli."

P. 412. "The feast of the butchering of people must be celebrated with great solemnity so that they may see the new temalacatl."

P. 415. "They took them (the prisoners) to the top where Huitzilopochtli was opposite the great temalacatl and the trough called Cuauhxicalli."

P. 416. "They took the heart to the hole of the brasier."

P. 417. "After the guests were gone, Cihuacoatl said: My son you have shown your honor and promise of the temalacatl stone and Cuauhxicalli, stone brasier."

"After finishing the square the walls and pictures of the gods, they hurried the work of the Cuauhxicalli vase, or stone brasier, and in it there was the picture of the sun. Afterward they called the Mexicans, and neighbors, and they raised the great stone or brasier to the top, though the temple was 160 estados high."

P. 516. Speaking of the sacrifice. "They took the hearts of the prisoners and put them into the hole of the stone, called Cuauhxicalli, which had a hole a yard around. This stone is now opposite the principal church" in Mexico.

From what we have read we see that the stones mentioned are:—

1. *Techatl*, which was a block (tajon); it was the common sacrificial stone.

2. *Temalactl*. This was the stone used in the gladiator's sacrifice. It is like a millstone in shape, and had a hole in the middle where the prisoner was tight.

3. *Cuauhxicalli*, from *cuauhtli*, eagle and

xicalli vase, cup. This is the one described so many times; had the sun's image on the top. It had a hollow vase or cup in the middle to receive the blood of the prisoner.

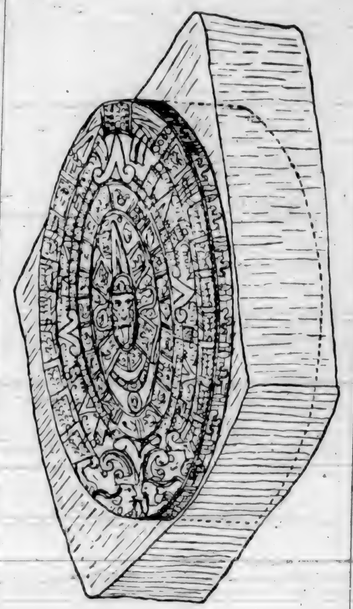
There was another kind of stone like this called:—

Teocuauhxicalli, from Teo, god, and cuauhxicalli. This, according to many authorities, was painted. There is one such stone buried yet in the plaza of the city of Mexico, a description of which was published by Brantz Mayer. Our stone does not correspond to any of the above, nor to any built during the reign of Axayaca, as supposed by Mr. Chavero. He says that our stone is a true cuauhxicalli, but it cannot be, as we have seen that cuauhxicalli are cylindrical in shape, and have a hollow in the middle to receive the blood, and our stone has none. The etymologic of the word says so: *Cuauhtli*, eagle; *xicalli*, vase, cup.

The only text supporting Chavero's theory is Duran, but Chavero himself says that Duran copied from the anonymous author of the "Codex Ramires," and we have seen that this author, as well as Tezozomoc, does not support Duran's statement. On the other hand, Duran's mistake is easily accounted for. He had read on the anonymous manuscript the description of the Cuauhxicalli, where the sun's picture was represented, and having seen in the stone called the Calendar also the sun represented, naturally enough thought it to be the same. But many other stones have been found with the sun represented in them, and as they correspond in other respects to the ones described to have been built during Axayacoatl, we may safely suppose that the one here painted is not Axayacoatl's Cuaxicalli, as supposed by Mr. Chavero. Thisantiquarian has written a very long and elaborated description, showing a degree of erudition hardly equaled by any other exponent of this remarkable monument, but all are theories, supported by few facts.

Prof. Philipe J. J. Valentini, Ph. D., following the ideas of Chavero, has also made a description of this stone. He misquotes Tezozomoc, and from the doctored text of that writer he builds his theory, which is no other than Chavero's. Some of the mistakes he makes in his drawing of the stone we have already shown. I will not detain you with his description, as he does not bring any important facts.

My idea about the so-called Calendar Stone is that it is an *unfinished* stone, similar to the one called the Sacrificial Stone. If you cast your eyes to the two perspective drawings here before you, you will see at a glance the similarity, the only difference being the size and ornamentation. Another reason in support of my theory is that, were not this the case, they most surely would not have carried four times as much stone as they needed, especially when we read of the great trouble in carrying them, which we may easily believe, from the mechanical means at their disposal. Then they intended to use all the stone they carried, and as they used only about nine inches, and it is nearly thirty-six inches thick in my opinion the stone, as intended, was as marked in dotted lines in the perspective drawing.



It may be said that in the sacrificial stone there is an excavation, but about that I will remark that, in the opinion of many, that hollow was made by Vandals, and not Indians; and, supposing it was made by the Indians, we can see it was not made until the stone was finished, and most probably not by the artist, as we see the lines crooked and cut in the figures in a very unsymmetrical way. Then, as our stone was not finished yet, of course they had not made the hollow and gutter. In the histories we find passages in support of my theory, though I don't wish to be understood that I intend to determine the time in which it was built. I will quote them to show that such a stone like the one we speak was built, or, rather, intended to be built, at the time of the last Moctecuzoma and was never finished.

The already-named anonymous author of the "Codex Ramirez" says, p. 77:—

"They say that Moctecuzoma being astonished with the many signs and wonders against his kingdom, decided to bring a very great stone to make sacrifice on it, to pacify the gods. Many people went to get it but it was impossible to move it, breaking all the ropes, etc." Here follows how the stone talked. And when they arrived to the channel at the entrance of this city, it fell down and was lost.

Tezozomoc says on the same subject, p. 662: "Moctecuzoma remembered that in his time he had not made any work to perpetuate his memory. He called Cihuacoatl that he might order to be made for the temple Huitzilopochtli a stone larger two (codos) and higher than that already there. Cihuacoatl called all the masons and stone cutters of the wards of Teopan, Movotlan, Atzacvatco and Cuepopan. He told them that the King ordered them to make a stone like the one on top of the Cu of Huitzilopochtli with the only difference that it should be made larger and taller, and all of you together must go to get it."

P. 665. "When they arrived to the great bridge of Xoloco and in the middle of the bridge, the stone said, 'here and no further,' and after that the bridge broke and many were killed."

Clavigero says, p. 231, London edition, 1787: "In 1509 the war against Xochitepec happened, that State having rebelled. In the year following, Montecuzoma, thinking the altar for the sacrifices too small, and unproportioned to the magnificence of the temple, caused a proper stone of excessive size to be polished and cut, and commanded it to be brought in due form to Mexico. A vast number of people went to drag it along, but in passing a wooden bridge at the entrance of the city it fell, drawing four men, amongst them the priest. The king and the people were a good deal disconcerted, but without giving up the undertaking, they drew the stone with prodigious labor and fatigue out of the water, and brought it to the temple, where it was consecrated with the sacrifice of all the prisoners that had been reserved for this great festival, which was one of the most solemn ever celebrated by the Mexicans."

Another argument has been brought to show that the stone was built under King Axayacatl's reign, and that is the hieroglyphic thirteen acatl on top of the stone corresponding to the year 1479, which, according to some authors, Axayacatl lived; but there are as many authors who state that King Axayacatl was dead and King Tizoczic, who ordered the Cu or great temple to be enlarged and a larger stone to be wrought, died before his projects were accomplished. Then this stone might be one of the unfinished stones of King Tizoczic.

But we have another date written on the sun-face, viz: 2. Acatl, and this date corresponds to the year 1507, which would correspond near enough considering the confused Mexican chronology, to the year in which Montecuzoma the Second ordered the great stone to be wrought. The other date, 13 acatl, would then be the thirteenth day of their first month, Atlacahualco, corresponding to our 10th of March, in which they celebrated the sacrifice of the fattened prisoners.

We see from this that two unfinished stones exist, according to the Mexican chronicles; that under Montecuzoma the Second the largest ever wrought was ordered to be in shape the same as the one on top of the Cu. Ours is the same in shape, excepting that it is not finished, and it is larger, and corresponds therefore to the one ordered by King Montecuzoma the Second.

I have endeavored to give, in a short space of time, a clear idea of the principal theories and interpretations of this monument. I have no doubt that many things have not been presented with the fullness that could have been, and for that I offer as an apology the difficulty of the subject and the limitations of a lecture.

San Francisco, November 19, 1883.

Some materialistic scientists are very fond of quoting the remark of Kant: "Give me matter, and I will explain the formation of a world;" but they omit his other words, "Give me matter only, and I cannot explain the formation of a caterpillar."

Wall supports for clothing: When you drive a nail into a wall, clothes-press, or closet, to hang things on, drive it through a spool up to the head. Select a spool with a hole large enough so that the nail will not split it.

Cracks in Buildings.

The numerous cracks that disfigure that part of plasterers' work which is lathed arise partially, as has been hinted, from the settlement, shrinkage, or contortion of the floor, partition, battening, or cradling, to which the laths are nailed; but sometimes split or damaged laths are used, and at others weak and crooked ones of unequal thickness, that ought to be rejected, are worked in with the rest, and these split and break when nailed overhead where the lathing carries the whole weight of the plaster. In many cases also the laths are much split in the process of lathing, and are often nailed too close together to allow the stuff to insinuate itself and curl behind the laths to form a good clench or key, which is one safeguard against cracked ceilings. Among several causes which contribute towards the impaired appearance of the tops of so many rooms may be mentioned joisting laid at too wide intervals, whereby the laths sag under their burden, and also the folly of fixing and lathing ceiling joists in double or framed floors before the other timbers have settled down and taken their bearings. Then, perhaps, when these dangers have been averted, a quartered partition, that has been wrongly allowed to rest upon the floor, begins to make its weight felt; or, it is found that, after the pricking up coat has been laid, the brandering or counterlathing has been forgotten. In common ceilings sometimes the filling in pieces under the trimmer-arch are too far apart, and often enough the floor is not sufficiently rigid or stiff, even when strutted and tightened with a tension rod, on account of the shrinkage of the joists, to preserve the ceiling formed on its under side from drooping out of the horizontal and cracking, nor from deflecting still more, and shaking and sounding almost like a drum when trampled upon; but of course, notwithstanding what has been said, there are instances of good and substantial floors settling a little without injury to equally good ceilings beneath them. Sometimes cracks owe their commencement to the absence of any key immediately under the joists, where the plaster could not be squeezed through to obtain a hold in consequence of the laths being nailed with too much overlap, it being preferable, nevertheless, to avoid overlaping altogether. There are, however, other conditions depending upon the quality of the plaster itself that have to be satisfied before a ceiling is to be exempt from cracking. The coarse stuff may be partly composed of mold that will cause it to shrink and crack, and the hair may be either deficient in quantity, too short, imperfectly beaten, and worked into the stuff, or it may be dirty or rotten. Even if the sand and hair be both of proper quality, the leak may not have been allowed sufficient time to slime thoroughly before the plaster was required, for workmen cannot be kept waiting, and the consequence is blistering, cracking, and the partial disintegration of the work by the lime blowing. Supposing, however, that the mixture is all that could be desired, that it is evenly spread, hangs together well, is properly scratched or keyed for the floated coat, which also is laid on satisfactorily, there remains the common danger of cracking the ceiling permanently by prematurely applying the setting coat, for unless the other coats are quite dry there will be unequal shrinkage, which must entail cracking. Where cement is used for internal work it is necessary to add a sufficiency of sand to prevent cracking, and to prevent the layers from splitting away from each other it is best to apply it in one coat of equal thickness, taking care to well hand-float the setting coat of neat cement over it before it is too dry, else the face will crack and peel off. Plaster of Paris when mixed with common plaster to make it set more rapidly requires much dexterity in its manipulation to prevent cracks appearing. It would be needless to point to the numerous cracks that are always to be observed somewhere or other about buildings that are externally wrapped up in cement or stucco, particularly near the cornice, parapet and blocking course, or where due care has not been observed in preventing the formation of fissures, in which water has lodged and produced havoc by freezing; and without occupying time by further allusion to the means by which cracking may be avoided in other branches of plasterers' work, it will be an appropriate conclusion to point to the necessity of employing screws with no parsimonious hand in securing enrichments, center-pieces, decorated cornices, and the like heavy kinds of ornamentation, which are sometimes placed profusely overhead, so that there may be as little chance as possible of the cracking proving dangerous as well as unsightly. It is true that the plasterer is hedged in with many troubles to insure a good ceiling, for after having escaped all the dangers briefly adverted to, the joiner by fixing a cupboard front on the chamber floor may crack the coving of the drawing-room cornice, or the gas-fitter in lifting a board to put in a syphon to the gasalier may similarly mar the beauty of the center flower, but this should only open his eyes to the necessity of erring on the side of coherence and strength. It is fortunate, indeed, that so few people are annually injured by falling ceilings, considering how many are cracked and to all appearance ready to fall, as well as the weight of plaster and the momentum it acquires in its descent. In many ill-built houses where the laths are crooked, the plaster, in order to get the ceiling tolerably level, is in some places more than an inch thick, and supposing that a small lump, about three feet super in extent, and which would weigh about twenty-five pounds, were to become detached, it would fall upon a person's head sitting underneath at a vertical distance of only five feet from the hole left in the ceiling with a force which would amount to no less than about 450 pounds.

Before a structure is fit for occupation there are yet other cracks contributed by the bell-hanger, gasfitter, paperhanger, painter, glazier, etc., that would make their appearance. As the nature of many of these will probably occur to the reader, and a detailed account perhaps weary by monotony, it will be sufficient to add that it is as mortifying to the grainer to see his *chef d' ouvre* disfigured by the door panel splitting as it is to the painter to notice the blisters arising from the body of paint he left on the eaves' corbels of unseasoned timber, to become cracked and knocked off in fixing the spouting. The paperhanger observes also that the cracks in the plastering carry his own work with them, and thus it appears that the ramification of responsibility among the trades already noticeable, as between the bricklayer and carpenter, carpenter and plasterer, etc., becomes at last intricate enough to render it exceedingly difficult to lay the fault of any crack at the right door, or, in other words, to establish with anything like certainty the cause of cracks in buildings.—*Building Times.*

Are Apprentices Free When They Are One-and-Twenty?—One of the articles of faith shared alike by generations of masters and apprentices has been that the latter, notwithstanding the length of the term they are bound by their parents or guardians, are legally free the moment they attain their majority. While there are doubtless masters who will be gleeful, there must be a still larger number of apprentices to whom the recent decision in the case of Richardson, Koolman, and Iager, *vs.* Harrison, will be a dreadful blow. As soon as he attained his majority, Master or Mr. Harrison, an apprentice to this well-known firm of electrotypers, chose to absent himself for a time, and on being called to account by his masters, pleaded that being of age, it in itself canceled his indentures. In happy language he further declared that "this trade does not satisfy the appetite of my desire." His masters sued the father for the sum of £120, being the estimated loss of the services of the son until the expiration of the indentures, and what is more, they got it. An application made on behalf of the defendant for a new trial was refused—with costs—by the assistant judge. The decision will affect tens of thousands of apprentices not only in this but in every other handicraft.—*London Printing Trades Journal.*

Chinese Composition.—The Chinese compositor has a merry time while working. One would imagine he was on a six-day go-as-you-please walking match instead of setting type. He cannot sit at the case as our printers do, but must constantly travel from one case to another, as the characters needed are so numerous and they cover so much space that it is impossible to keep them in anything like the room required for the ordinary case. In setting up a piece of copy, the Chinese printer will waltz up and down the room for a few moments, and then go down stairs for a line of lower case. Then he takes the elevator and goes up into the third story after some caps, and then out on the wood-shed after some astonishers. Intelligence in his case is not so much a requisite as being a good pedestrian.

India Ink.

A CHINAMAN named Chen-ki-souen has written a monograph on the famous Chinese ink, more commonly known here as India ink. We find the following interesting extracts, regarding its history and preparation, in the *Deutsche Industrie Zeitung*.

Many articles are found in the extensive literature of China written by their learned men about the paper, ink, and brushes that they use for writing, but unfortunately very little is said about the technology of their inks. It is quite otherwise in the recent book written by Chen-ki-souen, for he describes every stage of its preparation with great accuracy and in detail.

According to our Celestial author, a kind of pigment ink was discovered 2697 to 2597 B. C. It was employed for writing on silk with a bamboo rod. Afterward an ink was prepared from a certain stone (*encre de pierre*), which is still known in China as che-hei. It was not until 260 or 220 B. C. that they began to make an ink from soot or lampblack. The soot was obtained by burning gum lac and pine wood. This ink was made first in round balls and very soon supplanted the stone ink.

For a while the province of Kiang-si appears to have had a monopoly of ink making. Under the dynasty of Tang, in 618 to 905 A. D., there was a special office called an inspector, who had charge of its manufacture. He had to furnish the Chinese court with a certain quantity of this ink annually. Some of the factories seem to have been "royal Chinese" factories. The Emperor Hinan-Tsong (713 to 756 A. D.) founded two universities, to which he sent 336 balls of ink four times a year.

The most celebrated ink factory in China is that of Liting-kouei, who lived in the latter part of the reign of Tang, and is said to have made an excellent article. He made his ink in the shape of a sword or staff, or in round cakes. The test of its authenticity consisted in breaking up the rod and putting the pieces in water; if it remained intact at the end of a month, it was genuine Li-ting-kouei. Since the death of this celebrated man there seems to have been no perceptible advance made in the manufacture of India ink.

In the manufacture of lampblack nearly everything is used that will burn. Besides pine wood we may mention petroleum, oils obtained from different plants, perfumed rice flour, bark of the pomegranate tree, rhinoceros horn, pearls, musk, etc. Nor does fraud seem to have been entirely wanting. According to Chinese authorities, the principal thing is the proper preparation of the lampblack; the best smells like musk, and the addition of musk not only serves to give poor goods the resemblance of fine ones, but really makes it worse.

The binding agent plays the chief part next to the lampblack; ordinary glue and isinglass alone are now used. In old times glue made from the horns of the rhinoceros and of deer was employed.

Good Chinese ink improves with age, and should not be used for a few years after it is made. It is not easy to keep it as it must be protected from moisture. Some persons, in rubbing it up, make circular movements that soon ruin it. It is better to rub it in straight lines back and forth with the least possible pressure.

How Stumps Are Blasted Out.

A CORRESPONDENT of the *Ohio Farmer* gives his experience and some practical directions on this subject, as follows:—

"Last spring I sent to Indiana and hired a man to come and blast our stumps. I paid 42½ cents per pound for the powder, and 15 cents for each stump taken out—he to furnish caps and fuse. The stumps were mostly white and burr oak, from twenty to forty inches in diameter, and had been cut from six to twelve years. Sixty-seven of the worst were taken out at an expense of 68 cents per stump. There were only three or four failures in the whole lot. As they were blown into pieces, it was much less work to pile and burn them than when taken out in the ordinary way.

"I bought material and took out nearly 200 smaller stumps at an expense of about 20 cents each. It took me about ten or fifteen minutes to prepare a blast. I used a two-inch auger on a five-foot shaft for boring under the stump. A crow bar will do in soft ground; those who follow the business use a two and a half inch auger. The charge should be put as nearly under the center of the stump as possible.

"It is not very dangerous to use, as fire will not explode it. The cap is placed in the cartridge, and is connected by a fuse. You light the fuse, which in one or two minutes explodes the cap. The concussion of the cap, which is equal to 500 pounds, explodes the dynamite or Hercules powder. Eight or ten rods is a safe distance if you are facing the stump, or you can easily dodge chunks if any come toward you.

"It will not pay to use it very extensively on green stumps, as it will take from three to eight pounds per stump, and will not give very good satisfaction at that."

The Oil Stone and Its Uses.

TWENTY years ago the oil stone was found only on the joiner's bench, and possibly on that of the machinist, and its sole use was the sharpening of the edges of tools. To-day its use has extended beyond this province of edging tools to that of grinding, reducing, finishing; in fact, invading the limits of the grindstone, emery, rottenstone, tripoli, and reaching almost to rouge. This stone, which is a slate known in science as novaculite—from *novacula*, a razor—is cut and dressed in hundreds of varying forms for differing purposes. In any hardware or mechanic furnishing store it may be found in all manner of shapes under the name of "slips" adapted for sharpening tools of all forms. In dentists' supply stores it may be seen in twenty or more cylindrical and circular forms, and so minute as to be used at a rapid rate of revolution even between the teeth of dental-suffering humanity. Some of these cylinders, ovoids, cones, and edged wheels, are so minute that a pea looks large by their side; yet they are all veritable grindstones.

In the manufacture and finishing of the metals, the oil stone, or novaculite, plays an important part. Our recent exaction as to fits and measures can hardly be filled except by the use of this stone, and it is in demand for truing turned surfaces and planed areas of iron and brass, slowly grinding down the imperfections left by the finish file and the corundum wheel. Recently its powder has largely usurped the place in mechanics' valuation of flour of emery or emery of the higher grades. It is found that a finish "for fit" can be readily obtained by its use in much less time than that by the scraper; and that it does not leave embedded particles of quartz or corundum to keep up a perpetual wear. This material is not strictly an *oil* stone; it can be used with any vehicle, water, benzine, or kerosene oil; it is amenable to all of these. Perhaps its best use is with water, especially when the stone is of the harder sorts, as the Ouachita.—*Scientific American.*

Bent Wood.

A PIECE of timber that has been steamed, whether it is bent or not, has its stiffness increased. It is more brittle than it was before, and for some uses it will not do as well; and yet there is a quality of timber that the steaming process and the kiln-drying process affect very much the same; they both cook the gum in the timber and make it brittle and stiff. There is a grade or class of hickory that is benefited by being steamed or kiln-dried for use as spokes or whiffletrees. There is a kind of hickory that never becomes stiff by a natural process of drying, and one of the desirable qualities of a spoke, rim, or whiffletree is stiffness as well as strength: you take that hickory, and it is the very best we have, and steam it, and it is better suited for these purposes than it was before. It is difficult to tear apart a piece of bent wood; the fibers are interwoven one with the other, and when we come to split the stock open we find that its character is entirely changed.—*The Lumber World.*

IT is a matter of surprise to many that places and sections of country which are entirely unfit for agricultural purposes, are not utilized for tree culture. The black walnut for instance produces a butt fourteen inches in diameter in as many years; it requires no particular attention, makes an elegant tree and offers a desirable shade. No tree valuable for its timber in cabinet uses, will attain anything like the above dimensions in the same length of time; the only exception to this is the black birch.

Plasterer's Manual, enlarged. Price 75c.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in DEWEY & Co's SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.]

FOR WEEK ENDING NOVEMBER 27, 1883.

289,060.—KEY SEAT CUTTING MACHINE—Geo. W. Bonds, S. F.

289,064.—EXTRACTING PRECIOUS METALS BY LEAD BATHS—Brown & Gates, S. F.

289,217.—GAME TABLE—George Calder, Mill Creek, U. T.

289,079.—PUMP—C. L. Fonts, S. F.

289,245.—DRAWER PULL—F. Frank, Suisun, Cal.

289,094.—SHINGLE SAWING MACHINE—O. C. Hanson, Eureka, Cal.

289,105.—BUILDING FRONT—P. H. Jackson, S. F.

289,107.—SEWER GATE—Samuel Johnson, S. F.

289,108.—SEWER GATE—Samuel Johnson, S. F.

289,268.—ANIMAL TRAP—George W. Jolly, Paraiso, Cal.

289,010.—CELL CASE FOR EGGS—Jos. Lyman, San Jose, Cal.

289,114.—TIRE TIGHTENER—H. B. May, Oregon City, O. n.

289,118.—HARROW, ROLLER, ETC.—J. D. McKinnon, Portland, Ogn.

289,295.—LAYING PAVEMENT—Wm. M. McLane, Los Angeles, Cal.

289,127.—CULTIVATOR—R. K. Nichols, Lower Lake, Cal.

289,128.—CAR BRAKE—Jas. O'Donnell, S. F.

289,134.—DIRT SCRAPER—Jas. Porteous, Fresno, Cal.

289,149.—METALLIC FENCE POST—D. B. Scott, Shingle Springs, Cal.

289,159.—ASH HOIST—John D. Spreckels, S. F.

289,040.—RAILWAY AND CATTLE WATER SUPPLY—C. B. Sykes, Calabasas, A. T.

289,194.—WATER HEATER—J. B. Webster, Los Angeles, Cal.

14,438.—DESIGN FOR BRACELET—R. H. Ahn, S. F.

14,442.—DESIGN FOR WIRE FENCE—G. Hunziker, Cloverdale, Cal.

14,444.—DESIGN FOR CAKE SOAP—Anthony Lucy, S. F.

3,713.—LABEL—N. W. Griswold, Alameda, Cal.

NOTE—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

BUILDING SUPERINTENDENCE.

A Manual for Young Architects, Students, and others interested in Building Operations as carried on at the present day. Price $4.00.

Should this Journal be received by any subscriber who does not want it or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. We will not knowingly send the paper to any one who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, we shall positively demand payment for the time it is sent.

Masons and Builders' Exchange of San Francisco, Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

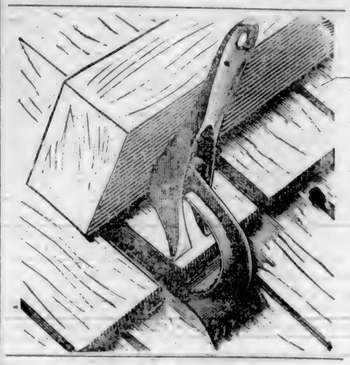
KENNETT'S PATENT ROOF BRACKET.



NO MORE

Leaky Roofs.

Saves Time, Material, and Money.

Simple, Reliable, Durable, and Cheap.

THE BEST IN THE WORLD.

This Bracket is used to instantly secure a Scaffold or Staging on a Shingle roof.

Without the Use of Nails or Screws.

It is made of best **Malleable Iron**, and cannot be broken.

The above Illustration shows the Bracket partly under a shingle and a scantling, in position. By this construction it forms a clamp, and the more pressure there is against it the tighter it gets. The bracket is placed over a joint, so that it holds on to three shingles and makes it doubly secure, and obviates any possibility of slipping or of splitting shingles.

The scantling lies close to the roof, so that loose nails and shingles cannot pass down and off the roof. It engages with thick or thin shingles with the same readiness and security.

It is the

Safest Mode

IN THE WORLD

OF FASTENING A SCAFFOLD.

It Cannot Slip or Give Way.

For Shingling, Repairing, or Painting a Shingle Roof, or in case of a fire to go on a roof it has no equal. It requires but a few secon ds to change from one place to another, requires no nails, splits no shingles in taking up your scaffold, as in the old way, and thereby

Saves Time, Labor, and Money,

—AND MAKES A—

Stronger and Safer Scaffold.

We Have Been Appointed

Sole Agents for the Pacific Coast FOR THIS BRACKET.

Price, $4.00 per Dozen.

In order that every mechanic on the coast may possess these Brackets, we will send a pair, post-paid, to any address, upon receipt of **75 cents.** ADDRESS

$40,000.

Oak and Buchanan. Two-story frame stable.
O.—W. T. Wenzell.
A.—Schmidt & Havens.
C.—T. Maxwell.
$2,500.

Birch Av., Larkin and Polk.—Five two-story frames.
O.—Mrs. A. Skae.
A.—Schmidt & Havens.
C.—R. Smilie.
$16.000.

Fifteenth, x Noe and Sanchez. Two-story frame.
O.—Chas. Schmidt
A.—Schmidt & Havens.
C.—T. Maxwell.
$4,000.

Twenty-ninth, near Harrison. Two-story frame.
O.—J. Whelan
C.—F. Hogan.
$1,800.

Mission, nr. Fourth. Four-story and basement brick.
O.—H. D. Hanks.
A.—Percy & Hamilton.
C.—J. C. Gibson.
$35,000.

Thirteenth, near Harrison. Additions.
O. and B.—J. S. Wieland.
$1,500.

Folsom, near Sixteenth. Additions.
O.—Enterprise Brewery.
C.—W. F. Hewe.
$3,500.

Channel, nr. Seventeenth. One-story frame.
O.—J. B. Williams.
C.—W. Wickersham.
$2,500.

Dolores, nr. Twenty-ninth. One-story frame.
O.—L. Spott.
C.—Grace & Loftus.
$850.

SAN JOSE.

Stockton Avenue. Two-story frame.
O.—A. B. Miner.
A.—L. Goodrich.
C.—W. S. Boyles.
$6,000.

Third, near St. John. Two-story frame.
O.—F. J. Lacoste.
A.—L. Goodrich.
C.—M. D. Green.
$6,000.

Berryessa. Two-story frame.
O.—School District.
A.—L. Goodrich.
C.—J. S. Selby.
$4,500.

San Pedro, near Market. One-story frame.
O.—J. N. Cora.
A.—A. Vincent.
C.—S. J. Mill Co.
$1,200.

Market, near Santa Clara. Two-story brick.
O.—G. Raggio.
A.—A. Vincent.
C.—S. J. Mill Co.
$3,500.

Julian Avenue. One-story frame.
O.—C. Hellison.
C.—J. Lenzen.
$2,000.

Market, near Santa Clara. Two story brick.
O.—J. S. Lynden.
A.—A. Vincent.
C.—C. Drew.
$2,800.

Vine. One-story frame.
O.—Karl Klein.
C.—J. Lenzen.
$1,700.

Fourth. One-story frame.
O.—M. Glubetuch.
C.—J. Lenzen.
$3,500.

Delmas Avenue. One-story frame.
O.—Van de Castelle.
C.—J. Lenzen.
$3,200.

Stockton Avenue. Two-story frame.
O.—E. C. Singletary.
C.—J. Lenzen.
$18,000.

Market, cor. Bassett. Two-story frame.
O.—Mrs. Morrison.
C.—J. Lenzen.
$6,500.

OAKLAND.

Filbert, near Eighteenth. One-story frame.
O.—R. Murphy.
A.—C. F. Man.
C.—Parrish & Hughes.
$2,200.

Eighteenth, near Grove. One-story frame.
O. and B.—E. Clark.
$1,800.

Telegraph Avenue, nr. Seventeenth. Four one-story frames.
O.—W. Collins.
A.—C. F. Man.
C.—Borden & Milwain.
$6,400.

Linden, corner Sixteenth. Two-story and basement frame.
O.— —Campbell.
C.—J. E. Hanna.
$5,500.

Myrtle. near First. One-story frame.
O.—Mitchell & Co.
$1,600.

Pine, corner Taylor. Four one-story frames.
O. and B.—P. Svenson.
$5,500.

Tenth, cor. Kirkham. Alterations.
O.—J. N. Harris.
$1,000.

Chestnut, nr. Fourteenth. One-story frame.
O.—G. T. Leone.
C.—M. R. Turner.
$1,800.

Twelfth, corner Chestnut. Two one-story frames.
O.—Mr. Crocker.
C.—M. R. Turner.
$3,600.

Seventh, near Chestnut. Two-story frame.
O.—P. Gibbons.
C.—J. Coveney.
$2,000.

Second, near Castro. One-story frame.
O.—J. P. Mill Co.
$1,000.

MISCELLANEOUS.

Alameda. Encinal Avenue, near Chestnut. One-story frame; O. and B., H. C. Brown; $1,600.

Woodland One-story frame; O., J. D. Lauson; C., Wm. Carson; $2,500. One-story frame. O., H. P. Eakle; $1,500.

Cacheville. Two-story frame; O., Geo. Greene; C., G. K. Glenn; $2,500.

Fresno. Two-story frame; O., C. Hutchinson; A., H. T. Bestor; $3,000.

Brooklyn. Highland Park; two-story frame; O., W. J. Stuart; A., W. G. Copeland; C., — Brown; $3.000.

Petaluma. Two-story frame; O., Rodd & Kiel; A., T. J. Welsh; C., J. F. Cleary. $4,500.

Mission San Jose. Additions to Church; A., T. J. Welsh; C., — Binet; $2,900.

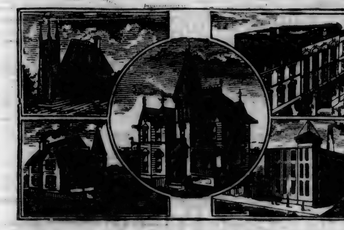
The California Architect and Building News.

VOLUME V. NUMBER 1. | SAN FRANCISCO, JANUARY, 1884. | $2.00 per Annum, in Advance. Single Copies, 20 Cents.

THE

California Architect



AND

BUILDING NEWS

Published on the 15th of each month

BY THE

San Francisco Architectural Publishing Co.

JAMES E. WOLFE, GEO. H. WOLFE,
EDITORS AND MANAGERS.

Rooms 11, 12, 13, No. 240 Montgomery Street.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.

Back Cover, outside, each insertion, $2.00 per square.

Page preceding reading matter, $1.75 per square.

Page following reading matter, $1.50 per square.

Inside Pages, each insertion, $1.00 per square.

Full Page, inside, one insertion, $40.00.

Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

Our Fifth Volume.

WITH this issue we present the first number of Volume 5 of this journal. We are well pleased with the encouragement received during the year, and that the general public may know the extent of the good-will manifested towards us by those interested in the different branches of the building interests, we will say that, during the year just closed, we have added to our subscription list

EIGHT HUNDRED AND NINETY-THREE

new subscribers.

The mammoth supplement issued last September had much to do with this large increase. We distributed

FIFTY-TWO THOUSAND

Of that issue, and are more than pleased with the result. Such was the favor with which it was received, and the encouragement offered so large that we will, in the near future, print supplement No. 3, and will positively guarantee an issue of

ONE HUNDRED THOUSAND COPIES.

Eastern advertisers will do well to inquire of us in regard to space, as our past experience has proved that it is but little trouble to fill up all the room we can spare for advertisements, because those favoring us feel assured that the number of copies are printed that we promise.

Our Competition.

WE are well pleased at receiving so many letters from architects all over the country inquiring in regard to the COMPETITION announced in our last and present issue. For the benefit of many inquirers, we would say that it is not confined to the architects of this coast, but is open to all. The professional standing of the gentlemen composing the committee on the awarding of premiums is such that there can be no question upon the result of their decision being strictly just to the various competitors.

Every architect in the State should insert his professional card in our columns, and thereby prove that he is endeavoring to assist in building up an architectural journal that will take rank with any printed. The charge is small. We want the influence your names will give, and we promise to spare no efforts in making the "California Architect" fully represent the views of a majority of the Profession on this Coast.

ROYAL INSTITUTE OF BRITISH ARCHITECTS LIBRARY

Business Prosperities.

BUT few if any year in the history of California as a State, has closed more satisfactorily, in a comprehensive sense, to the people of the State, than 1883; and seldom, if ever, have the prospects for the year to come presented brighter and more cheering indications for the future. In all directions, in all lines of trade and commerce, in all mechanical, manufacturing, and labor spheres and circles, there has been a large degree of substantial successes; and the dawn of 1884, and the indications for the year are full of encouragement that the current twelve months will yield their full quota of good things to all classes.

While there have been a few individual failures and non-successes in business, there are but very few of the entire inhabitants of the Pacific Coast who are not able at the present time to make a better financial showing than they could one year ago. Nor is this general prosperity confined to any particular class of individuals, but reaches, in respective degree, from the millionaires down through all gradations of business pursuits to the humblest toiler for daily bread. The thrifty and economical mechanics and workers, who, a few years ago, found it difficult to make all ends meet, have, during the past and preceding year, been able to secure comforts, and make considerable advance in the direction of better circumstances, and scarcity against the various adversities to health and fortune, which are possible to come to any one at any moment without warning. There is no better nor more reliable criterion for judgment as to a general state of prosperity among the people of any city or State than that furnished by the building activities. When architects are busy, building contractors full of work, prices of material high, the working forces of skilled and unskilled labor fully employed, it is safe to assert that "times are good" and "everybody doing well." This has been, and is now, the state of the case in California, and it is safe to urge the assertion as a fact, in prospect, that there will be a greater amount of money expended in building operations during the current year than there has been within the twelve months of either of the preceding ten years. The demand for moderate cost tenements, houses, and flats continues, and it matters not what additional number may be erected this year, they are likely to find ready tenants. There is but slight probability that building will be overdone, as the demand has kept full pace with the supply, and still remains unsatisfied.

A Wrong Statement Corrected.

"*San Francisco erected over 2,000 buildings last year, at an aggregate cost of* $11,000,000."

The above wild statement appeared in the local columns of the daily *Examiner*, January 6th. The information is entirely at variance with the facts as given in the columns of this journal, and there is no foundation whatever for the figures quoted. We have in our employ several whose sole duty it is to take cognizance of every new building erected. The values, as given in this journal, are approximately correct. In our December issue we gave the amount of work for 1883 as

803 BUILDINGS OF THE VALUE OF $5,261,689,

And this statement is as nearly correct as careful inquiry and conscientious attention can command. We notice the above merely that mechanics from abroad will not be deceived as to the amount of work in progress, and thus form wrong conclusions in regard to the value of building activities in progress in this city.

Testing Paints Ground in Oil.

A VERY simple test for determining the comparative value of any white paint ground in oil—namely, weigh out say 100 grains of each paint to be compared, add three drops of linseed oil to each, and spread them with a steel spatula on sheets of glass 6x12 inches as nearly as possible in the same manner. Place the samples thus prepared between yourself and the light, and you will have no difficulty in deciding which is most opaque. The sample which has obscured the light the most, or appears the darkest when held between yourself and the light, must have the greatest body or covering capacity.

THE *Architect*, of London, predicts an early revolution of taste in architecture, which, it thinks, may possibly result in a revival of Greek models. It notes decided symptoms of change in public feeling toward the recent craze for mediæval styles, and a decline in the popularity of "the very remarkable furniture fashion which has found its way into a certain ascendency in English architecture, under the name of 'Queen Anne'—more properly Low Dutch, and sometimes very low Dutch indeed." Lord Coleridge, since his return to England, has made public his opinion that the new Gothic law courts are "uncharacteristic, inappropriate and inconvenient," and, as the *Architect* slyly adds, the Lord Mayor has recently, at a Guildhall banquet, quoted Homer in the original, with a display of classic learning unusual in Lord Mayors. There are more substantial signs than these of the declining popularity of prevailing styles, and a growing regard for classic models; and this authority expects that the competitive designs for the new War Department buildings will include many examples based upon the Greek.

Bound volumes now ready. Price, $2.50 each.

San Francisco Chapter of Architects.

OWING to the regular evening for meeting following so closely the holiday season, the Chapter did not meet this month. It is expected that every member will be present at the next meeting. We are pleased to announce that the President has so far recovered from his indisposition as to be able to resume his usual business activities.

Our Exchanges.

WE have made arrangements with the editors of the following journals, by which we are enabled to offer quite a reduction to any one subscribing for any one of them in connection with this journal.

(The figures in parenthesis denote the price of the journals alone.)

CALIFORNIA ARCHITECT AND BUILDING NEWS.

Terms, $2.00 per annum.

With *American Architect* ($6.00), $7.00 per annum.
With *Builder and Wood Worker* ($1.00), $2.50 per annum.
With *Carpentry and Building* ($1.00), $2.50 per annum.
With *American Artisan* ($1.00), $2.50 per annum.
With *Brick, Tile, and Metal Review* ($1.00), $2.50 per annum.
With *Building* ($1.00), $2.50 per annum.
With *North Western Lumberman* ($4.00), $5.00 per annum.
With *Scientific American* ($3.20), $4.50 per annum.
With *Leffels' Mechanical News* ($1.00), $2.50 per annum.
With *Decorator and Furnisher* ($4.00), $5.00 per annum.
With *American Machinist* ($2.50), $4.00 per annum.
With *The Wood Worker* ($1.00), $2.50 per annum.
With *The Builder* ($2.00), $3.50 per annum.
With *American Inventor* ($1.00), $2.50 per annum.
With *Hall's Journal of Health* ($1.00), $2.50 per annum.
With *Cincinnati Building Review* ($1.00), $2.50 per annum.

We will add to the above list from time to time, as our arrangements are perfected with the publishers. We are prepared to furnish any journal printed at the shortest possible notice.

Wheeler's Patent Wood Filler.

WHEN this celebrated preparation was first introduced on this coast, it was recommended to give a perfect finish to hard wood. But by actual experience, it has been found to be equally applicable to redwood, and to the latter it gives a natural and perfect finish, such as is not obtained by the application of any other article. Its effect upon curly redwood is very fine. Such being its qualities, it should be used by every one who desires to have all the finishes of their houses present a smooth and natural finish. This FILLER can be obtained from the various dealers in paints, etc., throughout the city and State.

The "California Architect" is now in the Sixth Year of Publication.

Competition Designs!

ONE HUNDRED AND FIFTY DOLLARS

Cash Premiums!

FOURTH PRIZE,

Box of Drawing Instruments.

In order to promote a general desire to excel among Architects and Draughtsmen in the preparation of drawings for this Journal we have concluded to offer the following premiums for the best 4 designs of a Country Dwelling, the successful plans to be published in the CALIFORNIA ARCHITECT AND BUILDING NEWS.

1st, a Cash Prize of $60.00
2d, " " 50.00
3d, " " 40.00
4th, Box of Drawing Instruments.

Notice to Competitors.

All plans to be in the office of the CALIFORNIA ARCHITECT ON OR BEFORE the 1st of May, 1884.

All plans not accepted will be subject to the order of the owner, and will be returned upon receipt of the necessary postage.

We claim the right to reproduce in this journal all drawings of which honorable mention is made, and yet not entitled to a prize.

A *non de plume* to be used on all drawings; a letter to accompany the latter, addressed with the name used, containing also the real name and address of the contestant. This is done solely that the person's name and residence will not be known until the committee have made the awards.

A scale of ½ inch to the foot to be used.

Detailed estimate of cost to accompany the drawings. QUANTITY and PRICE of each material used to be given, so that allowance can be made for difference of price between the various sections of the East and this Coast.

Drawings are to show front, rear, and side elevations, with plans of the different floors.

The value of the house when finished to be ABOUT FIVE THOUSAND DOLLARS.

This competition is open to Architects in every portion of the United States.

Drawings to be made on card or bristol-board; to be line shaded; NO color but JET BLACK to be used.

All competitors will receive one year's subscription to this journal FREE, that they may see the various plans adopted.

The merits of the various designs will be decided by a committee appointed by the San Francisco Chapter of Architects.

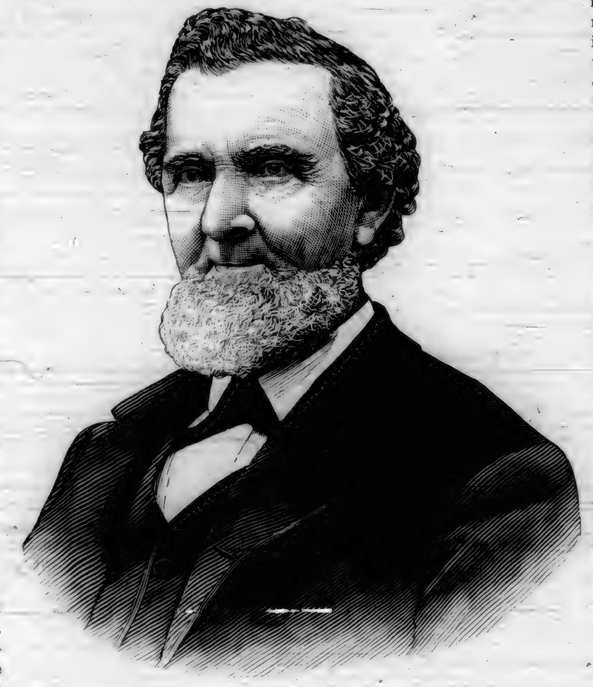
All inquiries in regard to the above will be answered by addressing a letter to the office of this journal, 240 Montgomery St., San Francisco.

WOLFE & SON, Editors and Publishers.

James E. Wolfe.

FOUNDER AND EDITOR OF THE CALIFORNIA ARCHITECT AND BUILDING NEWS.

HAVING completed arrangements which will enable us to produce monthly, two or more faithfully executed, life-like likenesses of the leading architects of the Pacific Coast, we commence our series in present issue with that of the founder, editor in chief, and joint proprietor and publisher of the CALIFORNIA ARCHITECT AND BUILDING NEWS. Our reasons for placing Mr. Wolfe first, is the fact that he was *first* to venture upon the unpromising task of establishing upon the Pacific Coast, a journal devoted to the Architectural, Construction, Sanitary and Kindred Sciences. His editorial work was commenced in 1879—the most discouraging, disastrous and unpropitious period within the history of the Pacific Coast, when all interests, public and private were crushed beneath the Hydra-Headed Monsters—Kearny-izm—Sand Lot-izm—New Constitution-izm etc., etc.,—when thousands of mechanics and others who had not thitherto known what privations and want were, were reduced to a state of actual destitution and suffering;—when the wheels of every clap of mechanical, commercial, manufacturing and other businesses turned slowly or not at all, and cheerful countenances were nowhere seen among the intelligent classes. It was during such times as these when this journal made its first appearance, and it required all the energy, determination, judgment and good management possible in one single individual, to overcome the surrounding difficulties, and bear the struggling waif safely through the terible period to more auspicious times. How well this has been done, aided since 1880 by the junior editor and business manager, the present standing and success of this journal fully attest.



JAMES E. WOLFE.

The subject of this notice arrived in San Francisco July 2, 1851, and therefore enjoys the many advantages of nearly thirty-three years personal experiences in the ups and downs, and exciting scenes of California life. During 1851, he devoted himself to architectural and constructive pursuits, but in 1852 was allured into a disastrous investment in a saw-mill enterprise, then located at the town of old Saucelito, Marin County, which swept away the accumulations,—the result of preceding financial successes. In 1855 he was attracted to the mines of California, and after several years spent in planning and constructing quartz mills in this State, and a sojourn of two years at Victoria, V. I., which was spent in architecture and constructive pursuits, he returned in 1861 to San Francisco since when he has devoted his entire time to the practice of the architectural profession, less part of 1863–64, when, with tens of thousands of others, he was drawn into the terrible vortex of the then *generally* unsuccessful mining enterprises which swept away fortunes—even mortgaged homesteads, jewelry and valuables of every kind, and impoverished perhaps one-half the entire population of this State.

Since 1861, Mr. Wolfe's architectural experiences have been extensive, and many fine edifices attest his qualifications as an architect. With a well preserved advanced age, his numerous friends will doubtless join in hoping that many additional years may be added to those already past, and that the columns of this journal may be made the more interesting by the product of his brain and pen. He is a member of the American Institute of Architects, and takes great interest in its proceedings. He is also one of the oldest practicing architects in the city. Mr. Wolfe was born in the city of Baltimore, Maryland, Nov. 6, 1820.

The Victory Is Ours.

WE have come up through five, and have entered upon our sixth year of publication work, including the quarterly of '79, and with each year have gained in every substantial particular; and as we have run along, we have endeavored to pick up and utilize the lessons and teachings of experience, being well satisfied that we are not yet too old to learn—to the end that we may be able to present to our patrons a journal of standard and increasing merit. This is, and will be, our aim and object, and we renew the pledge of former years, to continue our best efforts in making this—the only California journal of its kind—equal in every essential particular to the best of our Eastern or European contemporaries. We have secured a victory over the many things against which we have been required to contend, and are now well fortified to meet all reasonable probabilities of the future.

Our Advertising Rates.

THEY are published on first page of reading matter, and, unless for large ads, or small ones running a long time, we do not make any reductions. ON AND AFTER THIS ISSUE THE PRICE OF A FULL PAGE ADVERTISEMENT FOR ONE INSERTION WILL BE FORTY DOLLARS. For a longer period special prices will be given. Our large increase in circulation fully justifies us in this step. With improvements constantly being added, and with the aid of our next supplement, we expect and intend to gain at least ONE THOUSAND NEW SUBSCRIBERS this year. Material men will do well to consult us in regard to future contracts, as now is the time to make them, our busy season beginning in April.

A TOOL after it has been forged should be so hardened or tempered that it will never want to come to the fire again until it is so worn down that it requires reforging. This accomplishes two things: First, it saves the time lost in the second hardening; and in the second place, it avoids the damage always done to the cutting power by rehardening without forging.

A LARGE number of cases of diphtheria are reported in West Cleveland. It is supposed that the disease is caused by the stench from offal used as a fertilizer on a farm in that vicinity.

The Old House Altered.

BY A. CURTIS BOND.

With the accumulation of wealth and the assumption, whether understood or not, of the æsthetic and the *recherche*, the disposition is created to branch out and ignore to a considerable extent the humble, or at any rate unpretentious associations of our earlier life. In a degree this is not so strongly marked as it was a very few years ago, and many persons have discovered that the unpretentious may be made quite presentable, and fill the eye of the artist with pleasure, while retaining the delightful memories which do, or should, cling about the familiar objects of the past.

This tendency to tear down and build up again has been more universally shown in architecture, and especially the architecture of country houses, than in any other branch of art. So soon as the new heir acquired possession, he would renovate by removing entirely, and in place of the old-fashioned rambling, comfortable house, there arose a majestic affair of brick or stone or elaborately cut and painted wood. Thus, perhaps not from choice but from an erroneous idea that it is impossible to alter the old house so as to accommodate the new or the increased family, an expense is incurred, and a building is erected that may not possess any of the attractions of the old one. That this may be avoided in the majority of cases I will cite a short chapter in my own experience to show. I do not by any means claim that it is *always* better to re-make the present house in preference to having a new one. I only consider it frequently desirable, how frequently is a question that must be determined by the owner and his architect.

In my sketches I have shown the house as it was when it came into my possession, and as it probably had been ever since it was originally projected. The accommodations were not sufficient for a family of more than two, and in order to make it available for renting, a consideration of no little importance in our part of the country where no one is expected to live in one's own house, it was necessary to enlarge its capacity. Builders, friends of mine, advised me to clear away the property, tear down the cottage and begin all over again. The appearance of the thing was rather unpromising, I admit, and the suggestions of the builders were not entirely without their effect, for I felt very much disposed to do as they would have me. One day, however, I met another friend, an architect, a young man with all the fresh ideas of the nineteenth century about him, combined with a slight touch of the medieval, which latter trait, perhaps, prompted him to discourage my iconoclastic scheme of destruction and urged the renovation of the existing wreck. There were only four small rooms in the entire building, but the architect figured and planned so that he evolved six goodly sized apartments, and in addition a snug bath-room large enough for all the practical uses to which a bath-room is put (see sketch). As the cost of these alterations was certainly one-third what the building of a new house, even on the same unpretentious scale as this one, would be, it was decided to try the experiment. The success of the scheme may be measured by the accompanying illustration, where is shown the old and the new in excellent contrast; the renovated house is by no means elaborate or showy in its appearance, but it is very comfortable, has many pleasing features, rooms that are capable of easy and attractive furnishing and decorating. That the relative conditions of the two places may be judged it might be well to give a short description of both.

The old house had a short hall entered immediately from the front door; from this hall doors led into the dining-room on one side and the parlor on the opposite side; adjoining the parlor was a bed-room having a closet, and off of the dining-room was the kitchen, with a closet built box-fashion in one corner of it. the stairs leading to the attic were an eye-sore in every sense, clumsy, rickety and delapidated: they were boxed off of the dining-room making a very illy shaped room with seven corners; from the kitchen a door lead onto a plain board stoop of three or four steps. Marauding boys had appropriated the outside shutters and made the house a target for their mud balls, so that the paint was hardly discernable, and the weather had united with the boys to make awful havoc.

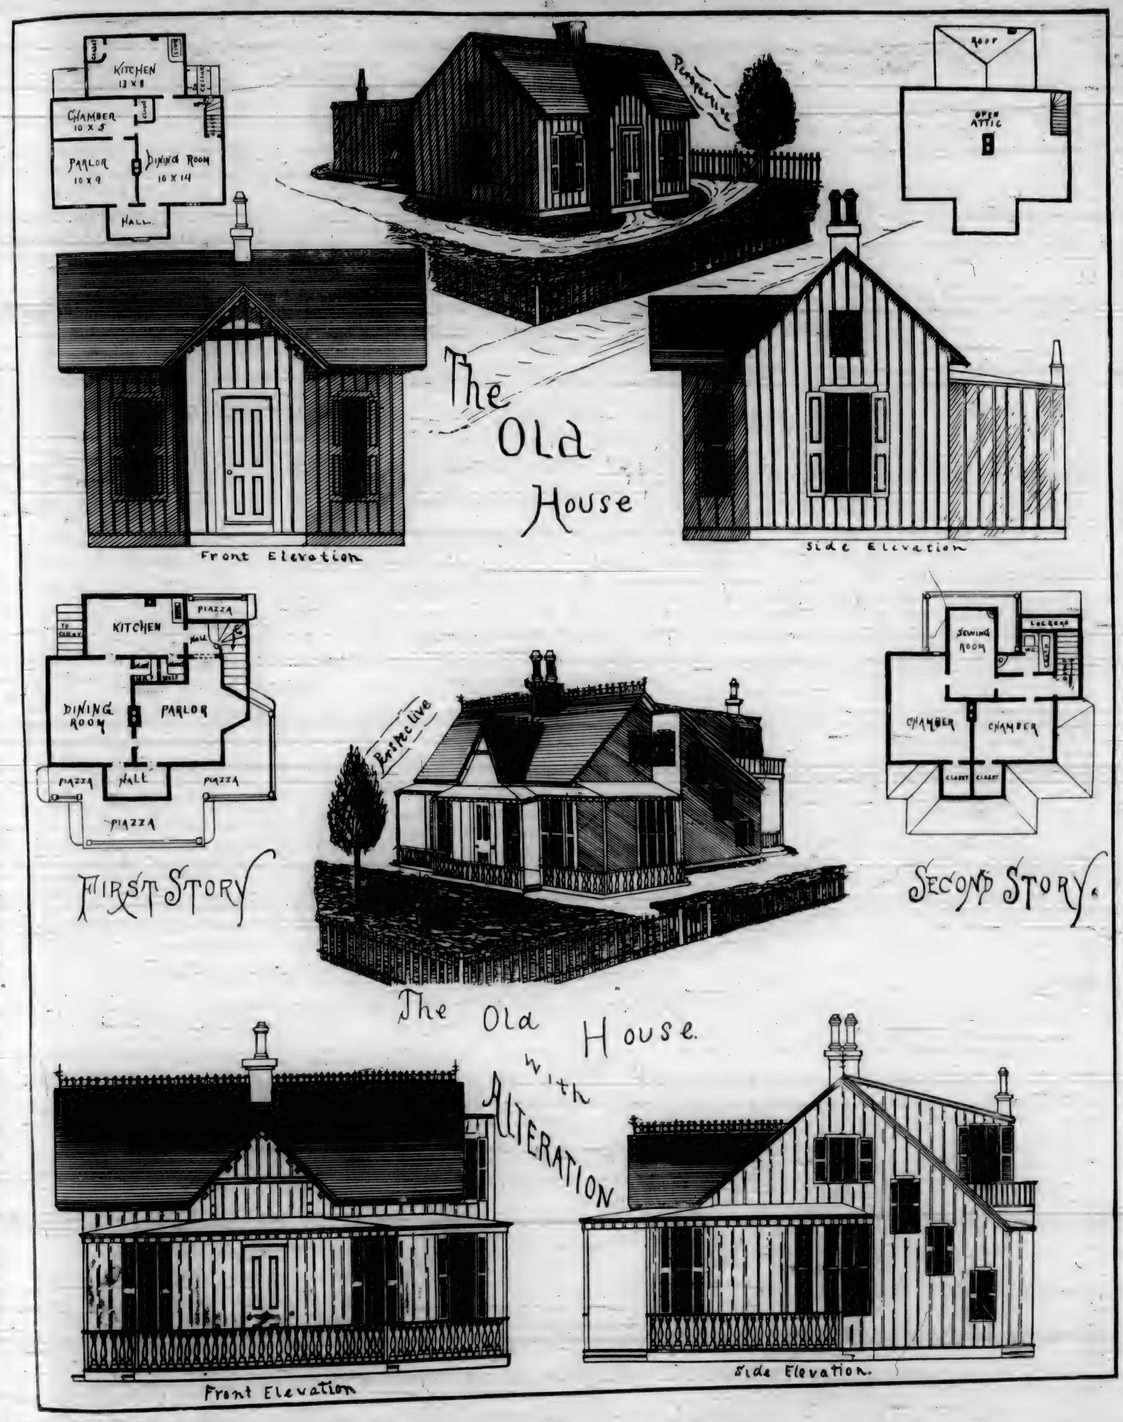
That was the condition of the building when the architect commenced on it. He began by removing the partition between the parlor and the bed-room directly behind it, making thus one large room which was transformed from the old parlor into a new dining-room. The door which led into the kitchen was left as it had been, and the closet that belonged to the bed-room was utilized for a dining-room pantry; in the rear partition of this pantry a small window or slide was cut, intended to pass through dishes to and from the kitchen. Another pantry similar to this one already built was put at the back of the first one and extended on a line with it into the old dining-room. This second pantry opened by a door into the kitchen, and through the slide or small window communicated with the original pantry, and so with the dining-room. The boxed-in stairs were then removed from the old dining-room and upon the outside of the house, at the side of this room, an extention was built extending to the rear of the house and then following it around until it stopped at the kitchen L. From this extension the stairs which were removed from the old dining-room, are contained and the old dining-room itself becomes square, as is shown. This extention is built out a little over four feet. These stairs from the floor above, turn with a landing and end in the further part of the extension, where is formed a small square hall, having a door at the very foot of the stairs opening onto a back porch, a door opposite the stairs leading into the kitchen and the other side of the square an arch is hung with a handsome *pertice* and discloses the parlor door. The newel post at the foot of the stairs is pretty and effective, and long, narrow windows, having the same rake as the stairs, extend up to the floor above. The end of the extension at the side here is finished out with a slant making a bay-window in the parlor; this bay appears from the interior to contain three windows while in reality there are but two; the third side being a glass door opening to a closet under the stairs. When circumstances seem to warrant, this closet can be converted into a stair leading down into what is now a cellar but which might be made, with very little expense, a basement.

The old closet in the kitchen was removed, the old door changed to a window having beneath it an entrance to the cellar, and a door cut at the rear of the room. Around the entire front and side having the new extension, has been put an attractive piazza, covered and with a balustrade.

The open attic was partitioned off as shown on the plan and an extension built over the kitchen making a nice sewing room with a balcony from the window. Over the extension built for the rear hall is located the bath-room and water-closet, being almost directly over the sink of the kitchen, bringing thus all the water arrangement of the building together and saving considerable in the matter of plumbing bill.

The ceilings and walls were cleaned and covered with white muslin to secure a smooth surface, upon which was laid a neat wall paper with a pretty all-over design, a suitable dado and frieze; the rough board floor was all cleaned off and the floor laid carefully with the following: The boards, being thoroughly cleaned and planed, had the holes and crevices filled with paper putty made by soaking newspaper in a paste made of wheat flour, water, and ground alum, thoroughly mixed. With this same paste then the entire floor was coated uniformly and smoothly, and upon it was laid a thickness of manilla paper, over which another layer of paste was placed and a second thickness of manilla paper put on. This was then allowed to dry perfectly, and finally a thinner layer of paste was applied, over which a layer of fine pattern wall paper was laid and pressed hard. This paper was then sized with a sizing composed of one-half pound of white glue and two quarts of hot water, and when thoroughly dry finished with hard oil and varnished. This gave a floor that was firm and hard and bid fair to be lasting.

In this manner was the old structure made over into a new place. It is neat, tasteful, and inviting, and it has well repaid the investment in the satisfaction given in looking at it. This same result can no doubt be attained by many houseowners, and I hope the experience may be of some value to a portion of my readers, but I would impress upon them that it is necessary in order to bring about this most satisfactory conclusion, to have the aid of an intelligent architect and a conscientious builder.



Something about Shrinkage.

THERE is but very little material that keeps the same size under all circumstances. Metals shrink and expand—some very much more than others—according to change of temperature.

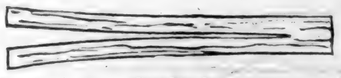
I don't wish to treat of the shrinkage of metals in this article, but wholly upon the shrinkage of woods. Like metals different woods vary much in shrinkage. But all woods of the same variety will shrink in size, in proportion to the amount of water or sap contained in the wood. One variety of wood may contain four times the quantity of sap and still not shrink near as much as others. Lumber sawed from trees growing on a side, hill, or near the water, or on the south side of a grove, will shrink very irregularly. Some parts will shrink very much more than others, more particularly endways. The same is true with a tree that grows very much out of perpendicular. Suppose a tall tree was growing at an angle of 45°, the tree itself being perfectly straight, as soon as the tree was cut down, it would partially assume the shape of a rainbow.

Nearly all lumber shrinks more or less endways. Some lumber will shrink on one side and expand on the other the moment it is sawed. This is very noticeable in sawing lumber from logs. For instance, the first board sawed from a log may be longer than the log, or *vice versa*, according to which side the sawing was commenced.

It is also very noticeable in ripping up lumber; sometimes, when the saw gets well into the board, it begins to *pinch* and has to be wedged, but after the saw gets nearly through the cut, begins to open as illustrated in cut No. 1.

CUT NO. 1.

Or it may open instead of pinch as shown in cut No. 2.

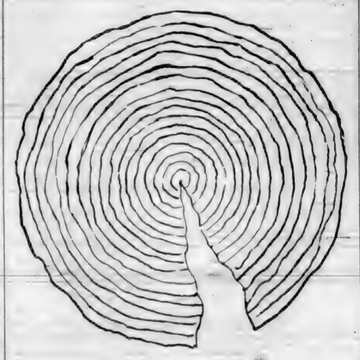


CUT NO. 2.

This is all done by shrinkage and expansion. In No. 1 the inside shrinks while the outside expands; and in No. 2 exactly the reverse. We will suppose that No. 1 and No. 2 each represents a board 12 or 14 ft. long, 1 inch thick and 12 inches wide. Now if a piece one inch wide is sawn out of the center of No. 1 the piece would be shorter than either side; and if the same had been done to No. 2 the piece would be longer. Straight edges can never be made of such lumber.

It is doubtful if there is any lumber known that shrinks as much endways as redwood. That wood shrinks on an average ¼ of an inch in 12 feet; but there are cases when it is four times that amount. When window-casings are nailed to green rustic, oftentimes the latter in shrinking will pull the frames open and let the sash out.

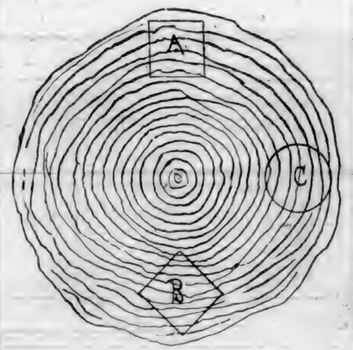
I wish to show now *why* lumber checks in seasoning. Nine-tenths of all the cracking or checking in seasoning lumber is caused entirely by LIGHT and not by HEAT. Lumber can be seasoned very rapidly by intense heat, without even a check, provided not one ray of light is allowed to reach the lumber during the process of seasoning. I also wish to show why a log will split while seasoning. For example, let me take a section of a green log of madrone, blue gum, or any other of that class of woods (which comprises at least one-half of the woods known); we will take a log 18 inches in diameter and saw off a section 6 inches long, and let it season (in the dark if you please).



CUT NO. 3.

Here we have it at cut No. 3, thoroughly seasoned and find it about the same diameter and circumference that it was before seasoning; we find that the depreciation in size lies in the V-shaped cleft; and this cleft is caused by the wood shrinking very much in circumference, and in diameter hardly perceptible, consequently the fiber must be torn asunder.

To illustrate this more fully we will take another section of the same log and cut three pieces out as shown in No. 4, two pieces being 4 inches square, and 1 piece round and 4 inches in diameter.



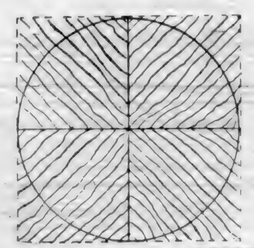
CUT NO. 4.

We find them as shown after seasoning to be in the shape as shown in cut No. 5.

CUT NO. 5.

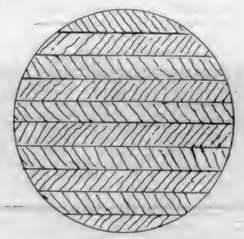
We find that A has shrunk in width at the top ¼ inch and at the bottom 5-16 inch, while from top to bottom it has only shrunk 1-32 inch. B we find has shrunk from right to left ⅜ inch, while from top to bottom it has only shrunk 1-16 inch, which leaves it in the shape of a diamond. C we find to be egg-shaped; the longest way has shrunk 1-32 inch, while the shortest has shrunk ¼ inch. "Well," says one, "what are we to do about this shrinkage, we can't help it, can we?" That is very true you can't stop the wood from shrinking, but you can help using that shrinkage in the wrong direction.

Suppose you have a solid cylinder to make, say 12-inch diameter and 3 feet long, to be and keep perfectly round. This cannot be made of one piece (even if you had it), neither can it be made of several pieces, unless glued up in the right manner, and with the right kind of lumber, or with lumber having the grain the right way, which should be at an angle of 45°. It makes no difference how many pieces are used, provided there is no less than four.



CUT NO. 6.

Cut 6 is a section glued up of 6-inch square timber.



CUT NO. 7.

Cut 7 is formed of 1¼-inch plank glued together with the grain running like either No. 6 or 7; once made it will always keep round; whereas if the timber is put together with the grain running as it did in the log, it will not make so good a job as if made of only one piece.

The reason that articles made of *pieces* glued together will not warp and twist as much as if made of one piece, is owing to the MIXING of the grains, which generally gets mixed more or less, but without any regard to it on the part of the workman.

Wood-workers, bear this in mind,—wood shrinks in circumference of the grain, but comparatively nothing in diameter.

Santa Clara. E. H. DAVIES.

How to Square a Circle.

NEWARK, December 13, 1883.

EDITOR CALIFORNIA ARCHITECT AND BUILDING NEWS:

To square the circle is to find the circumference when the radius is given, and for effecting this it is necessary to know the ratio of the diameter to the circumference.

To find the circumference when the radius is given Geometrically:

FIG. 1.—Let C S equal the radius; from the points C and S as centers, describe the circle and arc C D; tangent to the arc and circle draw D P. Join S P; at right angles to S P draw L M tangent to the arc D C, and M J equal M L parallel to S P. Then D J equals one-fourth (¼) of the circumference of the circle, and S J equals the side of a square equal in area to the area of the circle.

To find the ratio of the diameter to the circumference:

Divide S B, the diameter, into fourteen equal parts, eleven of the parts equals D J or one-fourth of the circumference, multiplied by four equals forty-four divided by two equals twenty-two; fourteen divided by two equals seven; equal to seven twenty-seconds, the ratio required.

L. D. GOULD.

A Liniment for Rheumatism.

THE *Quarterly Therapeutic Review* says, mythyl salicylate (oil of wintergreen) mixed with an equal quantitiy of olive oil or linimentum saponis applied externally to inflamed joints affected by acute rheumatism, affords instant relief, and, having a pleasant odor, its use is very agreeable.

Bound volumes now ready. Price, $2.50 each.

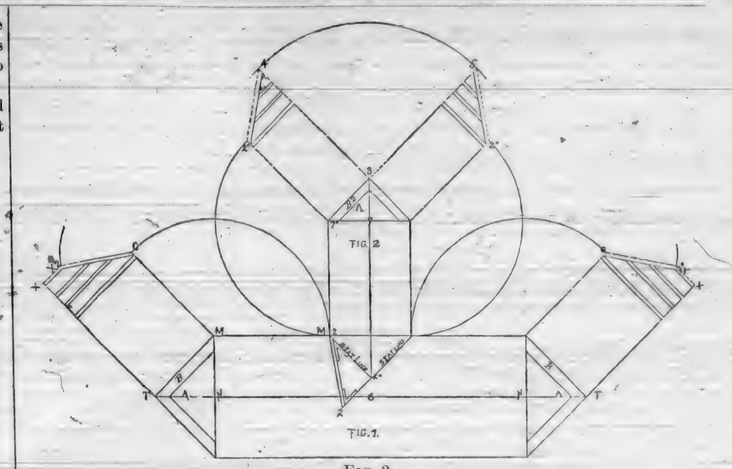

FIG. 2.

A Graphic Method Showing the Cuts and Timbers in Position, over Unequal Ground Plans and Unequal Pitches of Roofs.

A A A ARE elevations to their respective ground plans. B B B2 are the common rafters.

Square from the back of the common rafters B B B2 as shown and take the distance 6 N in the compass at Fig. 1, and stand on the point of gable at T and describe a circle at X X on both ends.

Now square down indefinitely from X T to X2 both ends. Set the compass to the distance M M. Stand at M; cut M C at both ends.

Set compass to the distance found at seat line, namely, 2 2 in the compass, and stand at C, cutting X2 that has already been indefinitely squared from X T at both ends, then C X2 and C X2 will be the valley rafter to stand correctly over seat line.

FIG. 2.—Make elevation and square out from back of common rafters. Set the compass to the distance 7.6ᵂ. Stand at 3 on the point of the gable, cutting 4 and 5, take the distance 7ᵂ 2 and describe circle, cutting 2ᵂ, then 2ᵂ 4 and 2ᵂ 5 are the correct lengths of valley rafters to stand in position over ground plan. Cut along the dotted lines. Hinge on the back of the common rafters at B B B2. Also hinge on the plate lines at N N and 7. Now fold up and you will have the covering of building with all the timbers and cuts in position. The bevels are shown on the ground plan.

The above and other cuts I have called the attention of the professional architects, engineers, and builders to, and have received their warmest indorsement, as being the most simple and ready way of illustrating constructive carpentry ever exhibited. M. J. MARION.

It is especially desired that all subscriptions begin with the month of January. Promptly forward amount of same, so that you will have a full volume at close of year.

How to Use a Hammer.

THE following floating paragraph appears to supply a long-felt want: Those who "never can drive a nail without splitting the board" may readily overcome this. Looking at a nail you will perceive that for some distance under the head the nail is broader than it is below; now a nail must always be driven so that this broad side is on a line with the grain, not at right angles to it; if at right angles, the wood is sure to split, as every blow with the hammer tears apart the fibers; whereas, if the nail be driven with broad side on a line parallel to fiber or grain of wood, the broader part wedges in lengthwise, and makes the nail hold strongly. To drive a nail well, however, needs practice. Never get a cheap iron hammer, such a one as you will see lying in a tray in front of a Cheap John hardware store, at 25 cents, having only an iron face; the striking surface soon becomes rounding, and one is as likely to crush a finger or mar the surface of the wood as to drive a nail home with such a hammer.—*Building.*

TO REMOVE INDIA-INK MARKS.—Blister the part with a cantharides plaster a little larger than the mark; then keep the place open with basilicon ointment for a week finally dress with simple ointment to heal it As the new skin grows, the tattoo will disappear.

A HOME-MADE FOUNTAIN PEN.—Take two ordinary steel pens of the same pattern and insert them in the common holder. The inner pen will be the writing pen. Between this and the outer pen will be held a supply of ink, when they are once dipped into the inkstand, that will last to write several pages of manuscript. It is not necessary that the points of the two pens should be very near together, but if the flow of ink is not rapid enough the points may be brought nearer by a bit of thread or a minute rubber band.

San Francisco Chapter of Architects—Its Aims and Its Objects.

MANY of the leading members of the architectural profession on this coast have long been solicitous in regard to a lack of a proper school and other facilities, through which students connected with the different offices could receive instruction in the principles of the art to which their time is devoted. To meet this want, and to secure a united and harmonious action and friendly feeling among the members of the profession, are two of the principal reasons for the formation of the San Francisco Chapter, American Institute of Architects.

With the system now in vogue, the pupil meets with a serious drawback from the first start in his career. As a general thing he is placed in an office and allowed to shift for himself. Beginning with *tracings*, and gradually working up to *details*, his mind receives the ideas alone of the one for whom he may be working, and they become, as it were, inculcated in his brain, so that in after years he but reproduces in a modified form, the designs of him under whom his apprenticeship has been served. His thoughts have been led in one continuous and perhaps monotonous channel, and he becomes incapable of exemplifying the two greatest lessons to be learned, *beauty* with *originality*.

The art of any undertaking being first its aim, and next its manner of accomplishment, it may be asked, By what means does the Chapter propose to better the conditions of the student, so that his mind may be free to receive thoughts calculated to do him most good?

In the first place, classes have been formed in the various departments incident to a thorough knowledge of architectural science, and competent and willing teachers have been found, who have made their work a labor of love. In perspective, flat drawing, modelling, carving, geometry, and other branches, thorough instruction is weekly given to rapidly growing classes, and this without a cent of cost to the student. Nobly have some of the first members of the profession given one night each week to this object, that the members of the classes may receive the true fundamental principles of their calling. This is what the Chapter has already done.

In the second place, it is the intention in the near future to place before the students a prize that will be eagerly competed for, and when obtained be held as a memento symbolizing devotion to art. To set apart a fund that shall be devoted to him who, in a certain period of time, shows the most marked improvement, enabling him to visit the Old World and study the works of the great masters. The question may be asked, Of what use is it to those that remain, that *one* should be selected to go abroad, and be enabled to perfect himself in the architectural profession, while those that studied equally as hard, are compelled to follow on for another period in the same beaten tracks?

We answer, Do not follow the "beaten tracks." We propose that the one who is fortunate enough to gain the name of the "traveling student" shall, before he starts on his journey, enter into an agreement by which his progress from time to time shall be communicated to the Chapter. He must, as occasion offers, forward sketches of different phases of architectural beauty, with which he may come in contact; these, with his correspondence, to be placed before the regular meetings of the Chapter. Thus, those that stay behind will have a new avenue of thought opened to them, and each successive competitor be enabled to stand higher in his examination than his predecessor. The Chapter reserves the right to watch over the conduct of the successful candidate, and while traveling, if he should stray from the right path, have the power to withdraw its patronage.

Mr. C. A. Adams, in his address before the Architectural Association of London, thus speaks of the benefits derived from the younger members of the profession joining a Chapter: "He joins the Architectural Association, and there finds an organized system at work, inducements for study, and if he enters his name on the lists, friendly rivalry and competition. If he has anything in him, he is sure to get on, and win his way without fear or favor, and in the struggle with his fellows, finds his level, and measures his strength with his antagonists in friendly encounter."

Are we aiming too high in our endeavors to excite the ambition of students connected with the Chapter? We think not. Already two prominent gentlemen have signified their intention of placing at the disposal of the Chapter, the sum of FIVE HUNDRED DOLLARS EACH, to enable us to carry out the idea mentioned, and we have no doubt others will be found equally as willing to assist. It remains for the Chapter, as well as the individual members thereof, to so exert their endeavors to promote a general good feeling among those connected with the profession, that the lovers of true art will gladly welcome the opportunity to subscribe to a fund for the general advancement of the young students."

(To be continued.)

How to make a rattail file that will cut faster and last much longer than any cut file ever made: Draw out a piece of steel to the size you want the file to be. Make it square and tapering to a point at one end; then twist it like any auger, but closer; heat it to a dull red, and chill it in water, dipping it straight down. Draw but little temper. You will be surprised to find how fast it will cut and how long it will last.—*Blacksmith and Wheelwright.*

THERE is a tooth pick factory near Harbor Springs, Mich., which annually consumes 20,000 cords of wood.

Subscribers will greatly oblige us by forwarding promptly the amount of their subscription.

The Uses of Turpentine and Benzine.

TURPENTINE spirits is derived from the turpentine extract of several species of pines. It is used in medicine. There are many liniments which owe all their virtue to this spirit. Benzine is a spirit distillation of petroleum and is used in the arts and manufactures. Turpentine as used by painters is called a thinner, to dilute oil paints for inside work, or it may be used alone as a vehicle for flat or dead colors. All paint mixed with turps dries quickly, and when oil is added the drying is slower, leaving a gloss proportioned to the quantity of oil used. The use of boiled oil darkens light paints by giving them a yellow shade on all interior work; for this class of paints, raw oil is used with turpentine, white japan, or sugar of lead. The effect of benzine turps in painting is too rapid drying, it being too volatile as a vehicle to hold the mixture in easy solution while spreading the pigment. Where benzine is used in painting it should be compounded lightly with oil paints, as this retards its action and allows the painter sufficient time to flow the color before it can set. Its use in oil paints is much less injurious; it causes the drying to be more rapid, and does not affect the gloss as much as turpentine spirits. In all outside exposures, when painting, this mineral turps should only be used as a dryer and lubricant of the oil paint in use. In such work, the presence of this dryer is of so short a duration that the paint soon sets and dries with an even gloss, whereas, when turpentine is used, being of a much stronger nature, it cuts more literally the filament of oil, and the consequent result is the impairment of the gloss finish. Then again when painting in the shade, oil paints are more difficult to spread than when the warm rays of sunlight are present to suffuse the work with its gentle heat. It is here a volatile lubricant is needed to do for the oil what the solar rays does on work, and benzine is the only turps that as yet the laboratory has evoked, that will do this without any disadvantage to work done in the shade. In cold, chilly weather, when the paint inclines to thicken from frost, a liberal use of benzine turps will enable the painter to spread the color with more freedom and yet not impair the general effect of the work. In varnishes of the lower grades, when manufactured with benzine, it plays a very important part, for the B varnish is made more serviceable to the artisan. In all lacquers its working is so rapid that the fluid color is laid instantly on metal goods without a blemish. Turpentine varnishes, if diluted much, lose the beauty of their gloss. Oil in this kind of varnish, when added by the workmen, leaves a sticky surface and is detrimental and is not safe to use. In housework the benzine furniture grade can be diluted with pure linseed oil in a fair proportion, and it will give an elastic coating of a high gloss of great endurance, equal to some foreign elastic brands.

J. W. C.

Augustus Laver.

To this gentleman does the San Francisco Chapter of Architects, in a great measure, owe its successful standing as one of the most prosperous in the United States. In the early part of 1881, he was elected President of the Pacific Coast Association of Architects; not content with a local organization from the outset, Mr. Laver labored earnestly to make the Association a branch of the American Institute. Being the only member of that body residing in this State, it was impossible to form a Chapter without new members were added to the parent institution, sufficient to form a branch in this city. It was by Mr. Laver's efforts and recommendation that six of our leading architects were enabled to join the American Institute, and thus form the nucleus for the present chapter.

Mr. Laver, wherever he has been, has always been identified with the leading societies in the locality in which he has resided. At present he is a Fellow of the American Institute of Architects, the Institute of Engineers of New York, the Institute of Engineers and Architects of Montreal, and for eighteen years a Fellow of the Royal Institute of British Architects, of which he has been made an Honorable Fellow, and corresponding member. A thorough, constant and enthusiastic student of all the details of his profession, his advancing years promise to bring only greater eminence and success in the art to which he has devoted the best energy and interests of his life.

AUGUSTUS LAVER.

Mr. Laver was born in Folkestone, England, on Sept. 20, 1834. Previous to his coming to the United States, he practiced his profession in London, principally in the service of the British Government. In 1857 he came to the United States and settled in Ottawa, Canada. There his professional ability soon gained him distinction, and shortly after his arrival (the Queen's decision making Ottawa the seat of government) he won the first place in an open competition, and was employed, with his then partners—Thomas Fuller and Mr. Stent—by the government to design and erect permanent legislative buildings. The corner stone of this structure was laid by the Prince of Wales on September 1, 1859. Many other buildings lay claim to his ability, principal among which was the remodeling of the Roman Catholic Cathedral of Montreal. After leaving the Canadian seat of government he again became professionally associated with Mr. Thomas Fuller, of New York. While associated with that gentleman, they conceived the plan, and carried into execution, the construction of the magnificent building known as the State Capitol at Albany. Over twenty millions of dollars were expended on this superb structure.

About this time the growing opportunities of the Pacific Coast attracted Mr. Laver's attention, and in the fall of 1870 he settled in San Francisco. The work which has brought him most prominently before the citizens of this coast, and the best evidence of his architectural ability, is the New City Hall of San Francisco. Mr. Laver entered the open architectural competition established at the projection of that work, gained the first position among the many competitors, and the buildings erected from his designs are rapidly approaching completion.

Mr. Laver's skill as a designer of country residences has shown itself in the palatial mansion erected by J. C. Flood, at Menlo Park. The O'Brien memorial monument also claims Mr. Laver as its author. He is also now engaged in preparing the plans for the large mansion shortly to be erected on Nob Hill for Mr. Flood.

Mr. Laver resides in one of the pleasantest parts of the city. His wife is a relative of the eminent English statesman,—Charles James Fox.

To the student seeking information, Mr. Laver finds a share of his always engaged time, to impart such knowledge as the applicant desires to gain. His professional standing and large connection with important public works have caused him to be intimately acquainted with scientific and literary men, both at home and abroad, and there are but few better able to give information on all subjects connected with the architectural professions.

During the past year, Mr. Laver has unfortunately been compelled to keep to his house in the evenings, the cool weather generally experienced having a tendency to aggravate a trouble connected with the bronchial tubes. Thus the Chapter has missed the benefit of his experience; but at all times he has been ready to meet the various committees of which at times he has been appointed a member, and none are more willing to give counsel upon all subjects that have a tendency to elevate the standing of the youthful members of the Chapter, or to give information that will lead to a more thorough organization among the older members.

Although many of Mr. Laver's buildings and mansions—since his residence in this city—have been of the more costly style and imposing appearance, it must not be inferred that these alone receive his attention. Many of the picturesque cottages that adorn our valleys and sanitarium resorts, are the result of his study; and in the quiet nooks of Marin and other counties, are found examples of suburban architecture, the designs of which were the result of the labors of the gentleman under consideration.

John Wright.

PRESIDENT OF THE S. F. CHAPTER.

No more positive proof of rapidly increasing refinement need be asked than that furnished by the increasing number of architectural constructions which are fast making this city the equal of any in the United States. For a long time men were too busy to think of these graceful adornments, but that period has gone by, and the architect's genius has full scope in designing stately mansions and edifices. The firm of which this gentleman is the senior member has done much to elevate the tastes of our people to a higher order of architecture, and many of our imposing public buildings are examples of the skill with which all the details of a structure may be handled.

Aside from his reputation as one of the master minds in the handling of architectural studies, John Wright has made himself respected by the draughtsmen all over the coast. His main idea seems to be the elevation of the student to the higher grades of the profession. To him is mainly due the formation of the classes now being so successfully conducted by the Chapter. He is nobly giving a portion of his really valuable time to laying the foundation of a plan by which the Chapter can successfully institute a TRAVELING STUDENTSHIP, for the benefit of one who shall prove himself to be the most studious, competent, and original scholar connected with the classes under the auspices of the Chapter.

Mr. Wright is a native of Scotland, and was born May 15, 1830, in the town of Killearn, Scotland. In him was born a natural love of the beautiful, and this feeling has been cultivated more and more as he has reached maturer years, until we see it exemplified in the structures over which he has exercised control.

In 1866 the present firm, of which Mr. Wright is a member was established in this city, and for many years it has remained in its present location. From the number of buildings erected by the firm in various parts of the city and State, its name is very well known by those owning property.

Mr. Wright has been intimately identified with the San Francisco Chapter of Architects. After its establishment, he was its first President, being elected to that position by a unanimous vote. Such had been his zeal for its welfare during his term of office, that, at its annual meeting, held in September, 1882, he was again elected President, which position he now holds.

The Toland Medical College, the Eagle Block, Dunham, Carrigan's fine building, the State Insane Asylum at Napa, Deaf, Dumb, and Blind Asylum at Berkeley, First Congregational, Calvary, St. John and other churches in this city, and many of our prominent dwellings lay claim to the architectural ability of which Mr. Wright is a member.

Mr. Wright is a man of powerful physique, and his resemblance to one of the nation's honored martyrs is very striking. He also possesses the largest and most complete architectural library of any one on the coast, and none are more truly happy than the subject of this sketch when placing the same at the disposal of those seeking information in the higher branches of the beautiful study of architecture.

JOHN WRIGHT.

Mr. G. H. Sanders is associated with Mr. Wright in business matters; that they may long live to continue their successful career is the wish of all with whom they have come in contact, socially as well as professionally. Mr. Wright is a member of the American Institute, and is a careful student of the various movements made by that body. Particularly noticing the measures instituted by the various chapters belonging to the parent institution, for the benefit of students and draughtsmen, he seeks to introduce those that are the most applicable to the younger members of the profession on this coast.

Practical Notes.—A Place to Leave Orders—Learning to Keep Tools in Order.

THE other day I dropped into a carpenter's shop to have a little job done, but found only the apprentice boy present. Making inquiries as to when the "boss" would be in, the boy without looking up from his work said, "Don't know." So I started off to find some other place where I could have my wants attended to.

Owners and managers of any kind of business where they are liable to have frequent calls from the public, ought to leave word when they expect to return to their usual place of business, and if no one can be left to answer such questions, a slate and pencil don't cost much and when put in a convenient place so that orders can be left, confer a favor on the customer and bring dollars and cents to the workman.

As I stood looking at the boy, he was trying to "jack off" the rough side of a two-inch plank, and despite his earnest efforts he did not make much headway. The foreman had given him an old wornout jack plane that had been thrown aside as not fit to use.

I don't agree with a great majority of master-workmen that any tool is good enough for an apprentice. In my judgment an apprentice should be provided with a good serviceable tool. Undoubtedly, not knowing just how to use it, he may soon get it out of order, but one of the first lessons he ought to receive should be how to put his tools in order.

I beg to ask any apprentice if he was ever shown how to grind a plane-iron by the foreman, and then how to put an edge on it by rubbing it on the oil-stone. I venture to say that not one apprentice in a thousand is so instructed. The fact is a boy is supposed to pick up how to do such things. If employers would pay a little attention to the instruction of their apprentices at the outset, it would pay them in the end because they would learn to do better work in much less time than they do now.

No workman can do a good job with dull tools, and one reason why there are so many "barn-joiners" is because no one has taken the trouble to teach them how to keep their tools in order.—*Rivet, in the Mechanical News.*

A GAS explosion took place in a hotel in Lincoln, Eng., recently, attended with great damage to the building. The explosion followed immediately upon a person going with a light into the cellar under the bar.

William Curlett.

VICE-PRESIDENT S. F. CHAPTER.

THE charm of a city depends in a great measure upon the number of mansions and edifices upon which the skilled architect has been allowed the full scope of his designing powers, thus enabling him to establish his claims as a true artist.

A sudden increase of wealth and culture among the inhabitants of any city, always creates a demand for buildings to suit their tastes, and to meet this demand many gentlemen of professional ability are attracted from older cities; and it is when these become stationary, and their names are known throughout the State, that the people recognize the fact that all such have been true lovers of art and have come to their place that they may be indentified with the true and beautiful in architectural science.

Mr. Curlett, the subject of this sketch, was among the first to unite in the movement which resulted in the formation of the Pacific Coast Association of Architects, with Mr. Augustus Laver as President, which association has since been merged into, and its members now in part constituting S. F. Chapter of Architects. In all the movements of Association and Chapter, Mr. C. has manifested a becoming degree of zeal and enthusiasm, and by words fitly spoken, and generous, cordial intercourse, placed himself among the most esteemed of the Chapter members; as an evidence of which, he was elected First Vice-President in 1882, and reelected to the same position in 1883. He is one of the number who advocate the more enlarged and far reaching purposes of the Chapter, in the establishment of a "studentship,"—a prize worthy the highest ambitions of the young men in the profession, and which from present indications is likely to be attended with permanent success; also the several other measures in contemplation by which the grand influence and benefits of the Chapter work will be made clearly manifest. Mr. Curlett was born at Warrenpoint, Ireland, on the 3d day of March 1845, and being in the full enjoyment of a vigo ous physical manhood, good intelligence, pleasing manners and fine social qualities, he has before him the promise and prospect of more than ordinary success in his profession. Being an earnest student and devotee of the sublime art—architecture—his conceptions as illustrated in buildings lately finished by him and those nearing completion, sustain his claims to a very enviable position among the architects practicing in San Francisco.

Mr. Curlett's career has been a very successful one. In 1876 he became associated with Mr. A. Laver in a professional capacity; among the most important works designed by that firm during their association was the country residence of J. C. Flood at Menlo Park. Their partnership was dissolved in 1880.

Upon the expiration of the time for which this partnership was formed, Mr. Curlett was on January 12, 1880 elected to the position of architect to the School Department of the City of San Francisco, which position he held for a double term. During that period, he designed many notable buildings for the department. The State Normal School at Los Angeles is indebted to the talent of Mr. Curlett, he having designed and superintended its construction.

Mr. Curlett is now located in the Phelan Building, a section of the city that will, in our judgment, soon he adorned with buildings of large dimensions and imposing appearance. It is not our purpose to make any unwarrantable statement in reference to any of the gentlemen, whose likenesses appear in the present, or may appear in subsequent issues of this journal. It would not be wise so to do, as such a course would simply compromise and lower the status we have in view, and place us at a disadvantage. Neither would such a course be acceptable to the gentlemen interested, as flattery and statements in excess of real facts, would be simply obnoxious to practical minded, intelligent men.

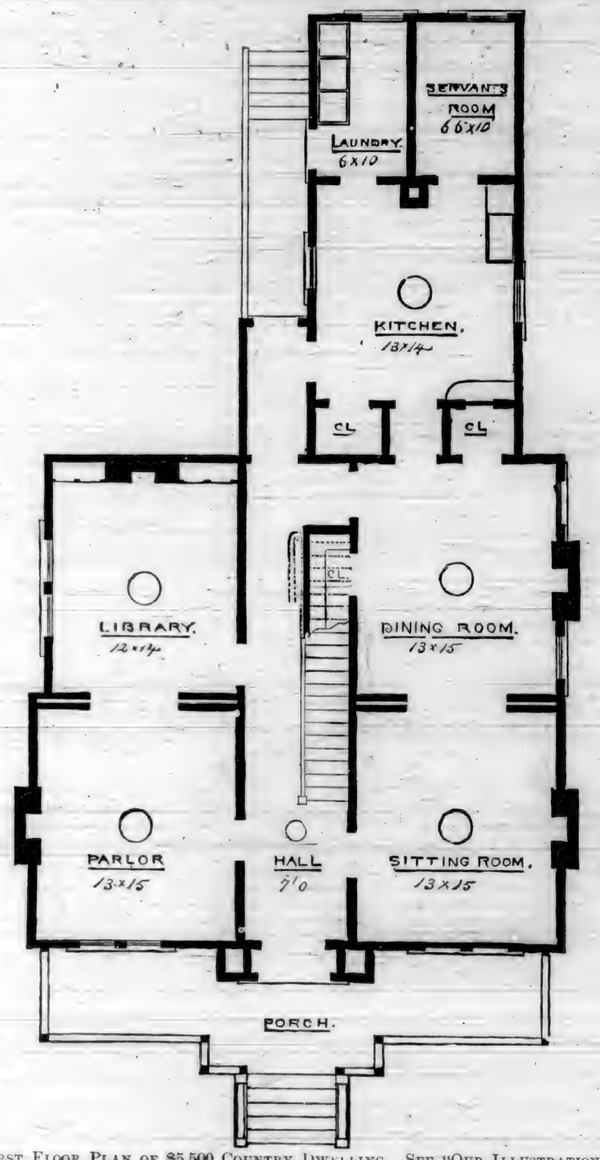
We have placed the officers of the Chapter first, as it is to their efforts, and the success attending them, that our draughtsmen and students must needs look for encouragement.

Mr. Curlett is a member of the American Institute of Architects and indorses fully all their efforts for the advancement of young members of the profession.

WILLIAM CURLETT.

Letter Gilding.

LETTERS written on vellum or paper are gilded in three ways. In the first a little size is mixed with the ink, and the letters are written as usual. When they are dry, a slight degree of stickiness is produced by breathing on them, upon which the gold-leaf is immediately applied, and by a little pressure may be made to adhere with sufficient firmness. In the second method, some white lead or chalk is ground up with strong size, and the letters are made with this by means of a brush; when the mixture is almost dry, the gold-leaf may be laid on and afterward burnished. The edges of the leaves of books are gilded, while in the binder's press, by first applying a composition formed of four parts of Armenian bole and one of sugar-candy, ground together to a proper consistency, and laying it on by a brush with the white of an egg. This coating, when nearly dry, is smoothed by the burnisher; it is then moistened, with clear water, and the gold-leaf applied and afterward burnished. In order to impress the gilt figures on the leather covers of books, the leather is first dusted over with very fine powdered resin or mastic, then the iron tool by which the figure is made is moderately heated and pressed down upon a piece of gold-leaf, which slightly adheres to it, being then immediately applied to the surface of the leather with a certain force; the tool at the same time makes an impression, and melts the mastic which lies between the heated iron and the leather. In consequence of this, the gold with which the face of the tool is covered is made to adhere to the leather, so that on removing the tool a gilded impression of it remains behind.—*Manufacturer and Builder.*



First Floor Plan of $5,500 Country Dwelling. See "Our Illustrations."

To Prevent Vermilion Darkening.

Pure vermilion will, in the course of a few months, if exposed to the sun and atmosphere, turn into a dirty brown color. Adulterated or mock vermilion will do the same, but far more rapidly. A remedy for this has long been sought. It is said that if flour sulphur is added to the paint whilst mixing, in the proportion of one-eighth, the vermilion will retain its brilliant color for a considerably longer period than without it.

Liquid Glue.—The *Muster Zeitung* recommends, in preference to the treatment of glue with nitric acid, the following: So-called gelatine is dissolved in the water bath in its own weight of strong vinegar, a quarter part of alcohol, and a very little alum. This glue remains liquid when cold, and is much used for cementing mother of pearl, horn, etc., upon wood or metal.

Bound volumes now ready. Price, $2.50 each.

INSTITUTE OF BRITISH ARC
MDCCCXXXIV

Our Illustrations.

In this issue we present an engraving of four of the prominent architects identified with the San Francisco Chapter. It is our intention to give a few each month, until we have secured a written history and likeness of those that labor so earnestly for the advancement of the study of architecture.

The design presented on page 13 is suitable for a country or suburban home. We present two arrangements—one with eleven rooms and bath, the other nine rooms and bath. In either case, the arrangement is very desirable for a country home. The difference in cost between the two plans will be about $500. As shown, this design, carried out in its entirety, will cost about $5,500.

The design on page 5 is from our regular correspondent; the explanation accompanying the same is very full, and will prove interesting reading.

On page 17 we present a sketch from our artist, John Wolf, of New York. We trust in the future to be able to give many sketches from this gentleman.

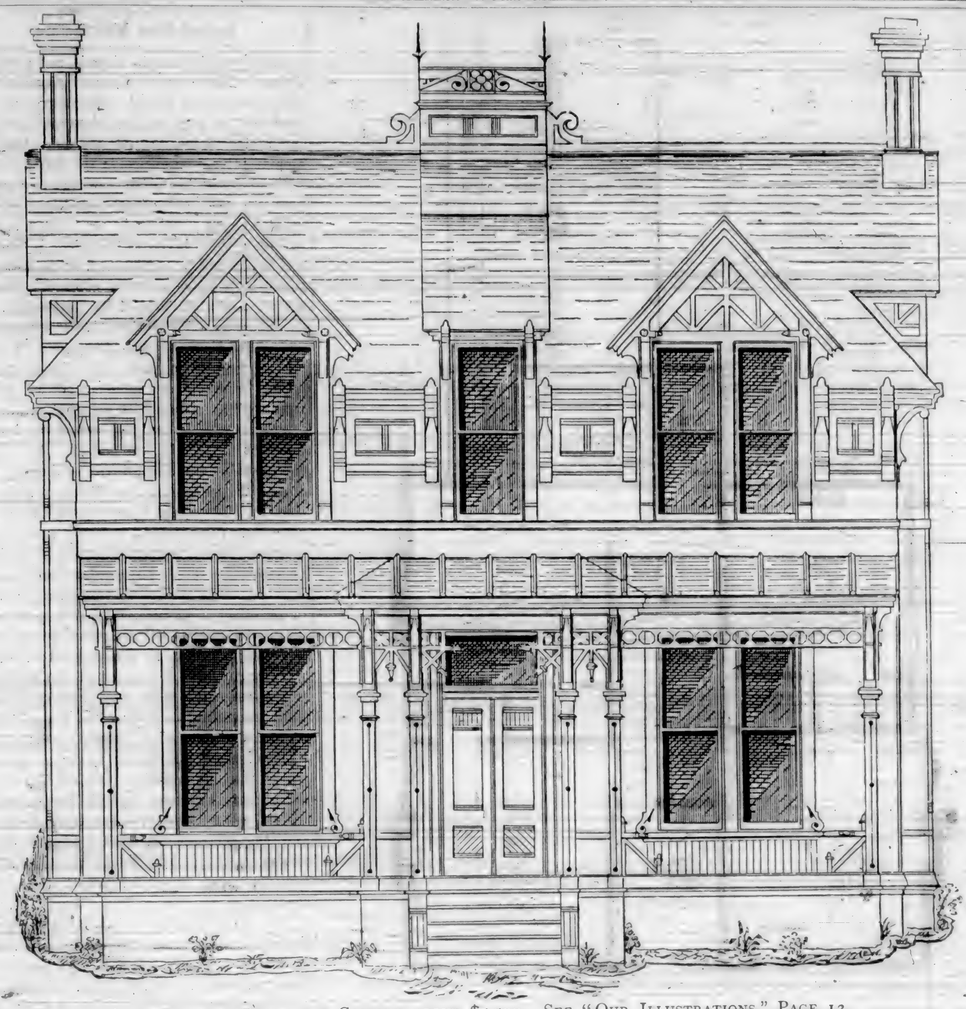
On page 18 will be found an original design for a cresting.

Drying Lumber.

Small quantities of timber may be quickly and thoroughly seasoned by steaming. The philosophy of this process—which, if properly performed, does not injure the strength or durability of the timber—is very simple. A very large percentage of the sap in all kinds of wood is water. This water, heated to boiling, expands sixteen hundred and fifty times. It follows that if wood be heated to 212°, the boiling point of water, the capillary cells can contain only one sixteen hundred and fiftieth as much water as at ordinary temperature, the expanded water escaping as steam. The proportion of moisture left in the wood is, after steaming, less than that demanded by its ordinary hygroscopic condition. At least it is found to be so for certain species of hickory and white ash, which increased in weight after being removed from the steamer and the surfaces had become dry.

The steaming should be done gradually—that is, time should be given for the wood to gradually rise in temperature, and so that the sap may escape gradually from the cells without rupturing them by its expansive force when converting them into steam. The steam should be generated in a suitable boiler and allowed to escape at two or three pounds pressure, which should be gradually reached in proportion to the size of the pieces which it is desired to season.—*The Lumber World.*

Every material man in the United States should at once subscribe to this journal. By so doing, you will obtain a list of parties making building improvements, and thus be enabled to send your circulars to those to whom it will be of the most benefit.



A Country Residence Costing about $5,500. See "Our Illustrations," Page 12.

Carpentry in Olden Times.

In early English times very little that resembles modern joinery existed, every part being rude and united in an artless manner. The first accurate and neat workmanship was in the stalls, pulpits, and screens of cathedrals and churches, and the furniture of the abbeys, but this was of the most simple kind. As time went on there was more neatness, soundness, and accuracy in work. When plain surfaces of considerable width and length were introduced, as in wainscoating, the surfaces were commonly formed of inch, or inch and a quarter boards, joined with glue, and a cross or feather tongue ploughed into each joint. When the boards were glued together and had become dry, tapering pieces of wood, called keys, were grooved in across the back with a dovetailed groove, the keys preserving the surface straight and also allowing it to shrink and expand with the changes of the weather. In fixing landings of stairs, tops of tables, etc., sometimes a wide board, or a piece consisting of several boards, was fixed by means of buttons *screwed* to the back, which turned into grooves in the framing, bearers, or joists, to which it was fixed. If any shrinking took place, the buttons slid in the grooves. In forming architraves, the simple method of ploughing and tonguing work together was followed, providing effectually against the greatest defect of timber work, its shrinkage. By this method, the bold mouldings of Gothic architecture were executed with a comparatively small amount of material. In laying floors, the tongue was ploughed into each joint. Ordinarily the boards were only tacked down the first year, and nailed down for good next year, allowing of correcting any tendency to rise, or the opening of joints. In most old structures the floor is laid with remarkable evenness and accuracy, the boards being soundly fixed to the joists. In oak floors the ends were forked together. In hanging doors, centres were often used instead of hinges. Of the various kinds of hinges, some were concealed, but most projected, the door folding back over projecting mouldings. In stairs the rise or tread of the steps is found to be very moderate. Winding stairs were seldom introduced, being chiefly rectangular, with ornamental railing and newels. In some staircases, two rows of steps of different level are met with double tread.—*Building.*

OIL ON WOODWORK.—Carefully conducted experiments have demonstrated the fact that seasoned wood, well saturated with oil when put together, will not shrink in the dryest weather. Wheels have been known to run many years, even to wearing out the tires. Very many dollars might be saved annually if this practice were adopted. Boiled linseed oil is the best for general use, although it is now known that crude petroleum, on even old wheels, is of great benefit.

Bound volumes now ready. Price, $2.50 each.

MAKING WALNUT STAIN.—One quart water 1½ oz. washing soda, 2½ oz. Vandyke brown, ¼ oz. bichromate of potash. Boil for ten minutes, and apply with a brush either hot or cold. Permanganate of potash dissolved in water gives also a good brown stain.—*Exchange.*

Cockroaches will not molest the binding of a book which has been varnished with a mixture of two parts copal varnish to one of turpentine.

Bound volumes now ready. Price, $2.50 each.

Stained-Glass Manufacture.

THE art of glass-staining is not a new industry. There are two descriptions of glass made use of, one called "pot-metal," which is produced by melting the glass and the coloring matter together, the pigment thus permeating the glass entirely; the other is called "flashed-glass," to produce which two melting pots are used, one of pot-metal, the other of colorless-glass. When in a proper state of fusion, a thick layer of the latter is laid out, and is covered by a thin film of the former, so that the surface only is colored. This description of glass is used for embossing. For the purpose of painting, both colored and white glass is used, and the pigments, generally of metallic oxides, finely powdered and mixed with oil of spike or other volatile medium, are laid on with a brush.

The art of glass-staining is practiced in four different ways, viz., the mosaic, the enamel, the mosaic-enamel, and the embossed. The mosaic is the ancient method, in which each color in the picture is represented by a separate piece of glass, and is fixed in its place by means of leaden frames, a mode which did not necessarily preclude any gradations of shading. The enamel is the application of pigments, as in painting a picture, by which process the nicest delicacy of shading can be produced, but what it gains in this respect it loses in transparency and brilliancy of tint, and hence is less esteemed than the pot-metal mosaic work; nevertheless pictures of a much higher artistic character can be produced; and, although less esteemed, it is more generally employed than the mosaic, indeed, it is now usual to combine the two methods in the mosaic-eminel, wherein the brilliant tints of the one, and the picturesque, although more opaque, effects of the other, produce together a more complete and beautiful result than either separate.

The colors employed in glass-staining are produced from various sources. Gold, in the state called purple cassius, or as a simple solution without tin, gives ruby, crimson, and purple. Iron, as a protoxide, a dull green; combined with alumina, flesh-tints; with chloride of silver, orange, and as a protoxide, a brownish red. Copper, as a sub-oxide, a rich ruby; and as a black oxide, a brilliant green. Uranium, a chrysoprase green and canary, slightly opalescent; cobalt, blues in every variety; carbon in the form of charcoal or soot, a common yellow; arsenia or arsenic acid, opaque white; magnesia, as an oxide, amethystone purple, and as a peroxide with cobalt, garnet red; silver, with alumina, a brilliant yellow; with others, as dictated by the experience of the workmen. The beautiful yellow of ancient glass could not, until recently, be produced by modern glass-workers.—*Building.*

This is the first month of the New Year, and is just the time to subscribe to a journal of the character of the "California Architect." Two dollars per year.

Egyptian Mechanical Methods.

PETRIE, who is the author of a treatise on ancient metrology, has lately turned his attention to ancient Egyptian processes. Though much labor has been bestowed on the literary remains of Egypt and the description of monuments, little attention has been given to finding out the tools and methods by which their results were reached. The first conclusion to which Mr. Petrie comes is that the stone cutting was performed by means of graving points far harder than the material to be cut. These points were bedded in a basis of bronze; and in boring, the cutting action was not by grinding with a powder, as in a lapidary's wheel, but by graving with a fixed point, as in a planing machine. From discovering spiral grooves in diorite and granite, at least one-hundredth of an inch in depth, the author supposes that an instrument was used of sufficient hardness to penetrate the material that far at a single turn. In this, however, he was corrected by Mr. Evans. The simplest tool used was a straight bronze saw set with jewels; but there is proof of one circular saw which must have been six and one-half inches in diameter. For hollowing the insides of stone objects, the inventive genius of the fourth dynasty exactly anticipated modern devices by adopting tubular drills varying from twenty-four-hundredths of an inch in diameter and two-hundredths of an inch in thickness to 18 inches in diameter. Other drills, not tubular, were used for small holes, one measuring one and two-tenths inches long and eight-hundredths of an inch in diameter. But this is surpassed by the Uaupes of South America, who drill holes in rock crystal by the rotation of a pointed leaf shoot of plantain, worked with sand and water. The writer of this note has seen, in Porto Rico, stone beads of the hardest material, 2 inches long, bored longitudinally with an orifice one-sixteenth of an inch in diameter. The Egyptians understood rotating both the tool and the work. For the finishing of vases, a hook tool must have been used; but the early Egyptians were familiar not only with lathes and jewel turning tools, but with mechanical tool rests, and sweeping regular arcs in cutting. In addition to the tools mentioned, are to be noticed those for dressing out drilled cores, stone hammering and smoothing, saws with curved blades, mallets, chisels, adzes, and bow drills. For marking and indicating the plane of the stone, red ocher paint was used in a variety of ways, well studied out by Mr. Petrie. Rock excavation, both for saving the stone and for the creation of vaults and chambers, was altogether an affair of drilling. Granite bowlders were utilized in the pyramids, but the best stones were taken from quarries. The method of handling these immense masses is not known. Mr. Petrie concludes with a sensible remark upon the oft alleged inhumanity of the pyramid and temple builders. To require a man every six years to serve upon the public works, during the season when he could do nothing else, would certainly not be a great hardship.—*Science, from Journ. Anthrop. Inst.*, xiii., 88.

Varnishing of Wood Work.

THE number is yearly diminishing of those who believe that exterior causes exert no bad influence on varnishes, but there still remains too large a showing of those who blindly claim that, "if the varnish is all right, and the painter understands his trade thoroughly, there is no necessity of all this painstaking in the construction and heating of the finishing rooms." It would be as reasonable to claim that heat, cold, and moisture have no effect on the thermometer and barometer, as that oil, turpentine, and compounds, into which they largely enter, as proof against atmospheric changes. Turpentine will absorb moisture, and linseed oil is affected by both heat and cold, heat rendering it thinner, and varying degrees of cold causing it to thicken, until at length, at about zero, or a few degrees below zero, it congeals. As components of varnish those liquids are not quite so sensitive to heat, cold, and moisture as when in the simple state, yet are sufficiently susceptible to cause trouble and serious loss to the builder who fails to provide against their insidious workings. Those railway car painters who are compelled to finish their work in indifferently heated sheds, assert that it takes about double the quantity of varnish to do over the outside of a car, solely on account of the chilling of the varnish—in other words, the thickening of the oil contained in the varnish. The surface of the car, of course, contributes its share of cold, proving conclusively that the combined effects of the atmosphere and the chill on the surface of the car, are adverse to economy in the use of stock, to say nothing of the liability to enameling, minute cracking, and pitting, with the unprofitable and vexatious labor they entail.—*Ex.*

Promptness in renewal of subscriptions will enable us to still further increase the number of improvements necessary to make this journal fully equal to those printed in the older cities.

Painting Iron.

THE value of red lead as a preservative for iron has been generally accepted. Wrought iron requires a hard and elastic paint, which will hold itself together even if the scale beneath gives way. The following experiments, made under the auspices of the Dutch State railroads, may be instructive. Iron plates were prepared for painting as follows: Sixteen plates, pickled in acid (hydrochloric), then neutralized with lime (slaked), rinsed in hot water, and while warm rubbed with oil. The same number of plates were cleared of scale, so far as it could be removed by brushing and scraping. Four plates from each set were then painted alike—namely, four plates with coal tar and four plates with iron oxide A, another set with iron oxide B, and the remaining set with red lead. They were then exposed three years, and the results observed were as follows: The coal tar on the scrubbed plates was quite gone, that put on the pickled plates was inferior to the others. The iron oxide A on the scrubbed plates was inferior to the other two, while on the pickled plate it held well. The oxide B was found superior to that of A, but inferior to red lead, while the plates covered with red lead stood equally well on both prepared plates, and were superior to all others. From these results it is evident that pickling the iron removes all the black oxide, while scrubbing does not. It is also shown that the red lead unites with oil to form a hard, oxy-linseed oil acid soap, a harder soap than that given by any other combination. The red lead is shown by those experiments not to give way under the scaling; it is more adherent to the surface, more elastic and cohesive. On the Cincinnati Southern Railroad, experience extending over some years has shown that red lead has proved the most durable paint in the many miles of iron trestle and bridgework. It is found that the iron oxide is washed away by the rain and perishes in spots, although a valuable paint if frequently renewed. Red lead, on the other hand, is more expensive than iron oxide and is difficult to be obtained pure. It is adulterated with brickdust, colcothar, and other substances, and has lost its high repute.

Referring to white lead as a material for painting iron, one authority observes that "white lead should not, if possible, be used in priming iron, nor in any priming coat; moreover, it is a less desirable overcoat than iron oxide. The class of iron paints compounded of ores of natural iron rust, combined with clay or some other form of silica, are very useful, as they contain no water nor sulphuric acid. Magnetic oxide, or pure iron oxide, is an excellent protection for iron, says one writer; it is impossible to scrape it off. It is also of value in woodwork, and resists the action of salt water and sulphurous gases, so destructive to most paints. There is no doubt the great protective element in paint is the oil, and the conditions required for success are stated to be to prevent the drying part of the oil from becoming hard dry; the soft-keeping, non-drying acids must be kept from flying away in such a quantity as to reduce the oil to a brittle mass. In other words, the elastic qualities of the oil must be protected from the action of the oxygen.—*Scientific American.*

The Gimlet.

A MOST insidious dog—
"A great bore withal, and yet of no great calibre."

The gimlet is an offspring of the awl, and is of comparatively modern origin. Traces of the dual use of the latter as both gimlet and awl are discoverable in Egypt as early as the nineteenth centurybefore Christ, and no development of the gimlet as a separate tool was made by that people so far as is known. At the opening of the Greek era the gimlet was known to that people simply as an awl with an egg-shaped handle. With the Greeks it first took its place as a distinctive tool, and later became very common. Its first inventor is unknown, as is also the date of the invention. Pliny ascribes it to Dædalus; but whatever Pliny did not know he deemed it a point of personal and professional honor to make up, and little credit is to be given to this fable. The gimlet of the Greeks had the cross-head, or handle of the style now prevalent. It also had possibly a hollow pod, as the earliest specimens found are of that type, but it had no screw point and demanded a large expenditure of muscle, especially in boring hardwoods, where it was not very effective. Later a gimlet of square section, having sharp corners and tapering to a sharp point, was introduced and gave the hint for a form of auger now in use. In course of time the screw point was added, and the hollow-pod gimlet, with a point of this kind, was the only kind in use for many centuries. In England this was called a wimble. This form is still in use to some extent, and is effective where very shallow holes only are to be bored, but as it has to be removed whenever the pod becomes full of chips from boring, it causes a waste of time when deeper holes are desired. The twisted or spiral form of gimlet, which is self-discharging, is an American invention and only of very recent date. It has, however, superseded all other forms, and is now in common use. The field of the gimlet is becoming greatly narrowed, giving ground to the more rapid and convenient brace and bit.—*Call Smith, in Industrial World.*

CHENONCEAUX: FRANCE.

THE above sketch is by our artist, Mr. John Wolf, of New York. We are making preparations by which we will shortly be enabled to present sketches from local artists, as well as those in Eastern cities.

Door Decoration.

THE door, which is so frequently a source of anxiety to the ornamentist and decorator, might be made the means of greatly enhancing the artistic completeness of a room. Much of the difficulty experienced in its treatment arises from the desire to disguise its functions. For this reason doors having their panels covered—I cannot say decorated—with wall-papers, &c., no matter how beautiful or costly, fail to please, and the palpable effort at disguise is not only bad but reprehensible, and whenever the position or purpose of a door is thus sought to be hidden, the result is a failure.

In modern-built houses the architects are devoting more care and thought to the design and proportion, and the cabinet-maker to the construction than hitherto, and it is now, fortunately, not uncommon to find doors so original, thoughtfully proportioned, and broken up into panels that they are in themselves perfect, and, as a piece of decorative work, charming. An attempt to still further decorate such doors as these would be unpardonable, and a piece of vanity on the part of the artist; but on the other hand, there are thousands of houses—many of a superior kind, if we take the rental as a criterion—the rooms of which are positively disfigured by doors out of all proportion to their position, many being too short and wide, too high and narrow, or in an intermediate state, which is more aggravating than either, effectually preventing a successful treatment of the room as a whole. Such doors form a stumbling-block and eyesore to many otherwise comprehensive schemes of decoration. The embellishment becoming a necessity, the difficulty is—what to do? It may be only necessary to decorate it slightly to harmonize it with the rest of the room, or it may require much more substantial and heavy treatment, both in ornament and color; the surroundings will, of necessity, determine this point. A most satisfactory and effective treatment is to be obtained by outlining the design in warm browns, allowing the figure of the wood to show through, but the door must be a new one, and capable of such treatment; if, on the contrary, as is far more likely, it be an old and badly painted door, then some such treatment as I have shown in my illustration would prove effective. The dimensions of the panels were taken from an existing door divided into four, those shown being the upper ones. This door being disproportionate, and the panels consequently so, it has been sought to make it appear wider by running the flower-spray behind the center stile into the other panel;* had the panels been too wide, a contrary treatment would have been followed. The desire to elongate panels may be realized by each having a separate design of some upward growth, and, if found necessary, marginal lines to still further help the illusion.

We might advantageously make our doors an object of interest by using them as an opportunity for displaying decorative ornaments. In such positions there is more latitude allowed, and a greater freedom to the artistic fancy; thus, representations of the figure, birds, animals, &c., are here permissible, all of which are out of place and unfit for the walls of our dwelling-rooms, owing to the necessary repetition becoming objectionable and devoid of beauty, and to the accessories hiding and mutilating their parts.

The subjects for such panels should bear the impress of having been designed to fit the place they occupy, and for no other purpose. There is plenty of scope for our selection, the panels of doors offering not only a valuable and legitimate means for the display of the wood-carver's art, but for porcelain-painting inlay, hand-painted or stencilled ornament, needlework, painted silk or tapestry, the latter being sometimes particularly pleasing and effective.—*Geo. C. Haite, in the Builder.*

*This may be accepted as a motive for the treatment referred to in special cases; but, in general, we object to running the design through from one panel to another, as contradicting the actual construction of the door, and making the panels appear as one piece overlaid by the stiles.—ED.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

DESIGN FOR CRESTING.

Copyrighted by WOLFE & SON, architects, January 15, 1884.

Evils of Letting Plumbing Contracts to Builders.

ONE great obstacle to securing plumbing work in accordance with modern standards in Cincinnati is the builder's influence. It is a community that still retains the pernicious custom of letting plumbing contracts to builders instead of having it done by days' work, or by a contract direct with the plumber. A good illustration of the result of this practice was recently brought to our attention. In a store on Walnut Street near Fourth, one of the most prominent locations in the city, we saw a builders' substitute for a properly constructed water-closet. In a closet inside the building was the usual privy seat, beneath which was a vault about six feet deep by four feet square. This was apparently cemented, and from this receptacle there was a drain, the entrance to which was closed by a plug, which plug could be removed when occasion demanded. The closet in which this privy was placed was in a one-story extension, on the roof of which was another privy house for the accommodation of the occupants of neighboring buildings, and this communicated with the same vault, the droppings from above passing behind a partition that ran from the seat to the ceiling of the lower closet. As the door from this lower closet opened directly into the store, the fragrance of the locality may be imagined. The lessees of the store did not enjoy stinks, and demanded that the landlord should provide a different arrangement. It should be stated that the builder had carried a rain-water leader through the side wall, in order that the accumulated filth might be diluted during rain-storms. The owner of the property, we learn, has since employed a plumber to provide suitable water-closet accommodations properly connected with the drain to the sewer, and there is no evidence that either the owner or the builder adopted this stench-generating device to save money, but simply because the former left the matter to the builder, who followed an ancient custom, assuming it to be good enough.

The mere fact that an owner is sufficiently indifferent to be willing to regard this important work as on a par with the other details of house construction, is conclusive evidence to the plumber that price is the main consideration, and if he satisfies the builder, who is his principal in the transaction, he has done his duty, though the builder's standard is rarely a high one. Errors or omissions in the specifications, a common occurrence, are not pointed out, since if a plumber is officious in this respect the builder is displeased, and in subsequent work avoids employing such a "particular man." "Carry out the specifications, and mind your own business," must be the motto if you work for builders.

Our experience has taught us that wherever this practice prevails, competition, cut-throat prices, and poor work are the rule.

In order to change this condition of things, a public sentiment must be created that will induce the owner to take a personal interest in the work, and make contracts only with the plumber; and to hasten this result the leading plumbers in a place should agree with each other to refuse to be sub-contractors, even if they make a temporary sacrifice. When owners learn that only second-rate men will serve as sub-contractors, they will quickly settle the question, with the result that they will be better served, the plumber's position properly appreciated, and his services more liberally paid for.—*The Sanitary Engineer*

WET BOOTS AND BAD COLDS.—Taking a chill after getting the feet wet is one of the most fruitful causes of disease. The wet months are now coming on, and how best to keep the feet dry must be of universal interest. In two ounces of unpurified castor oil, melt a quarter of an ounce of beeswax and two ounces of fresh mutton suet. When nearly cold, but before getting stiff, rub thoroughly with the hands all over the outside of the boots—soles as well—leaving a good coat on for the space of three days, after which all that can be removed may be scraped off. To be thoroughly effective the boots should be sponged the previous day with lukewarm water so as to entirely get rid of the blacking. The boots will of course not take a shine just after the operation, but they will be found to keep out the wet and to last a great deal longer than if not thus treated.

Bound volumes now ready. P $2.50 each.

Waste of Redwood in the Coast Range.

THE wastefulness of lumbering is one of the striking features of the scene. Only the largest trees are cut, those measuring less than two feet in diameter rarely being touched, and the ax is laid, not to the roots (though they are not thick and widely divergent, considering the height and weight they support), but some distance above, so that in very large specimens the massive stump, upon whose flat top you might build a comfortable house, stands twelve feet above the ground, and contains hundreds of feet of sound lumber which must be left to burn. Then many trees are broken by their fall so that large parts of them are useless; other parts may be knotty, or crooked, or inconvenient to drag out, and so only half of a great trunk will be utilized. Huge logs are consumed, also, in road-making and bridge-building in the hills, and dozens of small trees are crushed by the fall of their greater companions. Then, when a district is pretty well cleared of its best timber, fire is set in the brush and prostrate trunks. Feeding eagerly upon the resinous woods, half dried and broken, it gathers so much heat that the saplings are nearly killed, and the flaky, tinder-like bark of the larger trees is singed in a way which must greatly injure and often destroy them. Moreover, these fires, fanned by the gusty breezes, rushing in every afternoon from the ocean, often get beyond control, and sweeping through the oily tops and brittle trunks, spread blackened ruin over miles and miles of precious forest. *Precious*, however, it seems never to occur to the lumberman these forests are; yet he is probably no more wasteful and careless here than elsewhere, and finds his match for heedless extravagance in nearly every pursuit that deals in what nature furnished us at the outset in abundance, but replaces only very slowly, giving abundant leisure for our repentance. The spendthrift lumberman is bad enough, but no worse than the wasteful oysterman or buffalo-hunter, reckless of the future. It is, or ought to be, a matter of rejoicing to everybody that the forestry people, under Mr. Sargent's guidance, are paying especial attention to preserving as far as possible the magnificent forests of the Coast Range.

WHAT IS AN ACCOUNT BOOK QUIRE?—The word "quire," in account books, is a misnomer, and is used simply as a matter of convenience (probably a "trick of the trade"). As explained by manufacturers, a quire of paper is twenty-four sheets of good and bad or imperfect paper. They reject the bad, and still call the remainder a quire. It is difficult, however, to make the purchaser believe that any quire with the roughest of usage can be reduced to twelve or fifteen sheets and still be a quire of paper. The price per quire is the recognized governing quality, but many account book manufacturers appear to put more or less sheets to the quire as their conscience and the price will permit. Account books should be sold at per hundred pages, and then purchasers would know exactly what they had got for their money.

American Plumbers and Contract Work.*

IN speaking this evening on the abuses existing in the plumbing business, it will greatly help us to go back thirty-five years, when plumbing, compared with to-day, was in a crude state, and trace the history of the trade during that time down to the present day. The men engaged in the plumbing business thirty-five years ago in this city, came from the Eastern cities and Europe, and were strangers to the methods then in use here, there being no sewerage system,—wooden water pipes, with which it was difficult to connect, and other obstacles which have long ago disappeared. All these difficulties were overcome by the plumbers in those days, who were masters of their trade. By hard work, energy, and perseverance, they became successful financially, and were respected and honored in the community. The fact of their being plumbers proved no bar to their mingling with the best classes of their time; no odium was attached to them—no reflections cast upon them. The business was not only considered a useful and necessary one, but a most important branch of industry. They planned the work, furnished the material, and, having the confidence of the men who employed them, good work was always the result. There was no dickering about price—no fault-finding with charges made. The mechanic and owner did business together, in a business way; each having the confidence and respect of the other, they were naturally friends. These were the Garden of Eden days of plumbing in this city.

This tranquillity was too good to last, and in time an evil spirit made its appearance in the shape of the plan-makers and skin-builders. These men undertook to build elegant buildings at greatly reduced prices, and Mr. Goodfellow and Mr. Goldlover were both enticed into the net prepared for them. A plan was made, and Mr. Plan-maker called around to the shop of Mr. Good-Mechanic, and whispered into his ear: "I have planned an elegant residence for Mr. Goldlover. He has purchased land fronting a beautiful street. I want you to get the work. I know you have means, and have heard of your mechanical skill. Give me an estimate on the work; I will give you the preference, and Mr. Goldlover will employ you in the future to do all his work. Now figure very low, as I expect to get other figures on the job." Mr. Good-Mechanic listened with attentive ear and said: "Figure on a job, or figure on a plan? Why, my dear sir, I never figured on a job in my life. I know not how to figure on your plans. Your specifications read strangely to me; they are impractical. Yet, if I can gain your friendship, and that of Mr. Goldlover, I shall try and do the best I can." The apple is plucked, the fruit is eaten, and the unsuspecting good mechanic has committed a sin that has existed ever since.

What are the results of this rash act of our parent plumber? You all know the result of the contracting system then established. The war of hatred then began—one plumber cutting the throat of the other, one running down the fair name and reputation of the other, until the public heard of the quarrel, and they took up the cry and began calling the plumbers such beautiful names as "thieves" and "extortionists," and applied other epithets which would bring disgrace upon them. The funny press, the illiterate laborer, the wealthy Goldlover and friendly Goodfellow howled at the once prosperous Good-Mechanic, and he slipped down from the position he formerly enjoyed to that akin to the commonest laborer, which he has held ever since. Now, why should we endure this? Are we not as good as men engaged in other pursuits? What we must do is to recover from the impositions which are heaped upon us. In order to do this we must do away with the contract system, for the reason that it is unjust to us—do away with the skin-builder, who has in construction a number of houses, and the plan-maker, who lays out the work for us to follow, no matter how impractical. We have to compete with unskilled labor, as Mr. Skin-builder's object is only to have it last until he can sell the building. And we get all the blame from parties who were inveigled to buying a house which Mr. Skin-builder and Mr. Plan-maker never intended to be fit to live in. If the owner is willing to pay a good price, under the contract system the competition is the same, making no distinction between a good or a poor mechanic. It is a libel on the plumbers of this city and of the country at large to hold them responsible for the misdeeds committed by cheap owners and cheap builders. Then, again, under our license system, any man who can furnish a bondsman can get a license to carry on this very important branch of the mechanical trades. Neither his habits, his mechanical skill, nor his ability to perform any part of the plumbing is scrutinized. In the cities in the East, which have a settled foundation of business, like New York, Philadelphia, Washington, and Baltimore, the contract system has practically disappeared. Plumbers whose reputation is co-extensive with the boundaries of this great country, do all their work by the day, and furnish all the materials for jobs which run up to $50,000 and $70,000. While I was East I saw a job which amounted to $75,000, which was done by the day, and was told this was only one of many instances.

Knowing how unjust the system of taking work by contract is, is it not time, then, to do something to abolish it? Again, the question arises, Is there any money in contract jobs? Has experience shown that any one in the business has been able on contract work to hold his own? Here, gentlemen, is what experience teaches, and I believe by a close scrutiny of the figures I now give you will not find them to be very far from right. Take the case of a plumber who does $50,000 worth of contract work a year. This work is figured on the basis of 10 per cent. profit on the material and labor. The cost of running a business of this extent is as follows: A foreman, $1,200; rent, $800; book-keeper, $600; horses, wagons, and driver, $900; gas and water, $25.00; loss and insurance, $250; your own time, $1,200; making a total of $4,775, leaving a profit of $225. These are facts and figures which cannot be disputed. The ruinous system of competing for contract work has crippled every wealthy man in our trade, with one exception, and he was saved from financial ruin by going into an early grave. This being the case, it seems to me high time to let that class of work alone, and if we go about this in earnest, the change is effected. Then, again, how many of us do $50,000 worth of work per annum? Not many, I can assure you. A man who has worked faithfully and honestly at the plumbing business in this city for nearly a quarter of a century—a man you all know, a man who is strictly temperate in habits and keeps strict account of everything appertaining to his business—will make affidavit to the fact that he has lost in contract work $15,000 in three years. The money thus lost was the accumulation of former years' prosperity. Again, we work like slaves from early morning till late at night. Look at our faces during these hours—the thoughtful expression, the languid look. No smiling face is there to see.

These thoughts of mine, gentlemen, I desire you to take home to-night, reflect on them, seriously think of them, and ask yourselves, Shall I any longer be deluded into working and slaving for the benefit of an unthankful builder? Remedy these evils, then, by forming yourselves into a strong organization, and in a short time I predict that instead of receiving no remuneration for your services, you will be blessed by an abundance for the labor then performed.

* A paper read by Mr. J. J. Wade before the Chicago Master Plumbers' Association.

How to Measure the Contents of a Round Tank.

NEW YORK, November 21, 1883.

To the Editor of the Hydraulic and Sanitary Plumber:—

SIR: In the last issue of your paper you gave a simple rule for the measurement of a round tank, which, for all practical purposes, is perhaps near enough to be sufficiently correct for practice. It is not so, however, in a strictly mathematical sense, and this I will illustrate.

To find the contents of a copper boiler according to the rule given, we will suppose the height to be 5 feet and the diameter 14 inches.

One-half diameter = 7
One-half circumferance = 22
Height, 5 feet = 60

Multiply all these together, and the result will give 9,240 cubic inches. Dividing this by 231, the number of cubic inches in a United States gallon, we have 40 gallons as the contents of the tank. This rule is, as you say, simple, but it may be still more simplified by stating that an easy way of getting approximately the circumferance of the boiler is to multiply the diameter by three and one-seventh.

Friction of Water Pipes.

THE flowing of water through pipes of different diameters is affected to a great extent by the head or pressure—the relative smoothness—the curvatures and shortness or abruptness of the angles of the conduit. This is what is denominated friction, and is a very important consideration in the distribution of water, not alone in aqueducts but also in house supply for domestic purposes. It is with the latter we propose briefly to deal, in so far as it relates to proper sizes and the objects for which it is intended. In most cities of the Union there is a standard fitting for almost all kinds of houses, and this is determined by what is required for a reasonable demand consistently with the amount on hand for distribution. In New York the tap or fitting for this purpose is almost universally five-eighths of an inch in diameter, and is simply a brass cock driven in a hole tapped for the purpose, having a soldering coupling attached for the purpose of being united with the lead pipe. In years past it was the custom of plumbers to connect with this tap the same sized pipes, and as the head of water was greater and the amount and character of fixtures to be supplied not so numerous or exigent, no great complaint was made of insufficiency. In course of time, however, the growing demand for loftier buildings, and also the lessening pressure owing to increased consumption, produced much disatisfaction among our citizens. Efforts then commenced to be made to get, if possible, more water from the mains, and it is certainly curious to note the various devices by which the supply could be increased, while the size of the tap still remained unaltered. It was not uncommon to see, in some cases, a piece of four-inch heavy lead pipe, five or six feet long, put in close to the tap. This was to act as a reservoir to hold a certain amount of water, but no one understanding it could think it a very efficient means. The device of boring in two mains connected with the tap by branching in the coupling at the bend or bow of the pipe, was frequently adopted—one of the mains to be used in the lower part of the house and one for the upper, while in both of those cases the pipe remained the size of the tap. In a few rare cases, when driven to desperation, some house-holder had extra taps surreptitiously put in, so as to get a supply commensurate with these demands. Finally, the expedient of enlarging the size of the pipe from the tap occurred to plumbers, and it certainly was a revelation to many of them. The quantity became magically increased, and for many years afterward no complaint could be heard. It surprised many that so much more water could be obtained than in the old way; and yet the cause was quite simple, as by lessening the friction the volume of water was proportionally increased. We have been at the pains of making some short calculations to see why this should be so, and to what extent the flow is retarded or accelerated by friction on two well-known and commonly used sizes of pipes, one inch and five-eighths of an inch. If we take the length of a five-eighth pipe—which will contain one gallon of water—we find it will measure sixty-two feet nine inches in length. The same quantity of water in a one-inch pipe will require but twenty-four feet six inches. The interior surface of the five-eighth-inch pipe has an area of 1.618 square inches, or nearly 11¼ feet, while the surface of the one-inch has an area of 924 inches, or nearly 6½ feet. We see, therefore, that in these two sizes the friction is as 11¼ to 6½, or nearly one-half, and which, taking into account the superior rigidity of the larger pipe and its likelihood of having fewer bends in it, would deliver probably more than double the quantity of water. The larger sized one and a quarter, one and a half or two-inch would still more increase the effect desired proportionally. It is found by experience that a five-eighth pipe extended 3,000 feet horizontally under a head of 24 feet or 10 pounds pressure to the square inch will cease to deliver water at its extremity, thus showing that friction uses up the capacity of the water to flow any further. This would seem to be a strong argument against using the smaller sizes of pipes at a distance from the main. We have often thought that much of the difficulty of obtaining water at points remote from the mains could be overcome by using larger pipes, or not diminishing them at all. It might certainly add to the cost of plumbing a building, but where efficiency is a *sine qua non* something must be sacrificed to the main object—a regular and undiminished supply. Moreover, to equalize the distribution through a building instead of, as in the present fashion, decreasing the pipes at the extremities, at the rears or the upper stories, every floor or every fixture should have a separate stop-cock which could be closed, or throttled, as it were, to adjust the supply as equally as possible at every point, whether high or low, all through the building, and these should be carefully regulated to produce a uniform supply. I have an idea that the piping of a house on this plan would remove much of the dissatisfaction manifested by house-holders at the inequality of distribution of water, and at this particular time, when we are suffering so much from scarcity of this great necessity, could hardly fail of commanding the most unqualified approval.—*N. Y. P., in the Hydraulic and Sanitary Plumber.*

Street Car Starters.

A GREAT deal of ingenuity has been expended on the invention of street car starters. A man of humane tendencies watches the horses tugging and straining to get a car started, and he naturally thinks it would be a relief for the horses and a fortune to the inventor who could devise an appliance which would absorb the work done in stopping a car and give it out in starting. The more this philanthropist thinks of the car starter, the more convinced he becomes that he is in the way of preventing cruelty to horses, and of laying the foundation of his own fortune. It does not take long to plan a spring arrangement which can be wound up by the moving car which it tends to stop. Then he gets the device through the patent office, but in the meantime the discovery is made that a multitude of inventors have already been in this field. However, inventors are a hopeful race, and the man with the street car starter consoles himself with the reflection that his invention is a little better than anything previously developed in this line. If he prove very persistent and persevering, he manages, after much discouragement, to have his starter tried on a car. Somehow it does not give out all the power expected, so there must be something that needs adjustment, and the device is taken off for the purpose, but it is not put on again. Meanwhile, other men are seized of the same idea and a similar cycle is traversed.

The parties who bring out the car starters work on a mistaken notion. They know there is a good deal of power lost in stopping a car, and they think most of it can be preserved, which is a mistake. If the stopping appliance caught the car at its highest speed and destroyed the velocity within a foot or two, it might receive nearly the whole of the energy that was in the moving car. But this is not practicable. The device must stop the car by degrees, and in the space passed over a considerable percentage of the energy is dissipated by the wheels rubbing on the rough track, and the friction of the apparatus absorbs some power. When the losses are all summed up there is very little energy left in the spring to be available for starting the car. In places where cars run down steep grades where they require braking, there may be a possibility of absorbing energy enough to be useful in starting or even in helping the car up another hill; but for ordinary stops on a level no power can be preserved which will pay for the apparatus.—*American Machinist.*

Hemacite Door Knobs.

HEMACITE is the invention of Dr. W. H. Dibblee, of Trenton, New Jersey. Principal among the many uses to which it can be applied is the manufacture of door knobs. These knobs are equal, if not superior, to any made. They are moderate in cost though strong as iron. Four designs are used in the manufacture of their principal patterns — Eastlake, Saxon Shield, Japanese, and Star. Aside from their artistic appearance, they possess many other valuable features (which have made them popular with many of our architects, contractors, and builders), chief among which is the almost absolutely non-liability of getting out of order. A full line of these goods can be had in this city, and they are worthy of the attention of our architects before others are specified.

Bound volumes now ready. Price, $2.50 each. Street, Store and Bank Fronts. Price $4.00.

Extra Inducements to Subscribers for 1884.

Mechanic's Geometry, or the Science of Framing by the Aid of Card-board Models. With the aid of card-board models, and the rules and explanations given, the mechanic can readily learn the method of getting the length and bevels of every description of rafters, hoppers, etc. Stair work is also treated in a manner that at once arrests the attention of the student, and becomes an attractive study. This book will also be found useful, though possibly in a less degree, to those who have already become mechanics, but who have not learned the science involved in their trade. The main object of this work is the elevation of the working man to the dignity of the master mechanic. Price, $5.00.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT for $6.00.

The Artisan. Among the practical ideas in this work will be found the utility of the right angle, and its application in solving many useful problems. By means of a right angle the exact circumference of a circle is determined, hence. It also shows a simple and correct method for the measurement of boards, floors, and other surfaces. It is applied to lines of any length, and divides them into equal parts. It gives the cuts and lengths of rafters, braces, and other timbers in framing. There can be no doubt as to the value of a right angle and its utility in this connection. It is clearly illustrated in the *framing square*, a tool which solves nearly every problem in practical geometry. Price, $5.00.

Book and one year's subscription for $6.00

American Cottage Homes. This work has had an unprecedented sale in the United States since the reduction in price. The book is a large one, and contains many illustrations in the prominent later styles of architecture. Prices are given for which each design can be built. In California, however, the price in nearly every instance would have to be almost doubled to correspond to cost of work in this State. Being sole agents on this coast for the above work, we are prepared to make liberal terms to agents. Price, $3.00.

Book and one year's subscription for $4.25.

Complete and Comprehensive Details. This is the first work of its kind ever published in this country. The author justly remarks, "Ideas are as necessary as tools. Tools have no edge without them." These details furnish the mechanic with nearly eleven hundred ideas, and practical ideas that you want every day. Forty plates, 20x26 inches in size, are given for the small amount of $2.00. AGENTS CAN MAKE $5 00 PER DAY STEADY, HANDLING THIS WORK. Being sole agents on this coast, we are prepared to make liberal terms to canvassers.

Book and one year's subscription for $3.25.

Modern House Companion and Builders Guide. A hand-book of carpentry for the coat pocket. Among the illustrations and descriptions of the various kinds of works are the following: Pitch, hip, valley, and mansard roofs, angle rafters on French roofs, mitering circular mouldings, stair work, etc. Every mechanic should possess a copy, and thereby fit himself to become a master of his trade. Price, $1.25.

Book and one year's subscription for $3.00.

Grimshaw on Saws. The most complete work of its kind as yet written. A description is given of the manufacture of every kind of saw in use, with full directions for keeping them in order. Its chapters on filing and setting of saws, with descriptions of the best *sets* manufactured, are well worth the attention of every practical mechanic. New and enlarged edition. Price, $4.00.

Book and one year's subscription for $5.25.

Foundations and Foundation Walls. For all classes of buildings, pile driving, building stones, and brick, pier and wall construction, mortars, limes, cements, etc. Practical explanations of the various methods of building foundation walls for all classes of buildings, use of piles in building, etc. Price, $1.50.

Book and one year's subscription $3.25.

Lakey's Village and Country Homes. This is a large work, and just suited to those parties in the country who live too far away from an architect to secure his services. Designs are given for all prices of village and country homes. Several pages of details are also introduced. Price, $5.00.

Book and one year's subscription $6.00.

Builder's Guide and Estimator's Price Book. This work is chiefly intended to assist the Builder and Contractor in making estimates of the cost of work they may be competing for. It is written by the author of the "Steel Square and its Uses," which fact is a guarantee that the book is practical in its character. Price, $2.00.

Book and one year's subscription for $3.50.

Steel Square and Its Uses. Enlarged Edition. This work is just from the press, and those wanting copies should at once order them. It is a great improvement on the author's former work, containing much that is new to mechanics—some of the problems presented never having before appeared in print.

We are agents on this coast for this celebrated work, and will mail a copy to any address upon receipt of $1.00.

Book and one year's subscription for $2.50.

Science of Carpentry Made Easy. The work, *par excellence*, for every mechanic to have in his possession. It is thoroughly practical in its character, and contains much information not to be found in any other publication. It excels in its methods of obtaining the length and bevels of every description of rafters, both common, hip, and valley. Price, $5.00.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT for $6.00.

Moore's Universal Assistant and Complete Mechanic. This book contains 1,016 pages. There is hardly a mechanical subject that does not receive the attention of the author. Receipts are given for *shop secrets* in every branch of the trade. Well worth the price, $2.50.

Book and one year's subscription $3.75.

Gould's Carpentry Combined with Steel Square Problems. The author being a practical mechanic, has endeavored to make his ideas so plain that any one by reading, with a little study, can thoroughly master all the problems incident to the use of the Steel Square. Price, $2.50.

Book and one year's subscription $3.50.

Plaster, How to Make and How to Use It. It contains accurate descriptions of all tools and materials used in plastering; description and action of every variety of lime and cement; instructions for making all kinds of mortar, and doing all kinds of plain and ornamental plastering; many important recipes given. Price, $1.00.

Book and one year's subscription $2.60.

Workshop Companion. A collection of useful and reliable recipes, rules, processes, methods, wrinkles, and practical hints for the workshop. 164 pages of useful reading matter to all. Price, 35 cents. By mail, 40 cents.

Book and one year's subscription $2.15.

Practical Lessons in Architectural Drawing. There is not a draughtsman in this country but that will be benefited by the possession of this work. As its name implies, it is strictly a PRACTICAL WORK. Price, $2.50.

Book and one year's subscription $3.75.

Interiors and Interior Details. A large work, and as its name implies, contains details for every style of interior finish. The plates are all handsomely lithographed. Price, $7.50.

Book and year's subscription $8.75.

Hand Saws and the Art of Saw Filing. This book gives full information for putting in order all kinds of saws, from a carpenter's panel saw to a steam saw mill. Illustrated profusely. Price, $1.00.

Book and one year's subscription $2.60.

Lumberman's Hand-Book. Every carpenter, mechanic, lumber dealer, etc., should have this work in his pocket. Upward of 260 pages, filled with the most practical and useful information. Price, $2.00.

Book and one year's subscription $3.25.

Modern House Painting. A new work of novel design, presenting numerous elevations of houses in colors precisely as they will appear when finished. Price, $5.00.

Book and one year's subscription $6.00.

Modern Perspective. A perfectly new work. Should be studied by those who seek to excel. It is intended for the architect as well as the draughtsman. Price, $6.00.

Book and one year's subscription $7.25.

Monckton's Practical Geometry. A completely new work, comprising problems of practical utility to the workmen. Price, $1.00.

Book and one year's subscription $2.50.

Carpenter's Pocket-Book. The price of this work has been reduced to 50 cents.

Book and one year's subscription $2.25.

Modern Architectural Designs and Details. The plan of this work is very comprehensive in its character. Numerous designs are given illustrating the Eastlake, Elizabethan, and Queen Anne styles of architecture. Complete plans of each, together with full and comprehensive details, are produced in a manner that will gratify the tastes of any architect or property owner. Price, $10.00.

Book and one year's subscription for $11.00.

Detail Cottage and Constructive Architecture. To the general country mechanics, this work is invaluable. Every part of a building is thoroughly detailed including store fixtures, counters, fences, etc. Price, $10.00.

Book and one year's subscription $11.00.

Artistic Homes. A. W. Fuller, a well-known architect, has given to the general public, for a small price, a very neat work containing 44 plates in the Queen Anne style of architecture. Price, $3.50.

Book and one year's subscription $4.75.

Rural Church Architecture. Mechanics and others, in the country, will find in this work a great many plans for churches of moderate cost. Price, $4.00.

Book and one year's subscription $5.25.

Practical Perspective. With thirty-six Double-page Illustrations. Cloth $1.5[illegible]

Street, Store, and Bank Fronts. This book is complete upon the subject of which it treats. Price, $3.50.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT $4.75.

Wooden and Brick Buildings. Two volumes, forming a larger collection of designs for buildings than any work yet issued. Price for the two $18.00.

Two volumes and one year's subscription $18.50.

Village Builder. The editions of this work are almost exhausted, and copies are scarce. Price $10.00.

Book and one year's subscription $11.00.

Practical Carpentry. As its name indicates, this work presents practical answers to those questions that so frequently vex the mechanic. Price $1.00.

Book and one year's subscription $2.60.

American House Carpenter. This work, by Hatfield, is justly regarded as the standard work on carpentry. Price, $5.00.

Book and one year's subscription $6.25.

Architect's and Builder's Companion. A new edition, by Vodges. Every mechanic should have one in his pocket. Price, $2.50.

Book and one year's subscription $3.50.

Model Homes. A work containing a great many designs in the prevalent New England styles. Price, $1.00.

Book and one year's subscription $2.50.

Building Superintendence. A new work and one that should be in the hands of every architect, contractor, and student. Price, $4.00.

Book and one year's subscription $5.00.

Cottage Homes. A new work containing numerous designs of styles in vogue in New York and vicinity. Price $5.00.

Book and one year's subscription $6.00.

Handrailing and Staircasing. A complete set of Lines for Handrails by "Square-cut System," and Full Practical Instructions for making and fixing Geometrical Staircases. By FRANK O. CRESWELL, of the Liverpool School of Science, Medallist for Geometry. With upwards of One Hundred Working Drawings. Cloth $1.50.

Book and one year's subscription $3.00.

Drawing for Carpenters and Joiners. With Elementary Lessons in Freehand and Object Drawing. Containing 250 illustrations and Drawing Copies. Cloth, $1.75.

Book and one year's subscription $3.25.

Drawing for Bricklayers. With the Elements of Freehand, Object and Plan Drawing. Containing Two Double and Thirty-two Single Pages of Illustrations adapted for Architectural Drawing. Cloth $1.50.

Book and one year's subscription $3.00.

Drawing for Cabinet-Makers. With Lessons in Ornamental and Object Drawing; Elementary Instruction in Water-Colored Drawing. Containing Twenty-four Single and Five Double-page Plates. Cloth $1.50.

Book and one year's subscription $3.00.

Drawing for Stonemasons. With Elementary Lessons in Freehand and Object Drawing and a concise History of Masonry. Containing six Double and Twenty-five Single Pages of Illustrations. Cloth $1.50.

Gothic Stone Work. Containing the History and Principles of Church Architecture, and Illustrations of the Characteristic Features of each Period, the Arrangement of Ecclesiastical Edifices, etc. With Seven Double and Eighteen Single-page Plates. Cloth $150.

Building Construction, The Elements of and Architectural Drawing. With 130 Illustrations. 128 pp., Cloth $1.25.

Book and one year's subscription $3.00

Linear Drawing and Practical Geometry. With about 150 Illustrations, and six Whole-page Diagrams of Working Drawings. 128 pp., cloth, $1.25.

Linear Drawing and Projection. The Two Vols. in one. By E. A. DAVIDSON. Cloth $1.75.

Cutting Tools Worked by Hand and Machine. By R. H. SMITH, Professor of Mechanical Engineering, Sir Joseph Mason's College, Birmingham. Price $1.50.

Book and one year's subscription $3.00.

Carpenter and Joiner. This most excellent work, by Riddell, is well worth study by every one who desires to become proficient in the mechanic's trade. Price, $7.50.

Book and one year's subscription $8.50.

American Stair Builder's Guide. With the aid of the rules and illustrations given, the young mechanic can, in a very short time, be enabled to lay out any and all kinds of stair work. Price, $3.00.

Book and one year's subscription $4.50.

Systematic Drawing and Shading. By CHARLES RYAN. Giving Practical Lessons on Drawing. Cloth, $1.25.

Loss of Trade Through Drunken Mechanics.

A REPORT comes from Glasgow, Scotland, which indicates that the Clyde ship building and machine trade are losing orders through a cause very discreditable to the workmen. When work is brisk in that district and wages high, a great many of the mechanics are in the habit of remaining out on drunken bouts for two or three days each week. Many of the very best hands indulge in this practice. It has become so serious as to interfere with the regularity of builders in finishing orders, and several cases have recently happened of work going to continental firms because those of the Clyde could not be relied upon to finish the contracts on time. The trade unions have done all they can to discourage the prevailing practice of periodical spreeing among members, but they do not seem to effect much good. The real trouble is that drunkenness receives too much apology in all quarters of the British Isles. There may be some improvement now, but we know that twenty years ago nearly all British machine shops had certain good workmen who might be depended upon to go on a drunk when their services were most needed. And in many cases the whole shop would be inconvenienced till they were pleased to come in. The fashion there was to tolerate this nuisance. The fashion in this country of discharging men who display greater attention to whisky than to their work is better for all concerned. Changing men on certain jobs may cause great inconvenience in a shop for a few weeks, but it is better to indure that than the continual annoyance of recurring periods of absence through dissipation. If the Clyde ship builders and engineers would adopt the American policy of dealing with drunkenness they would effect its cure after a time.—*American Machinist.*

Rooms 11, 12, 13, No. 240 Montgomery Street.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.

Back Cover, outside, each insertion, $2.00 per square.

Page preceding reading matter, $1.75 per square.

Page following reading matter, $1.50 per square,

Inside Pages, each insertion, $1.00 per square.

Full Page, inside, one insertion, $40.00.

Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

A LUMBER BONE YARD.

How High Rates Are Maintained.

"A LUMBER Bone Yard" may be a singular title for an article in a journal of the character of the CALIFORNIA ARCHITECT, and yet there is a world of meaning, not only to all of our readers, but also to all consumers of lumber, in the full explanation of the meaning of the term quoted, viz:—"A Lumber Bone Yard."

Many have wondered how, or by what means the lumber manufacturers have been enabled to fix a scale of prices, and at will, add to the rates whenever they thought the dear good public was not paying enough for material. When such a "squeeze" has been made, it was generally given out that workmen in the woods demanded higher wages; owners of tugs required so much more for their services; feed for the logging teams was scarce and so increased expense being necessary, lumber would have to be raised accordingly; and so on *ad libitum*, excuses were made for the increase of the schedule rates.

The public can readily understand the fact of the increase of prices, but it has not been made quite so plain to them how these rates have been so uniformly maintained, considering the fact that there are so many dealers in lumber in the City. The explanation is simple—THE EXISTENCE OF A "LUMBER BONE YARD" ENABLES THE MANUFACTURERS TO READILY ABSORB ALL THE SURPLUS LUMBER, AND THUS MAINTAIN HIGH RATES.

In the southern part of the city, very conveniently located for the purpose for which it is intended, is situated the "Bone Yard." It enjoys splendid water privileges, and vessels can unload the surplus lumber very handily. The yard at present is nearly full, and there are arrangements being made for a location for yard No. 2. How many of these will be needed in the future, time alone can tell.

There are twelve firms belonging to the Pine Manufacturer's Association, and these support and provide the necessary capital for the maintenance of the yard. This is done by an assessment of a certain sum upon every thousand feet of pine lumber manufactured. In case this should prove insufficient, an extra assessment is levied in order to raise any required amount.

The advantages to the manufacturers are many and great; the retailer can put his hands in his pocket, quietly look on, and save what he can. The *modus operandi* is about as follows: Several cargoes of lumber may arrive for which there is no demand. The small mills may send several hundred thousand feet at a time when the market is fully supplied. Should this be thrown upon the market a break would occur and down prices would tumble. This would not suit the *compact twelve*, and so the cargo is bought as a whole and transferred to the bone yard. The price paid by the association is seventy-five cents cash less than the cargo rates per thousand. All the pine lumber coming into the harbor for which almost immediate use cannot be found, is thus bought at seventy-five cents less per thousand than the cargo rates, and as this is always cash, the small mills prefer the price thus obtained to a vain endeavor of trying to break the market.

Lumber is now being piled up by the million feet, and at the time of the writing of this article, several vessels are waiting to be unloaded. Under much pressure, even rich as the manufacturers are, the strain made on their treasury by their efforts to control the market, would become too great if there was not a way in which it could be relieved. This is done by sending a ship load to the Sandwich Islands, Central America, or anywhere else for a market. The price such cargoes bring is not much of an object, as long as expenses all around are cleared. It is on the same principle as the farmer charging more for his produce in the orchard than he obtains for the same article in the city after paying the necessary expenses.

There is rather a comical side to the matter, however, and one that at times is taken advantage of by those that are regarded as shrewd. After a schooner has been tied to the landing and help ready to transfer the cargo to the yard, it is a very easy matter for a barge or scow to come alongside and load at *cargo rates* such lumber as may be required, this act being regarded as buying by the cargo. In this case *rates* are somewhat indefinite.

From the above explanation the *dear good public* will readily understand how it is that the manufacturers have such a laborious time in their endeavors to adopt a periodically gradual ascending scale of prices, one with which they, the public, will be satisfied and do their utmost to meet the different raises with cheerfulness and a prompt appeal to their bank account.

The old saying that capital will tell, is true in this case. We sincerely wish it were otherwise, as we hear of many buildings being delayed on account of the price of lumber. That material being high, with labor, hardware, etc., tending the same way, a stop is put to many improvements that would otherwise now be in progress.

Were, in our opinion, the proceedings of the

association just, we would be the last to enter a protest against any rule that should be made; knowing as we do, however, that there are members of the association who count their money by the hundreds of thousands lying idle in the bank, made from an exorbitant profit on an essential material of the growth of a city, we feel justified in uttering our protest against some of the methods used to maintain high rates. Fifteen per cent. off the prices now charged would leave an ample profit to the manufacturers, and would be a material benefit to those erecting buildings.

S. F. Chapter—American Institute of Architects.

THE regular monthly meeting was held at the usual place, on Friday evening, February 1, 1884.

An unusually large number of members were present. President John Wright in the Chair.

Committee on a seal for the use of the Chapter, reported that they did not deem it wise to place the design for seal in the hands of the students. They had engaged the services of F. Marion Wells, who was preparing a model; when finished, the committee would have the seal prepared from the model.

Committee on plumbing reported that they had met the members, composing the Board of Health, and that the latter favorably received the ideas advanced by the architects.

Mr. Pissis reported his class as getting along finely. He called the attention of the members to the prizes offered by the President and the Chapter four months ago. Mr. Pissis said his class would be ready to offer drawings in about one month.

Mr. Curlett suggested that book prizes be offered instead of money, and four prizes instead of three.

Mr. Macy suggested diploma prizes in place of books. But, on discussion, it was decided that the classes were not far enough advanced for diplomas.

After an animated discussion, it was decided that four book prizes be given to the students showing the most marked increase during the time they have been under the tuition of the class teachers. It was left to the latter to make the recommendations and select the prizes. Mr Wells was added to the committee. It was decided, if necessary, the committee could purchase books to the amount of $50.

After a lengthy debate, it was definitely settled that *no student or draughtsman can belong to the classes unless the architect for whom he works, is a member of the Chapter.*

Committee on incorporating reported that as soon as the seal was obtained, the Chapter would be incorporated.

Warren H. Williams was unanimously elected a member of the Chapter.

Proposition of L. Stone was received as a student member. Referred to Henriksen, Moore, and Macy.

A lengthy debate then followed in regard to the premiums offered by the "Pioneers" for their new building to be erected on Fourth Street. Mr. Macy had the honor to belong to the Pioneers, and from what he knew of the man to whom that Society would owe their new building, he did not think that if he were alive, such ridiculous offers of premiums would be made. The labor required for the production of the drawings was far in excess of value of the premiums.

Mr Henriksen claimed life-membership in the Pioneers, but he did not propose to enter the competition. He would do so, provided that the successful competitor be awarded the superintendency of the building, with $500, and $450 for second and third premiums, and plans returned to the latter two.

Mr. Pissis then offered the following resolutions:—

1. *Resolved*, That the members of the S. F. Chapter of the A. I. A. refuse to compete for the proposed new building of the Pioneer Association, unless the conditions for the competition are altered to the satisfaction of this Chapter.

2. *Resolved*, That a committee be appointed to confer with the committee of the Pioneer building, in relation to the competition and whose duty shall be to obtain more acceptable conditions.

3. *Resolved*, That a copy of these resolutions be forwarded to the committee advertising for competition plans, and that every member of this Chapter be notified of these resolutions.

4. *Resolved*, That the President be requested to call a special meeting within a week, which shall be devoted to the subject of architectural competitions in general, and to the present one in particular.

Discussion then ensued upon the objectionable features in the pamphlet containing the offer for premiums for plans of the Pioneers' building. The main points were as follows:

The committee reserved the right to reject any or all plans.

This very bad feature should be changed so that the three premiums offered would be given for the three best plans.

The committee desired the architects to name their own fees.

This feature opened the way to any incompetent architect, by giving them a chance to place their fees at one, two, or three per cent. Professional services have a standard value, and by common consent the world over, five per cent. is the regular fee of all first-class architects. Nothing less than this should be given.

The committee called for contractor's estimates to verify those made by the architect.

This feature was especially condemned, as no first-class contractor would prepare estimates for such a large building much short of $100. This the architect would have to pay; the committee from Pioneers, by rejecting any and all plans, would thus leave the architect minus all moneys paid for contractor's estimates, besides their own time and trouble.

The adoption of the first premium plan did not give the successful architect the right to superintend the building.

Thus after months of study and labor the successful competitor might have the pleasure (?) of seeing some one else superintend a design, the details of which he would be in entire ignorance. This fact debarred at once first-class architects from entering the competition.

The above were the principal objections raised, although many others were noted. The following resolution was then adopted.

Resolved, That it is the sense of the S. F. Chapter American Institute of Architects, that it is opposed to enter into any such arrangements as have been offered by the Building Committee of the Pioneers' Association.

Unanimously carried. A committee was then appointed to wait upon the Building Committee of the Pioneers, and endeavor to have the conditions of the competition changed in conformity with the proceedings of this meeting.

Mr. H. G. Knapp, an architect from New York, was invited to address the meeting. He alluded to the fact that he had entered many architectural competitions, and was fully conversant with the conditions imposed in Eastern competitions, but in all his experience he had never been called upon to present plans, under such ridiculous propositions as have been offered by the Pioneers' Association. He considered it an attempt to make architects cut their own throats by naming the amount of their fees.

It could be also styled architects *vs.* manual labor, as all estimates would have to be verified by a contractor. He most certainly would not enter the competition under such terms as were presented in the pamphlet.

The original resolutions were then put to a vote and unanimously adopted, and the following-named gentlemen appointed as the committee to wait upon the Pioneers: Messrs. Wright, Curlett, Macy and Pissis. The whole subject matter was left entirely in the hands of the committee.

"Chock Full of Days' Works."

THAT is an interesting and suggestive anecdote that is told of the young countryman who asked the hand of a young girl in marriage from her parents, and in response to the inquiry whether he had any property, replied that he had not, but that he was "chock full of days' works." These are the true source of wealth, and the surest basis of credit. The person who has health, energy, ability and honesty, who is full of "days' works," can generally be trusted. To such a person the extension of credit is a benefit which words cannot measure. The best help in the world is that which helps one to help himself—which puts in his hands the tools wherewith to carve the fortune of life; and this is oftenest done by the judicious granting of credit.—*American Artisan.*

A PROCESS FOR FROSTING GLASS.—To give glass this appearance, it is only necessary to coat it with the following composition: Sulphate of magnesia diluted in beer, with a little dextrine added.

George H. Wolfe.

SECRETARY S. F. CHAPTER OF ARCHITECTS.

WE publish in this issue the accompanying likeness of the Junior Editor and Business Manager of this Journal, not because of his being such, but as an officer—Secretary—of San Francisco Chapter of Architects, to which position he has been twice elected by the Chapter, in addition to his serving in the same capacity in the Pacific Coast Association of Architects during its existence.

Mr. Wolfe was born in the city of Baltimore, Md., December 29, 1843, and is therefore a little over forty years of age. He arrived in this city in the early part of May, 1852. Attending the public schools, he finished the scholastic course by graduating from the high school cotemporaneously with several of the gentlemen engaged at the present time in the practice of architecture on this coast.

Upon leaving the high school, he applied himself to the study of architecture in the office in which he is now junior partner, remaining there for some time, until smitten with the "mining fever," of '63, which at that time raged throughout the State as a great moral and financial pestilence, exciting and overpowering the better judgment of thousands who were then following avocations and pursuits which if adhered to, would in due time have yielded a pleasing if not bountiful harvest of profit and comfortable wealth. But the excitements and allurements of the times gaining the mastery, he wended his way "to the mountains," part of the time at Virginia City, and part in California, only to share the disastrous reverses which in 1864 carried down and crushed to poverty and want so many who were by the catastrophes of the times swamped and ruined. After this he applied himself to practical constructive pursuits, until the early part of 1880, at which time he returned to this city and became associated with, and soon after was admitted as full partner in the publication of this Journal, and as a member of the architectural firm of Wolfe & Son.

Those who know him personally will accept the fact that he is earnest, attentive and diligent in the department of the editorial and managerial work specially under his care, and in assisting in placing this Journal upon the pedestal of pre-eminent success, and achieving for this,—the pioneer architectural publication upon the Pacific Coast,—a reputation world wide for its correctness and fairness in the presentation of all matters connected with building interests and other relative matters and sciences.

GEORGE H. WOLFE.

The object of our series of likenesses is in no way intended to mitigate adversely to any member of the profession nor in Chapter fellowship, but to provide a practical means whereby the features of the Chapter members of the present period may be preserved and handed down to coming generations. This will be the case, as thousands of the yearly issues of this Journal have been bound and placed in private and public libraries, to remain as books of interest and reference; so that when we who are now occupying our time and energies in architectural pursuits shall have passed beyond present conditions, those who shall fill our places will have it in their power to look upon the picture countenances of those who were before them.

In addition to the Chapter members, we shall be pleased to re-produce the likenesses of other prominent and worthy gentlemen in the profession, feeling that "not to the Chapter and Chapter members alone belongs all the glory" of architectural worth and abilities, but that among those who have not indentified themselves in the Chapter work, there are worthy and excellent gentlemen whose likenesses are entitled upon professional considerations to rank with those who have assisted in founding and sustaining on organization which we believe is destined to accomplish a vast amount of good in a general sense—as far as the profession is concerned; and especially toward the student of the present time, in the promulgation of advanced thought, and the elevation of the profession to that high and honorable standing which its greatness and magnitude demand; and in perfecting and fulfilling the several excellent purposes contemplated by, and under the fostering care of the Chapter.

A Good Retort—Picture Architects.

ONE of our young architects, somewhat noted for his lack of harmony with members of the profession who have worked at the mechanical as well as the professional part of their calling, while conversing with a prominent citizen in regard to a building shortly to be erected, took particular pains to run down another architect who had worked his way upward, after first becoming conversant with the use of the saw and jack plane. "Why, sir," said our young man, "Mr. —— is nothing but a *carpenter* architect."

The answer came, short and decisive, "Better that, sir, than a *picture* architect."

The young man subsided and was not engaged, the "*mechanical*" architect receiving the preference.

Engravings made from Photogrphs. Address California Electric Engraving Co., 240 Montgomery St., Room 11.

Country Architecture.

BY A. CURTIS BOND.

THE illustration upon the opposite page shows the perspective and plan for a country cottage.

The general outline is sufficiently out of the ordinary to make it noticeable, a feature by no means to be ignored in country architecture. Painted in warm and striking colors, this building should be unusually striking and effective, but such a design requires more, I think, than a plain house, good judgment in laying on of exterior ornamentation and decoration.

The specifications for this building the architect suggests should be as follows:—

Plan.—To be as shown at length in the sketch.

Timber.—Sills, 4x10; posts, 4x8; interties, 4x6; plate, 4x6; first and second story floor joists, 2x10; third tier, 2x8. All joists supporting partitions to be 3x10; rafters, 3x5. All doors and window studs to be double, and above to be of good sound spruce timber.

Framing.—All frame to be well pinned together, and all partition, where possible, to rest on partition below and not on floor joist. All joist of ten-foot space to have one row of bridging.

Exterior.—To be first covered with mill worked, tongued and grooved hemlock boards, then with good quality of sheathing paper, over which lay pine clapboards, and where shown on perspective sketch, to have rounded shingles; all to be free from loose or black knots. Cornerboards 1¼x4 inches, watertable, 1¼x6.

Cornice.—To be formed where shown and to project not less than one foot eight inches.

Roof.—To be covered with hemlock boards, then with blue roofing slate with corners trimmed off (or shingles may be enployed at builders option). Ridge to be covered with zinc, valley of best brand tin, cutter formed at eaves with leader of sufficient size to carry all waters from roof to cistern.

Plumbing.—Fit up W. C., bath and stationary tubs, where shown on plan.

Painting.—All woodwork painted two coats of best white lead and linseed oil, of such color as may be selected.

Mason work.—Foundation nine feet high, cellar eight feet high and three and one-half feet above grades. Chimney where shown on plan and carried up above roof.

Specifications and drawings are intended to correspond so that any work shown on the drawing and not mentioned in the specifications, or *vice versa*, is to be executed the same as if it were particularly expressed.

. . . . . .

There has been considerable comment and no little diversity of opinion upon a design submitted for the building of the American Institute of Architects in this city. The suggestion has been made that the *facade* employ and present examples of all the preceding styles in architecture, or, as the architect says who submits the design: "In a building designed by occupancy by the American Institute of Architects, I consider that no *motif* could be more appropriate than an embodiment of a history of our art. I have therefore attempted to solve the problem of designing our historic *facade*, where every epoch in architectural history shall be represented by details from the best examples now obtainable, following each other in regular and orderly sequence. Thus, the first story represents the prehistoric period; in the second the Greek appears, followed by the Roman classic, closed in by the moresque arch. . . . Commencing with the Byzantine I have introduced the Romanesque, followed by the three periods of the Gothic. . . . Following the Gothic, which in the last period covers the whole width of the *facade*, typical of its universal acceptance by the building world, I have introduced sixteenth-century *renaissance* with modern *renaissance*, including Victorian Gothic, and the latest phase of all architectural design, Queen Anne. The gable is surmounted by Foley's statue of 'Caractacus challenging the World,' thus symbolizing the fact that whatever may be said of American skill and learning, there is nothing the matter with our ambition."

As may be surmised, this design presents a marvelous combination of all that is possible to gather from the permanent and refuse features of all manner and kinds of the worlds as architecture. The Indian rock-temples and the Stonehenge are patterns for the pre-historic periods, and then the tide of history aspires to the Temple of Dendero and Karnoc, the hall of Xerxes, the Erectheium at Athens, the Pantheon, St. Sophia, Canterbury Cathedral, Notre Dame, and so on down to Vanderbilt's new house in New York, all have been laid under contribution to complete a genuine *alla podrida* of brick and stone. Yet withal it is harmonious, this is the marvelous part of it, it demonstrates that an unlimited amount of appropriating may be indulged in without even the courtesy of changing the forms appropriated, and yet produce a presentable, even a handsome appearance. Of course this design may never be accepted, or even considered, it probably never will, yet it is an original idea, and one worthy not only of encouragement but of imitation in a certain way. There is no American style, there is not even a nineteenth century style, and our architects cannot do much better than devote some of their time and talents to bringing forth one. What can be shown in the year 2100 as the prevailing form of 1900? Nothing distinctive certainly, nothing but a rehash of the *renaissance*, or an occasional resuscitation of early English and Queen Anne. Why would it not be well to accept the hint thrown out by the architect who made the design I have referred to, and if we must adhere to the antique take a quantity of antiques and have at least the merit of new combinations and temerity in making them.

. . . . . .

An English architectural paper has devoted considerable space recently to a comparison between English and American architects, showing, it must be said, a particularly pleasant appreciation of the talents of the American. A letter from their New York correspondent very cleverly closed the case by saying that in this country the architect worked much harder than in England; he had no half-holiday at the end of the week, and must exercise his wit and ability to its full capacity if he would compete with others in his line. The correspondent also took occasion to revert to the very damaging custom prevailing in the old country of admitting students to the architects' offices and making use of their services, regardless of their adaptability for the profession or their ability to learn it, simply because the students' parents pay a stipulated sum to the architect *to tolerate* the learner. Here, on the contrary, the student is paid for any services he may render, and in consideration of such payment he must possess an adequate amount of intelligence and capacity. We have too much business to demand our attention to spare time to incompetent assistants. This is as it should be.

"THE fashion now is decidedly in the direction of wall lamps," says a London paper. "Some are of great beauty. Two of a set I have seen are opal-tinted glass and two rose-colored. The sconces in which they are fixed are fitted in frames of mirrors, with beveled edges. These, in their turn, are framed in brass, beautifully chased. These lamps are placed near the four corners of a pretty drawing-room, the opal-tinted and the red alternately. As the wall paper is a pattern of daisies in gold and pink on a ground of warm cream color, the effect is very good. Candles with pink shades are scattered about the room in pairs, and at a table in a corner a low reading lamp sheds a softened radiance upon books and writing materials."

MORE AFFECTATIONS NAILED.—"That's right young man, say 'gaz' just because you heard some one else say it. Don't look into a dictionary to find there is no such word in the English language. Just keep right on saying it and people will know that you fasten your scarf pin by note, but pronounce your words by ear. For the same reason, do not say vase, say vawz. Then, in speaking of yourself, pronounce the double s like z, to make yourself rhyme with your kind of gas."—*Burlington Hawkeye.*

CLINKERS may be loosened from fire-bricks by throwing in the fire box, when very hot, two or three quarts of oyster or clam shells, or a less quantity of salt, allowing the fire to go out; then cleave off the clinkers.

PAPER gas pipes are made. The fact that they will not freeze up will be sufficient to turn all plumbers against them.

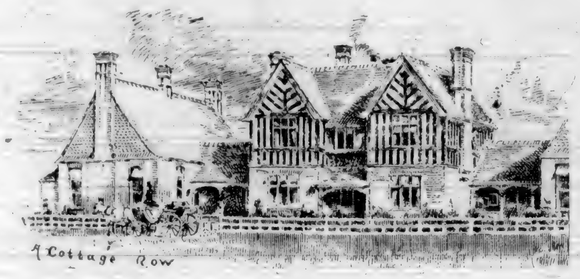
A NEW PHASE OF EASTERN ARCHITECTURE. See Page 26.



Illicit Commission.

OWING to protracted illness, we have not been able to notice in due season several matters of interest which have come to the surface within the past two months.—SENIOR ED.] Among these is an article which appeared in the London *Truth*, October 18, 1883, in which assertions are made and insinuations thrown out in reference to architects obtaining and receiving illicit commissions, which if true according to the writer's one-sided views of the case, would place the personals of the architectural profession in all civilized countries in no enviable light. The matter was taken in hand by the *Royal Institute of British Architects*, and a positive denial of the charges made, as far at least as the reputable and competent, and the larger proportion of the profession, are concerned.

Correspondence passed between the officers of the institute and the editor publishing the slanderous statements, with the result that the offending Journal, *unable* or *unwilling* to substantiate its charges, was placed in the position of a common villifier upon *speculative, presumptive, and unsustained by proof-assumptions* of a state of *possible* facts, applying and spreading the odium of moral irregularity over the garments of all alike, reserving no virtues for the larger proportion of truly honorable men in the profession, whose hands are unsoiled as to any unjust or dishonorable transactions as far as their cliants' interests are concerned. The controversy has been entered into and reviewed by some of our European and Eastern contemporaries, and several interesting articles, editorial and correspondent, have appeared, sustaining the proposition that while there may be, and doubtless are, men practicing the profession in all parts of the world who would feel but slight if any compunctions of concience at anything they might do within the law to fill their purses with coin, no matter how obtained. There are also a very large proportion, and we hope a large majority of architects against whom the *Truth*'s charges cannot be sustained.

The matter of "trade discounts" is given prominence in the article in question, and the effort made to make it appear that architects receive the financial advantages arising from this trade rule. But it seems to us that no man of respectable intelligence would, upon due reflection, assume any such theory. If the architect in any particular case occupied the position of purchasing agent for his cliant, then the opportunity *might* be utilized by him as such agent in the purchases made. But all such opportunities disappear when the purchasing is done by the contractor in his own interests. A specificatian may call for Brown's patent this, or Jones' patent that, etc., upon which there may be trade discounts. But every intelligent contractor understands the fact of such discount as well as the architect, and every contractor is sure to avail himself of the benefits arising therefrom, thus closing the door against the architect as far as receipts from such sources are concerned. As a rule, the intelligent classes of contractors are far better informed as to prices, trade discounts, etc., than architects can very well be. For a knowledge of market values, costs, and prices is one of the most important and necessary qualifications to successful contracting. And when men's interests are surrounded with doubts and uncertainties, as in the case of competitions, which often result in the low bidder being but a few dollars and sometimes only a few cents below the second, every advantage of trade discounts and all others are utilized to the fullest extent, and the owner, not the reputable architect, receives the benefit of such trade rule.

OWNERS AT FAULT, AND ARCHITECTS FOOLISH.

Whatever grounds there may be for charges and complaints against a *portion* of those *practicing* architecture in San Francisco, and to a certain extent by influence reaching every member of the profession, the fault is largely on the part of owners in seeking and often succeeding in breaking down the legitimate charges for architectural services; and architects who yield to the grinding down process, and undertake work for no more, and perhaps less than the *actual cost* of producing the plans, specifications, and details, assume one of two positions, *first*, of being absolute business simpletons, or, *secondly*, caring nothing for the understood pay to be received from the owner, relying upon the outside resources possible of manipulation, by and through which the owner is made to pay, *indirectly*, the full legitimate commission of five per cent., an perhaps much more. As long as owners will run to and accept the services of that low order of architectural pretenders who neither possess nor care anything about moral integrity or architectural qualifications, just so long will irregularities exist; and we heartily rejoice every time we hear, as we often do, of owners being badly used by those whose services they have accepted upon the basis of pretended cheapness.

Cheap architects, *cheap* doctors, *cheap* lawyers, and every other *cheap* thing is within the same category, intrinsically of little value, and cannot be made to fill the place of the better kind. And it is greatly to be regretted that the services of good, faithful and competent architects are under-estimated by so many owners, and that trustworthy and honest men in the profession are refused engagements simply because some one else, perhaps of infinitely inferior qualifications, is willing to render services at almost any rates of compensation that may be offered them.

Lincrusta-Walton.

A SPECIES of decorative material known as Lincrusta-Walton, an English production, is meeting with considerable favor where it has been introduced. The material is composed of linseed oil, pulverized cork, and other ingredients, mixed and pressed into carefully made moulds of various designs. It is said to be impervious to moisture, and if this be true, it will prove a valuable addition to decorative material. It is a pleasant substance to paint upon, and the artistic patterns into which it is stamped render the painter's work easy. It is put up like wall paper, with a strong paste made of glue and paste. The chief drawback to its use is its high price. This is, of course, very much less than wood carving, which it resembles in effect, would be; but as compared with wall paper and some of the other cheap means of decoration, it is considered expeusive. It bids fair, however, to find its way into some of the better grades of buildings, when its merits become fairly known. Perhaps its cost will be reduced in time, when the demand for it shall have become large enough to warrant its manufacture on a larger scale than is done at present. We are informed that furniture and picture frame manufacturers think of substituting Lincrusta for the carved wooden, or raised ornaments on their products, on account of its cheapness and clearness of outline.

ACCORDING to the best scientific authority on the interior finishing of dwelling-houses, wall-paper should not be manufactured, as has always been the case heretofore, in a manner to be perfectly air tight. The reason of this is that, hygienically considered, the walls of a house, like the materials of clothing, should be porous, having free intercourse with the open air. It is also believed that water proof paper such as has come into such extensive use causes increased dampness of the walls, the stoppage of all circulation of air necessarily preventing their drying—this prolonged dampness of the walls being unhealthy and productive also of other evils.

Henry C. Macy.

TREASURER OF SAN FRANCISCO CHAPTER.

PIONEERS of San Francisco include those who came to this city prior to the admission of California as a State into the Union, and the subject of this sketch is one of the rapidly decreasing numbers that are justly known by the term Pioneer.

Mr. Macy was born on Nantucket Island, on the 4th of August, 1821. Having a natural gift for the use of tools, he was early apprenticed to the carpenter's trade. His career as a contractor began in the city of Providence, Rhode Island. He left that place to establish a sash and blind factory for Mr. Davenport in New Bedford.

Shortly after this his native place was almost destroyed by fire, and he went home to devote his time to rebuilding the burnt district. About this time the gold fever in California broke out, and his attention was attracted towards the New El Dorado. The staid New England ways had no more attraction for many ambitious and energetic men, and so, in company with scores of others, Mr. Macy started by the way of Cape Horn to the Golden State. He arrived in San Francisco in the fall of '49, a memorable year in the history of this State.

For ten years Mr. Macy practiced his occupation as a master mechanic. We also find him at this time closely identifying himself with the Mercantile and Mechanic's Institute Library, and the facilities offered by these institutions were duly appreciated and taken advantage of by Mr. Macy, in preparing himself for the profession which he had chosen for his future course.

In 1860 he began his first work as a professional architect, and since then has attained a well-deserved rank in the profession. We say well deserved, because we think the title well earned. From 1849 to 1860 was a very stirring time in the history of California, and to become a professional architect, much time and study was required, and when a person passes through such busy times as were then experienced, giving up his evenings to study, he is honestly entitled to due credit.

Mr. Macy, in September, 1883, was elected for the second term as Treasurer of the Chapter. He is one of those who can nearly always be counted upon as being present at every meeting. His whole soul is in the idea of a general spirit of harmony among all the members of the architectural profession. He is also one of those who are truly earnest in encouraging the younger members to adopt a high standard for the future. The "traveling studentship," mentioned in our last issue, receives his warmest support.

During the past twenty years, several different architectural organizations have been started, but owing to the lukewarmness of many of the members, they gradually went out of existence. In all these different attempts to establish a society, Mr. Macy was very earnest in his endeavors to place them on

HENRY C. MACY.

a sound basis, but his efforts were not as successful as they should have been. After a silence of several years, the present movement was started, and we again find Mr. Macy ready and willing to devote part of his time and energy to the formation of a Chapter. This time he has seen the effort a successful one, owing to the general unanimity among those engaged in the profession, with this advantage, however, over former attempts: A successful architectural journal, devoted specially to the architectural and building interests of the Pacific Coast.

Mr. Macy's conversational powers are such as to render him a pleasing companion, and his extensive researches of ancient and modern historical and scientific works, enable him to deliver very entertaining addresses upon any subject connected with the profession.

Domestic Architecture.

OUT of our century of bareness in art we have at least gained this truth: that no art will at present flourish here which does not aim at the benefit of the million. Domestic architecture will, therefore, be our first general artistic success. For every fourth or fifth man promises himself, some day, the best house he can afford. And when he learns that architecture is not a costly superfluity, but the soul of his building, which moulds the brick or wood of its bodily form into beautiful, because truthful expression, our noble orders will begin to appear. To be American they must be inexpensive. For the theory of republicanism is, that the only worthy ends of earth —culture and refinement— are attainable without wealth. The mad haste to be rich, so characteristic of this time, springs largely from an awakening but still ignorant love of the beautiful, which imagines that its price is money. The remedy lies in the propagation of the gospel taste. That declares the first law of beauty to be honesty of intention. Thus a house which costs three thousand dollars may be as good art as one which costs thirty thousand dollars, if it will own its cheapness and derive its beauty from true proportions and harmony of hues. The moment it pretends to an effect which its cost forbids, it is remanded to the great limbo of the vulgar.

What is true of the house is true of its furniture. Cost has little relation to beauty, whose first element is honesty, grace of form, and richness of color following after. Thus a kitchen poker may be artistic, if made in the manner and of the material exactly adapted to its use, while a pink satin and gilded parlor chair is inartistic, because too fine to be sat upon.—*Builder and Wood Worker.*

THE best way to clean mirrors, the glass of pictures, etc., is to take a soft sponge, wash it well in clean water, and squeeze it as dry as possible; dip it in some spirits of wine, and rub over the glass, then have some powder blue tied up in a rag, dust it over your glass, and rub it lightly and quickly with a soft cloth; afterward finish with a silk handkerchief.

PLINY says that four-wheeled carriages were invented by the Phrygians.

The Trade Element in Professional Practice.

IT has been frequently and by no means inconsequently asked whether architecture is a profession. To such a query, when addressed to us, as it has been more than once, we have emphatically replied in the affirmative. At the same time we cannot help feeling that in the increasing development of the trade element in architectural practice there is much that is calculated to inspire a contrary belief. If we take the profession as a whole we shall find it made up of two distinct classes (1) those who reduce architecture to the dead level of a means of livelihood, and (2) those who live for, as well as by, their art.

To the first-named class belong all the attributes of the commercial speculator, with identically the same motives. Their success in life depends on their general capacity for business rather than upon any intimate acquaintance with the art of the profession into which they have inducted themselves. If, by any means, they can secure a fair modicum of clients, their course is tolerably easy. The accomplishment of the work devolves upon the clever assistants and competent foremen with whom the architect-tradesman is shrewd enough to surround himself. Now, it is this class of "architects" who have developed the trade element in the architectural profession to its present inordinate degree, and which we cannot but regard as damaging to the status of the profession and obstructive to its art. The close assimilation of the art of architecture with the business of building renders the introduction of this trade element comparatively easy, and all the more insidious in its growth. A knowledge of the latter by no means implies the ability to practice the former, yet how often does not this theory find actual exemplification?

In many ways well known to our Friends in Council, and also to our readers generally, does this trade element disclose itself; but its nursery is undoubtedly amongst the class of men who prostitute architecture to the mere pursuit of mercenary ends.

Wherein shall we find the remedy? Surely in a united and concentrated effort to raise the status of the profession beyond the reach of all future intruding "speculators." The character of a "profession" and its right to the dignity of such a title is determined by the qualifications of its individual constituents for the legitimate practice of that profession. In the professions of law and medicine there are practically no charlatans or quacks; in the architectural profession their name is legion. To rid our profession of these is a duty we owe no less to ourselves than to our art, and our hope lies rather in measures that shall prevent their future admission than in ousting those already established. It ought to be impossible for a brass plate to constitute a sufficient diploma for a man to set up as a qualified architect.

We have raised the standard of the Institute examinations, and we have done much in the establishment of educational classes in connection with our metropolitan and provincial associations. But what of the many practices which now obtain in the profession, and which not only merit censure, but deserve total abolition? The Institute has talked, and it has rebuked offenders, but what has it *done?* The offenders may sever their connection with the Institute, but they continue practicing all the same. In the law profession, if any member of it is found guilty of conduct unbecoming the status of a gentleman and of the profession, he is not only cut off from membership, but his profession knows him no more. A barrister, though he may remain briefless for the whole term of his natural life, is not permitted to solicit briefs; he has simply to wait. But an architect may advertise himself right and left (and does); he may "tout," and use every influence, direct and indirect; yet it is not deemed an undignified thing to do; and, trade-manlike, he reaps his reward. This practice itself must, as we urged long ago, have a material influence on the status of the profession, and there is no disguising the fact that it is one of those trade elements which tend to the lowering of such status, and incline school boards and other public bodies to find out, by advertisement, for *how little per cent.* an architect can be found to work.

Is it not time this trading spirit, so surely developing to the hurt of the profession at large, was checked, if not entirely stopped? The evil is widespread, and therefore the more dangerous. The question of a remedy for it is, we maintain, a personal one—personal as it concerns the welfare of our art, and personal as it affects the professional status of each individual who practices it. To put down those practices which are detrimental to the best interests of the profession requires not an individual outcry, or a single bright example, but a strong, united protest, and earnest, concerted action; it is for this we appeal. Then, in a profession purified of the abuses which have been allowed to creep in during these latter days, we may hope to see less of that trading spirit which now animates so large a section of our profession, and more of that spirit which has Art as the source of its inspiration. So shall we emulate the master-spirit which should be the mainspring of all our work, and of which Carlyle wrote: "Thou canst not hire him by thy guineas; nor by thy gibbets and law penalties restrain him. Thou canst not forward him; thou canst not hinder him. Thy penalties, thy poverties, neglects, contumelies. Behold, all these are good for him!"

ARCHITECT.

WE are told that Solomon's Temple at Jerusalem cost over seventy-seven millions of dollars complete. There were evidently Government contractors in those days.

GUN cotton is insoluble in water, being unaffected even by long soaking. Strong sulphuric acid dissolves it with some difficulty.

Bound volumes of 1883 now ready. Price $2.50.

Oils and Driers.

IT is very necessary that the painter should know something about the oil he uses, as well as the pigments. It is apparent to every one that has used linseed oil that, as it dries, it undergoes certain changes. One authority computes that on the average linseed oil paint or varnish takes about three months to dry. As the oil grows harder it protects itself against the air—that is to say, its surface prevents the air from getting at the oil underneath the surface. It assumes the character of a solid hard leather, which contracts in drying and pulls itself together; the effect of this pulling or contracting is to produce cracks. The contraction of oil in becoming hard, and its sudden contraction under cold, are the chief causes of the difficulty experienced in varnishing. Varnish and oil usually crack in a direction across the grain of the wood, the chief reason of which is that wood does not contract in its length, and therefore the varnish in contracting cracks. Mr. C. L. Conder, in his useful book on painters' materials, observes that "oil dried in the sunlight and exposed to the direct rays will not last nearly as long as oil in the shade. Painters assert that oil dried in the coldest weather lasts the longest; it is difficult to see why this should be so, unless on account of the small loss of not-drying oil. When the oil is dry, or hard, the loss of not-drying oil goes on very slowly." We must refer the reader to the work of Mr Conder for an examination of the causes of cracking; suffice it to observe that all painters are aware that too thick a coat or too many oil coats in one painting will cause cracking. Speaking of driers or "siccatives," which have an important bearing upon the subject, Muckley says that gum mastic, in the mediums used by English artists, has been a great injury to their pictures, and recommends copal varnish as the best drier. Others find the siccative of Harlem, made with gums, of value; but copal was largely used as a medium by the old masters. Driers harden the oil by turning it into soap; but this also may be destructive if the oil is made too hard.—*Building News.*

The "Columbus" Wrought Steel Kitchen.

THESE sinks are entirely new, being stamped from one plate of steel and superior to cast iron sinks in every particular, being lighter, stronger, and more durable.

Being made of *wrought steel* they will not break from heat, cold, or any cause whatever.

Prices range from $1.80 each for 16x24x6 size, to $4.00 for 20x40x6 size.

Richards & Snow, 406 and 408 Market St., are agents on this coast for these sinks.

THE temperature at which dry-rot of timber proceeds most rapidly is 80° F.

We cannot supply single numbers complete for the year 1881. A few bound volumes of that year can be had for $2.50 each.

Thomas J. Welsh.

THE subject of this sketch may be justly termed a Californian, for, although born in Australia in 1845, his advent on this coast occurred when he was but a child. The Junior Editor of this Journal can speak from personal knowledge of Mr. Welsh's career, as each attended the same school, and for many years their paths of study and duty lay in the same general direction.

During the whole course of study, through all the gradations from primary to high school, Mr. Welsh's career was marked by an earnest thoughtfulness coupled with an anxious desire to excel. His especial attention was given to geometry, history, and the natural sciences. The principles of the first study he early mastered, and the benefit therefrom can be seen in the ease with which to-day he masters the intricate problems so often met in the practice of his profession. His love for history led him to study the monuments of ancient Rome, Greece, Carthage, and Egypt, and the record of the architectural ability there displayed.

Passing from school life, we next find Mr. Welsh engaged in mastering the *practical* part of his chosen profession. Under the instruction and guidance of some of the master builders of the times, he early became proficient as a mechanic.

(We may be pardoned for making a little digression here. Many of the more prominent architects—both in the present and in the past—are, and were those who have thoroughly mastered the building trade while young. Most of the prominent architects now practicing their profession in this city, are those who have first become conversant, in a practical way, with the saw, jack plane, and trowel.)

His course of mechanical study being completed, Mr. Welsh next engaged in office duties. Under such instructors as Messrs. Farquharson, Kenitzer, and George Bordwell, he made rapid strides in the study of Architecture. In 1872 he commenced business for himself in his present location, and his success has been very flattering to himself as well as to his friends.

The earnestness in every study which marked Mr. Welsh's scholastic career, is still evidenced in the works of his later life. Many of our churches owe their architectural beauty to his thoughtful study and skill. Some of the finest monuments and memorial tablets now gracing Calvary and other cemeteries are the result of his ability. Many of our private dwellings—from the costly mansion to the humble abode of the mechanic—have been planned and erected under the same superintendence.

During the past year Mr. Welsh was elected Architect of the School Department of San Francisco, a position which he now holds. He is also President of the San Francisco Mutual Building and Loan Society, a member of the San Francisco Chapter, also a Fellow of the American Institute of Architects. In each of these, the duties involved upon him, whether as member or officer, are attended to with earnestness and a general endeavor to advance the interests of all concerned.

THOMAS J. WELSH.

During one term Mr. Welsh was Treasurer of the San Francisco Chapter. In all his dealings with the Chapter as a body, and the individual members thereof, Mr. Welsh has endeavored to carry out ideas of professional courtesy among his architectural brethren, and to sustain a dignity and harmony of action that should always characterize men in artistic callings.

METHYL alcohol, or wood naphtha, is an alcohol obtained as one of the products of the destructive distillation of wood.

The Demand for Skill.

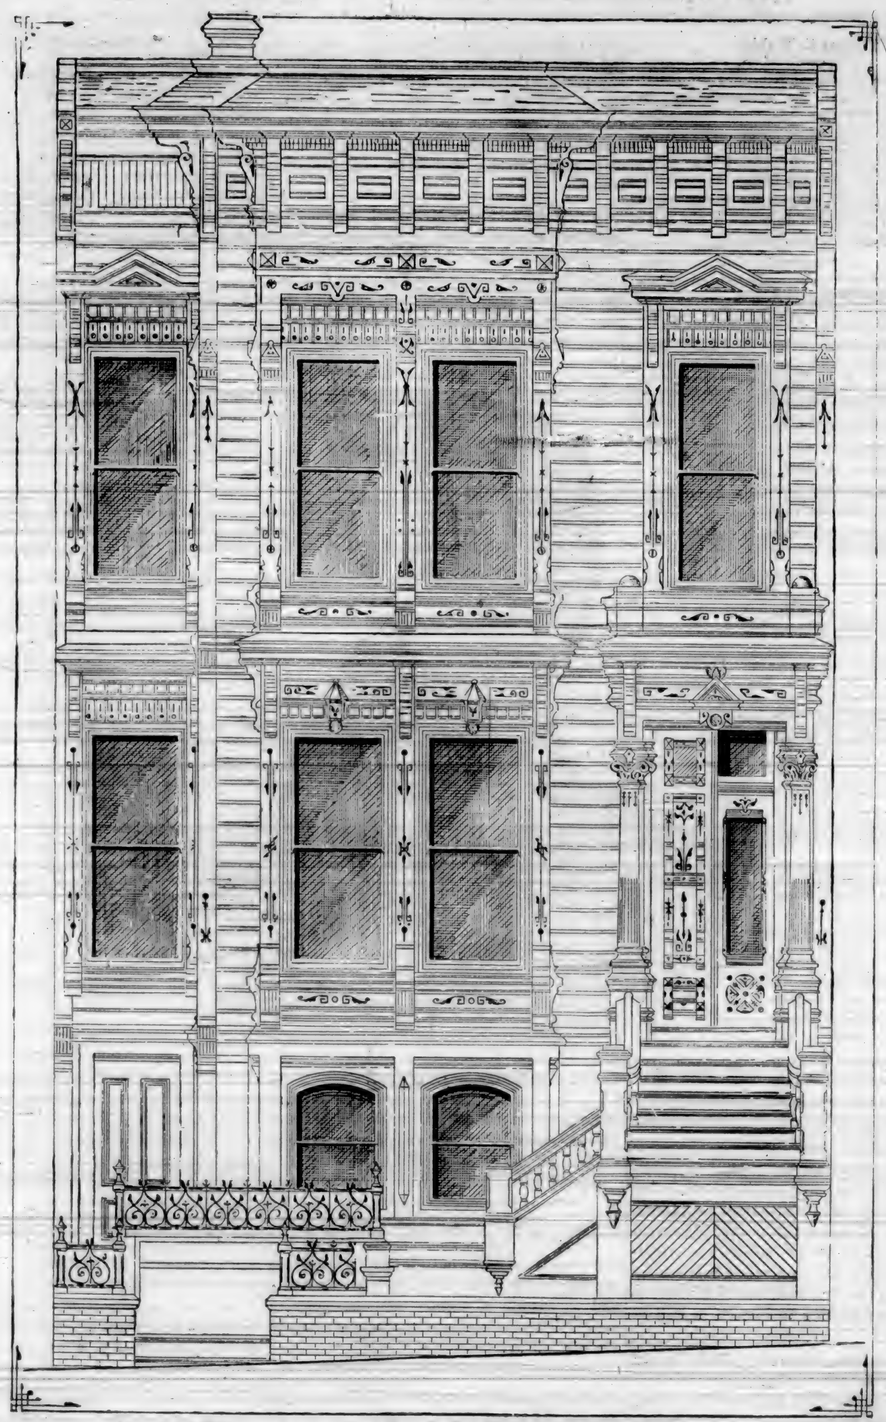
NOTWITHSTANDING the present slackness in business, there is a demand for skill in the mechanic arts now, as there usually is. The proprietor of a manufactory of machine tools recently supplemented a jeremiad on the dullness of the times by an inquiry for several first-class workmen. In explanation he said he had more than he needed of the qualities of "main strength and stupidity" in his establishment, but still had room for cultivated eyes and hands guided by judgment; in short, skilled workmen were in demand.

There is reason for this condition of affairs. The more nearly absolutely automatic machinery can be made, and the more exact hand tools and appliances can be made, the more exacting are the demands for personal skill and judgment. Machines are made, they do not grow, and they are made by the intelligent and skillful mechanic. They will not even keep in useful operation and continue in useful life except by constant care and the oversight of the skilled mechanic.

The time has passed when the idea of working materials was to hammer and bang them into shape somehow, with crude tools and cruder appliances. In the case of the metals especially, the workman uses good judgment with fine tools. No finer work is done and no more perfect results are obtained in any department of human production than in that of the working of metals, and to accomplish such results the most exact of tools must be wielded and guided by the most skillful hands and the most careful judgment.—*Scientific American.*

PAPERHANGER'S PASTE.—First heat water to boiling, then add flour, with constant stirring. To prevent the formation of lumps the flour may be passed through a sieve, so as to ensure it more equable distribution. Agitation is continued until the heat has rendered the mass of the desired consistency, and, after a few moments' further boiling, it is ready for use. In order to increase its strength, powdered resin in proportion of one-sixth to one-fourth of the weight of the flour is added. To prevent its souring, oil of cloves or a few drops of carbolic acid are added.

CARPETS are now being made from paper.



ELEVATION FOR CITY RESIDENCE COSTING ABOUT $7,500.

"Architectural Competitions in General and the Pioneers' Competative Plans in Particular."

A PAPER read before the San Francisco Chapter, A. I. A., on Saturday evening, Feb. 9, 1884, by Horace Greeley Knapp, late of New York.

Mr. President and fellow-members of the American Institute of Architects: With your kind fraternal courtesy I gladly avail myself of the present opportunity of submitting to your consideration a few thoughts and ideas on the subject which you have assembled this evening to discuss, namely, "Architectural competitions in general and the Pioneers' competitive plans in particular."

With a due regard to the limited time at your command for the business of the evening, I shall be very brief, touching only upon such points and features of the subject as are, I trust, especially suited to the occasion and as may be most worthy of your attention.

The subject of architectural competitions is unquestionably one of the most vital and formidable problems that is now presented to the architects of this country, and so long as a due appreciation of its importance and its true relations to the profession and the public is not established, so long will the master art have but a languid vitality and the domain of true architecture be usurped by the aberrations of incompetent tyros. Well-conducted competitions may possess certain apparent advantages to both architect and client, but these seeming advantages are so unreal or insignificant compared with the inevitable evils by which they are attended and offset, that many of our best architects, those whose lives and whole energies are devoted to advance the art and sustain the dignity of the profession, are beginning to hold aloof from all competitions as being baneful in their tendency and dishonorable in their requirements. *All* architectual competitions are thus deprived of some of the best skill and talent in the profession, and *many*, by the peculiar conditions imposed, engage only the worst. In the latter event, which under the present system will soon become the rule rather than the exception, the client and the public are forced to accept the most worthless productions, and respectable architecture is judged by this miserable criterion. And herein lies the chief source of the discouraging impediments to architectural progress in the United States. The demand for superior work must arise with the public. The tendency of unrestricted competitions is to corrupt and vitiate public taste and bring the noblest of all professions into contempt. There is no profession in which the highest degree of thorough proficiency and skill is attained by such assiduous toil and study, and there is no other profession that is subjected to such beggarly humiliations. Since arriving in San Francisco, I have received from a well-known physician in New York, a letter, which, together with my reply, may be of interest. The doctor writes as follows:

"MR. H. G. KNAPP—*My Dear Sir:* I wish to procure and consider plans for a suburban residence, which I intend to build in the 23d Ward, this spring. If you wish to submit one of your designs in competition with other architects, I shall be glad to send you full particulars.

Truly yours, etc."

To this I sent the following reply:

DR. ——, *Dear Sir:* In reply to your favor of the 18th ultimo, I would say that I must decline your kind offer. By way of reciprocating your generous intentions, I beg to advise you that I am suffering with a severe cold, and have concluded to have it cured sometime between this and spring. Should you wish to tender your services in competition with several other physicians, I shall be pleased to receive and examine your prescriptions. Etc. To save time I will state that the terms and conditions of the competition are as follows: The dimensions of the cold, upon which you are to exercise your best skill, are very great, and must be determined accurately by the competing physicians. It was perhaps contracted by exposure to climatic changes, but this you are to ascertain by careful diagnosis and a detailed analysis of all matter bearing upon the subject. Your conclusions, in the form of a voluminous treatise on the subject, in the preparation of which you shall have expended at least two weeks labor, must accompany your prescriptions. The prescriptions will be submitted to the examination of a drug clerk, who will be required to vouch for their wholesomeness and efficacy. Physicians will also tender proposals naming the amount for which they will cure the said cold in case their views and suggestions meet the patient's approval and their nostrums are favorably reported by the drug clerk. The patient reserves the right to reject any and all medical services after the same shall have been rendered.

Very truly yours, etc."

Now, to the professional physician, the foregoing proposition could only be regarded as a ludicrous joke. Yet this is a fair example of much of the condescending patronage with which the *architect* is favored, and so long as these indignities are tolerated and encouraged by the profession, the public will have little desire and feeling for the art, and little respect for its practitioners. When professional practice has been reduced to a mad scramble after the naked bone which is generally offered as a competition prize, architects lose all self-respect, and entirely forget the courtesies that are due to their professional brethren.

When we consider the lavish waste of labor involved in architectural competitions, and which falls entirely upon the profession, we are amazed at its magnitude, and we might well seek to destroy this parasite that has so effectually sapped our practice of its virtue and vitality. A recent competition in New York brought in over two hundred designs, not one of which met the given requirements as fully and intelligently as might have been done by any skillful architect who could command the advantages of constant verbal intercourse with his client, and who was not hampered and hedged in by the unwise restrictions of the circular of instructions.

About four years ago Mr. Thomas Porter, a Fellow of the Royal Institute of British Architects gave to the Institute some very interesting statistics of the number and enormous cost of competitions in England. After careful analysis of all the competitions advertised for two and a half years, he found that the average annual cost of competitive drawings was $125,000, and this enormous sum only represented, not the actual value of the drawings, but the mere cost of preparing them, making no allowance for the time and labor of the architects themselves, who submitted them.

If this is the situation in England, where the profession commands prerogatives and a general respect, which is denied it here, we need not wonder that with this vast and perpetual waste of energy and substance, American architects are prone to employ unprofessional expedients to recompense their losses, and that building committees are frequently captured by *ad captandam* artifice.

Competitions must be accepted, however, as a necessary evil, the fruits of which fall alike to the architect and the client, and the question with us is not, How can they be abolished? but, How can they be properly regulated? There is, to my mind, but one practicable method, and that is the general adoption by the leading architects of the United States of a carefully considered schedule of terms. This has already been done by the St. Louis architects, and resolutions affecting members engaging in competitions were passed by the Institute in 1878.

Without attempting to suggest the regulations in detail by which architects should be governed in open competitions, I will briefly offer the following hints for a general schedule of terms.

The amount of the premiums should, in the aggregate, be equal to the amount to which an architect would be entitled for such work were there no competition.

The author of the first premiated design to be employed to take charge of the work at the rate of compensation established by the American Institute of Architects.

The designs to be submitted to a jury, one member of which shall be an architect of acknowledged ability who is not directly or indirectly interested in the competition.

All the designs, excepting the one adopted, to be returned to their respective authors.

A definite date to be fixed for final judgment on the designs submitted, and the decision to be announced and the rejected designs returned on that day.

Regarding the Pioneers competitive designs, I am perhaps not so well qualified to express an opinion as yourselves, being a comparative stranger in San Francisco. I am impressed with the feeling, however, that the committee, in fixing their terms and conditions, have been governed by local precedent, and their best judgment based on the existing public estimate of matters architectural. They have, at least, made some little gracious concessions, having, in their amended circular, eliminated two very objectionable paragraphs.

Personally, I would say that, having entered this new and inviting field in response to the demands of my wife's health, I must confess the temptation to embrace any just and honorable opportunity for establishing my practice in so pleasant and promising a clime. I shall therefore await the result of your deliberations with interest.

Lumber Receipts in 1883.

THE Secretary of the California Lumber Exchange has furnished us with the following statement of the amount of lumber, etc., received in this city during the past year. It will prove interesting in comparison with other cities.

Special Meeting San Francisco Chapter.

A SPECIAL meeting of the San Francisco Chapter was held on Saturday evening, February 9th, to consider "Architectural Competitions in General and the Pioneers in Particular."

A large attendance was present. The President, John Wright, in the Chair.

The committee appointed at the last regular meeting to wait on the Building Committee of the Pioneers, reported as follows:—

SAN FRANCISCO, February 4, 1884.

THE San Francisco Chapter of the American Institute of Architects respectfully submit the following modifications to the Building Committee of the Pioneer's Hall Association in their circular addressed to architects, inviting them to compete for the proposed new building of the said association:—

1. That the drawings shall all be of a uniform scale of one-eighth inch per foot, and shall consist of a plan of each story, including basement, a roof plan, two sections, and two elevations. No colored drawings or perspectives to be considered. The plans and sections be colored to indicate the style of construction.

2. That the value of the premiums shall be increased on account of the great amount of work necessary to make complete plans. The increase in the value of the premiums will benefit the society inasmuch as it will insure a larger number and a better class of competitors.

3. That the premiums be paid in all cases, and be considered as a reward for the most meritorious design, and be not deducted from the amount of commission.

4. That the clause relating to a guarantee by contractors of the architect's estimate be stricken out.

5. Considering that the plans chosen will be the ones which will best answer the requirements of the society, and that the matter relating to the architect's commission would be only of a secondary consideration compared with the merit of the design, we desire that the clause implying a degrading underbidding from professional men be stricken out.

[Signed.] JOHN WRIGHT,
ALBERT PISSIS,
Com. Mittee.

The report was received and committee discharged. An interesting paper was read by H. G. Knapp, which was ordered printed in full in the official organ. (It will be found in another column.)

Mr. Pissis offered the following:—

Resolved, That the Chapter disapprove of the present competition, as the terms are unjust and the premiums insufficient.

After a long debate the resolution was unanimously carried.

The following resolution was presented:—

Resolved, That in future no competition shall be entered into by any member of this Chapter, unless the terms are in accordance with rules to be made by a committee, and these rules be approved by the Chapter, said committee to be appointed at next meeting.

Amended so that the committee shall consist of five Fellows, whose duty it will be to take into consideration the whole subject matter, and also to take cognizance of the above resolution, the committee to be appointed by the President.

Messrs. Pissis, Chairman; J. E. Wolfe, Curlett, Macy, and Gash were appointed to act as such committee.

Adjourned.

Some of the Objectionable Features Contained in the Circular to Architects for Plans, Specifications, and Estimates for Pioneer Building.

THE first part of the pamphlet contains a description of a building to cost about $150,000; all modern conveniences generally found in buildings of like cost, are to be placed in the one under consideration.

. . . . . .

"The committee will receive, examine, and consider all plans, specifications, and estimates so presented to them, and will select therefrom—subject to the modifications hereinafter named—the three which, in their judgment, seem nearest to meeting their requirements, returning all the others to the respective architects submitting them. The three so selected will be carefully considered and passed upon by the committee. For the plans, specifications, and estimates which most nearly meet the committee's requirements, they will pay the sum of $500. For the next in order considered from the same standpoint, they will pay $300, and for the next $150, retaining all three as the property of the society.

"*The committe reserve to themselves the right to reject any and all plans.*

"It is distinctly understood that the committee incur no responsibility, either for themselves or the society, for any plans, specifications, and estimates other than the three to be selected as hereinbefore set forth, all the others being at the disposal of the parties submitting them, without any cost whatever to the committee or the Society of California Pioneers.

"It is further understood that all estimates furnished by architects shall be indorsed by some well-known contractor or contractors, with the proviso that such contractor or contractors are willing to contract for the erection and completion of such building for the amount named in such estimates.

"*Architects competing will advise the committee when their plans are submitted what their professional charges will be in case their plans are adopted by the committee, and approved by the Board of Directors.* The plans for which the first premium of $500 is to be paid, if adopted by the committee, and approved by the Board of Directors as those from which the building will be constructed, will be subject to the condition that the premium will be considered part of the architect's professional charges, and will be deducted therefrom in final settlement."

LEBANON, Pa., Jan. 23, 1884.

GENTLEMEN:—In your issue for January, you publish a copyrighted design for a cresting. Wherein does the patent exist? An answer will greatly oblige a subscriber.

Yours, etc.,
HARVEY T. HAUER.

In the simple fact that it is *new and original in its design*. Neither fruits, flowers, leaves, nor any other thing produced by the laws of growth in nature, can be copyrighted *as such*, but in special combination, expressing or delineating *originality of conception* in the thing produced, even by the use and application of things and forms in nature not in themselves entitled to protection under the law in such cases made and provided,—the parties producing can claim exclusive right and find protection from infringement by copyright.

To the San Francisco Chapter.

I AM an old and decrepit pioneer. I also belong to the Independent Order of Odd Fellows. I do not feel as well and as hearty as I did thirty years ago. I might describe my symptoms and the causes which broke down my constitution, but I would rather not; respect my silence.

Three of our most eminent physicians have examined me thoroughly, and their opinions as to the manner of curing my numerous infirmities vary.

I take this occasion to thank them sincerely, and I earnestly hope they understand that, as I have not as yet adopted the modes of treatment which they advised, they shall not send me any bills for medical services.

Through their courtesy I know that I am suffering from a severe attack of the gout, and that my kidneys are badly affected.

Alas! alas! how I regret the follies of my youth; but it is useless to weep. Let us endeavor to recover our health.

Some treatments are long and tedious. Perhaps some physician may have discovered some new remedy which will exactly suit my case.

Let us open a competition. I have been advised to do so.

The terms under which I invite competitive medical consultation and prescriptions are as follows:—

1. I must be restored to perfect health.

2. The treatment must be short, pleasant, and convenient to follow.

3. The maximum cost of doctor's fees and medicine must not exceed fifteen dollars. I will receive, examine, and consider all prescriptions and suggestions, subject to modifications hereinafter named. The three manners of treatment which in my judgment best suit my dilapidated condition, will be selected and passed upon. For the prescription I prefer, I will pay the sum of fifty cents. For the next in order considered from the same standpoint, I will pay thirty cents, and for the next, fifteen cents, retaining all three as my property with the right to use them if I see fit. I reserve myself the right to reject any or all prescriptions.

It is distinctly understood that I will incur no responsibility either for myself or for my family, for any written consultation or prescriptions other than the three selected as hereinbefore set forth, all the others being at the disposal of the parties submitting them, without any cost whatever to myself or my family.

It is further understood that all estimates as to the cost of medicines shall be indorsed by some well-known druggist or druggists, with the proviso that such druggist or druggists are willing to contract for the furnishing of such medicines as are prescribed, for the amount of the estimated cost.

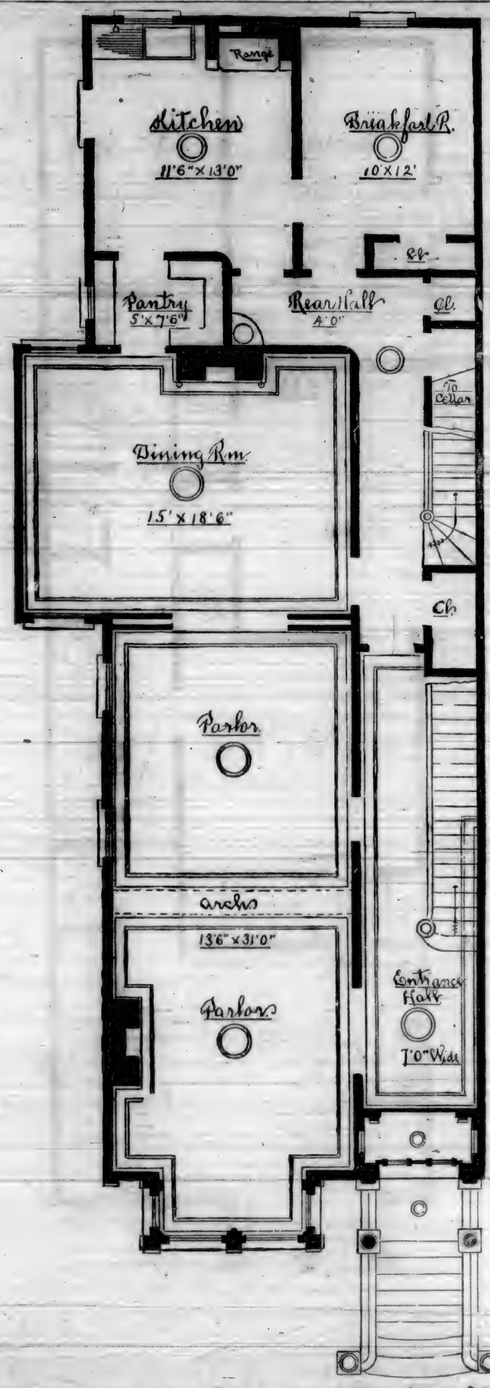
Physicians competing will advise me as to what their professional charges will be in case their prescription and mode of treatment are accepted by me and approved by my family.

The consultation for which the first payment of fifty cents is to be paid, if adopted by me and approved by my family as the one by which I am to be treated, will be subject to the condition that the premium of fifty cents will be considered as part of the physician's professional charges, and will be deducted therefrom in final settlement.

All written consultations, prescriptions, and suggestions must be sent to me on or before March 25, 1884.

AGED PIONEER AND ODD FELLOW.

"Lumberman's Hand Book." Price, $2.00.



FIRST FLOOR PLAN CITY RESIDENCE, COSTING ABOUT $7,500.

Competition Plans for Pioneer Building.

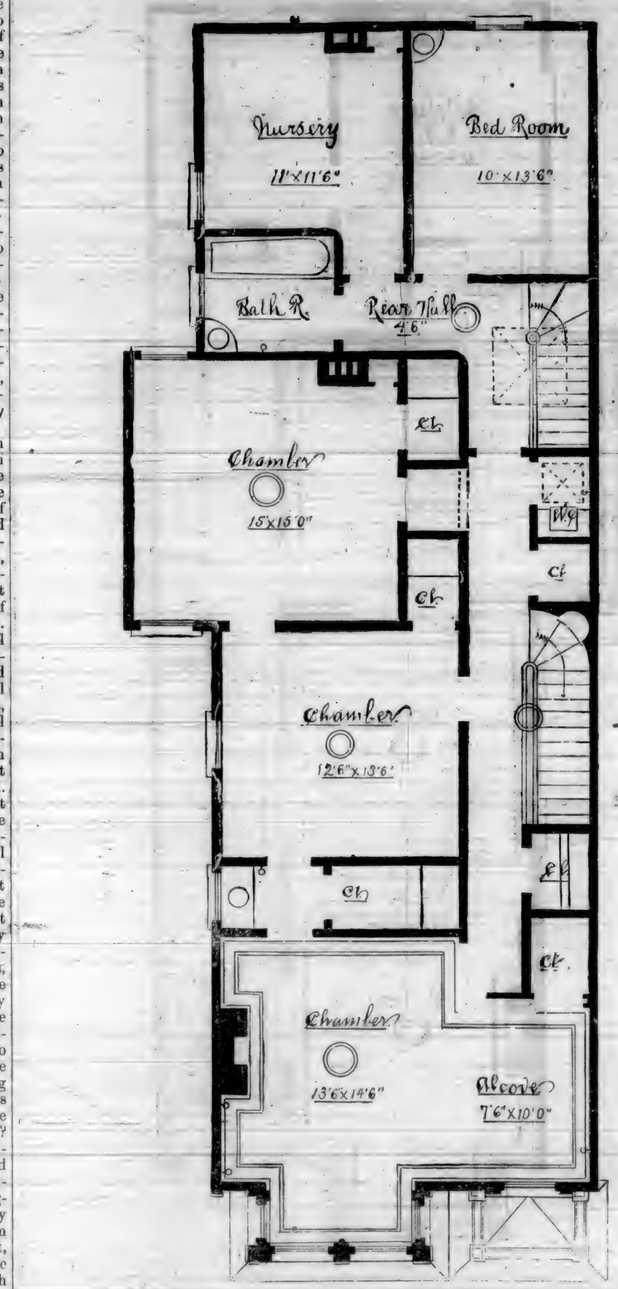
THE Society of California "Pioneers," having determined to proceed with the erection of a building on their splendid gift property on Fourth Street, have appointed a committee of five gentlemen, well known in San Francisco as to their business qualifications and intelligence in matters generally, within the circle of their experiences and information, to procure plans. But unfortunately for themselves and architects generally, as a committee, they have developed either a total incompetency for the duties placed upon them, and a lack of correct understanding as to the rights of architects, and the value of architectural services, or an indifference and disregard of every principle of right, justice, and fairness toward an honorable profession, which, upon the high order of merit due to the honorable and competent of its members, deserves far better recognition.

The fact that gross wrongs have been imposed upon architects in other cases, and architects have meanly allowed themselves to be badly used, by submitting to iniquitous exactions upon delusive, uncertain, and frequently fraudulent pretenses, is at least not a *generous* basis for men of just and fair minds and honest and equitable purposes to act. This *cornering* system of competitions, shutting the door against all good and competent men, or compelling them to compete upon a non-paying basis to any except the *one man* who secures its first premium and superintendence, is in no sense or respect right or just. In the present case, the sum of $950 is offered as premiums for *three* preferred sets of plans, specifications, estimates, etc., much less than the value of a *single set*, as measured by all architectural societies and Chapters the civilized world over. Yet should twenty architects be silly enough to engage in the contest, the collective aggregate cost *in coin*, allowing that the delineation work is all done by skillful and competent, paid draughtsmen, will not be less than $6,000, to say nothing of the time, skill, judgment, etc., of the principal, the time occupied in writing specifications, preparing estimates, etc., and the expense of office rent, paper and other things, all of which considered by honest and equitable valuation would reach a total sum of fully $10,000—for all of which the *grand total*(!) of $950 to *three* of the twenty is the *ultimatum*, leaving the loss of the remaining $9,050 as a sweet morsel for the seventeen rejected simpletons to feast up.

The first "circular" issued by the committee contained "terms and conditions" which were so manifestly wrong in every sense that the Chapter of Architects assembled February 1st, gave emphatic expression to the general feeling of disapprobation entertained by every honorable and intelligent member of the profession upon the Pacific Coast. We say this knowingly and understandingly. The Chapter, at said session, appointed a Conference Committee to meet the five gentlemen representing the Pioneer Society, but before an interview was reached between the committees, a second, modified form of circular had been issued, removing some and retaining other of the objectionable conditions. The omissions in the amended documents are: *first*, the claim which requires that architects should back up their estimates of cost by the indorsements of some competent and responsible contractor who would be willing to complete the building at the stipulated cost. This proposition simply and more fully exposes, at least, the *thoughtlessness* of the committee, for had each estimate been so accompanied, that accompaniment would have possessed an intrinsic cost value of $100 each, or a total of $2,000, which, if paid for by the architects, would

have increased the amount of loss to the defeated seventeen, of $1,700, which added to the $9.050 would have raised the amount of actual loss to $10.750. Or, if not paid for, the loss of the $1,700 would have fallen upon contractors. The second omission made is in vacating the charge of first premium amount against and deducting the same from the "architects' professional charges" at settlement. Also, that of requiring architects to bid for the job by stating the percentage rates each would require for his services, less than the established rates. The committee, however, retain in the amended circular that *exceedingly obnoxious, unreasonable, and inequitable condition* of "reserve the right to reject any or all plans." But the bad features of the issue are so numerous and vexatious that it would consume more than the entire pages of our issue to notice them in detail. The 1882 volume of this Journal contains six articles upon the subject of competitions, which would improve the understanding of the committee amazingly. The $950, nor any part thereof, as premium, is a certainty, as the "reserve" is fatal to *certainty* if put in practice.

The Society has had the matter of plans in hand for several years, and plans have been made and submitted. This fact argues the folly of all others to compete against those who have so long had the ear and confidence of the society, and who have so much greater and better information to act upon than is contained in the circular. Whatever loss in time, labor, and money to others, that loss is promoted by the acts and inducements held out by the committee, for the special benefit of themselves and the society they represent. Taken as a whole, with very few and small exceptions, statements and assurances pledging that "the competition will be honestly and honorably conducted," "that the awards will be determined upon fair and equitable grounds, without preference or favor to any," is all well in poetry, but fearfully deceiving and misleading in fact; for as an underlying, well proven fact, such competitions are a something that does not occur ten, if five times in a hundred. This is a strong statement, but we make it boldly because we know the fact, and are able to conclusively verify the same whenever necessary, by a line of testimony which cannot fail to carry conclusive conviction to every unprejudiced mind, although the *legal* proof might be lacking in some cases. As another feature of unpardonable injustice and wrong, is that of indiscriminate competition, which is likely to set to work one-half or more of the competing parties, who upon merit, qualifications, and reputation, would be discarded by the committee, if their names were seriously proposed in the premises, as architects of the building. Is it then a proper course for honorable men to pursue to inveigle others into expense and loss, who possess not a single chance, not one in one thousand of securing the first award, however meritorious their plans might be? Is it a right and sufficient excuse to urge a lack of knowledge as to such parties? To seek to excuse the wrong by pleading non-intent? If the committee had known and desired to do the right thing toward all competitors, they would have selected five recognized, competent, skillful, and trustworthy architects, confining the competition to them exclusively, and giving to each and all right, reasonable, and sufficient competition for the services required. We close this article with a notice of the fact that the generous donor of the property and funds involved in this case, in the contemplation of building improvements during his lifetime, relied upon his own judgment as to the qualifications and integrity of architects, and engaged singly those who he was willing to trust, without huxtering the market to secure competitive plans at heavy cost and loss to others, and no special benefit to any; for under any circumstances only one man as an architect profits by the erection of a building. A following of the example of the generous dead would have saved the committee the expense and annoyances attending their "circular to architects."



SECOND FLOOR PLAN CITY RESIDENCE, COSTING ABOUT $7,500.

The San Francisco Chapter of Architects—Its Aims and Its Objects.

NUMBER TWO.

THE formation of the Pacific Coast Association of Architects was not the result of a sudden impulse. Months before the call was made for its organization, a few earnest workers were canvassing the field, making inquiries here and there for the purpose of ascertaining how many of the architects would be willing to lend their aid to a permanent association.

When the call was made for a general meeting, the largest number of architects ever assembled together in this city at one time met in a room at the Mechanics' Institute. Mr. A. Laver was chosen President. Twenty-nine signed the roll—a splendid beginning surely; and to the credit of the original twenty-nine, nearly every one has continued up to date through Association and Chapter, in full membership.

The first six months was rather up-hill work, being of necessity rather prosy in its character. By-laws that would stand the criticism, and yet receive the commendation of their professional brethren in the East, had to be framed and adopted. This work fell into the hands of those well qualified to perform that duty, and the code presented gave general satisfaction.

Not satisfied with a local organization, as an "Association," steps were taken to form a Chapter of the American Institute. The President being the only member of that body on this coast, it was through his efforts that six prominent architects became members of the Parent Institution, and thus formed the basis for a Chapter on this Coast.

Since its organization San Francisco Chapter has progressed finely in the accomplishment of the aims and objects for which it was started, and to-day it is one of the largest in the United States. Its meetings have been fairly attended, averaging about twenty; a full record of its proceedings is given in the columns of this Journal. Below will be found a full list of the officers and members of the Chapter in good standing.

JOHN WRIGHT, *President.*
WM. CURLETT, *Vice-President.*

WARREN H. WILLIAMS, Portland.

MANY portable mills have been set up in the woods of Maine for the purpose of working up the timber blown down by the winds last season. An unusual number of trees were thus prostrated.

Bound volumes of 1883 now ready. Price $2.50.

A CHEAP clock may be made to appear very attractive in this way—take two cigar boxes, cut a hole in one just the size of the face of the clock, and tack it securely endwise on the top of the other box, which, of course, is in its natural horizontal position. Cover them both with garnet plush or velvet, glued smoothly to the wood, and fasten the clock with strong wire inside the upper box, to show only the face, as if in a frame. Screw four brass knobs under the lower box as feet for it to rest on, and make a little railing around it of a miniature brass chain upheld by gilt-headed millinery pins. The top of the upper box should be finished in the same manner. The effect is excellent.

SAVE the tea leaves for a few days, then steep them in a tin pail or pan for half an hour; strain through a sieve and use the tea for all varnished paints. It requires very little elbow polish, as the tea acts as a strong detergent, cleansing the paint from all impurities, and making it equal to new. It cleans windows, and sashes, and oil cloths—indeed, any varnished surface is improved by its application. It washes window panes and mirrors much better than water, and is excellent for cleaning black walnut and looking-glass frames. It will not do to wash unvarnished paints with it.

THERE is nothing so tends to shorten the lives of old people, and to injure their health, as the practice of sitting up late, particularly winter evenings. This is especially the case where the e is a grown-up daughter in the family. This sanitary item is published at the request of several young men.

WREN, the architect of St. Paul's, designed more than forty public buildings in London.

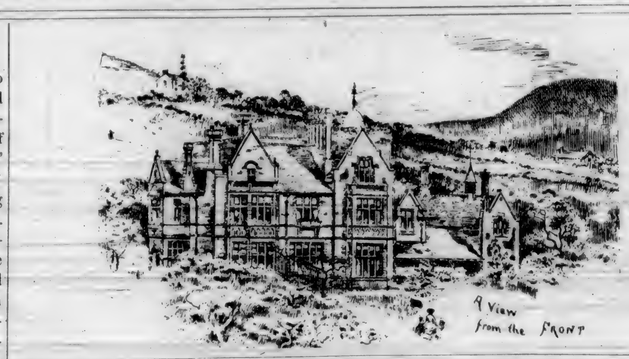
Repeal of the Duty on Imported Lumber.

"SAN FRANCISCO lumbermen are opposed to the repeal of the lumber duty. What would materially benefit the Eastern States would injure them. This is a practical illustration of the difficulty in the way of tariff reform." —*Evening Post.*

It is perfectly natural that this feeling should exist in the lumber combination monopoly of San Francisco, and among its members individually; for if the barriers were removed so as to open a ready market, and encourage the manufacture of lumber within the domain of her Majesty's possessions adjacent to the waters of Puget Sounds, the unreasonably high prices from time to time and at the present exacted for all classes of lumber material in California, could not be maintained; for it is not at all probable that the present California and Puget Sound lumber kings would be able to control the prices of lumber manufacture on the British side of the lines. Hence it is bread and butter, or rather bags of gold to the combination to have the tariff duties on imported lumber continued, and if need be increased. No better proof need be desired that the controlling—the manufacturing portion of the monopoly conclave—are massing great wealth rapidly, at the expense of the general public, than the fact that the boast is freely indulged in by representations of the lumber trade, of their firms having accumulated hundreds of thousands of dollars, since the revival of business in 1880, and the *increase of prices* of lumber materials.

While we wish no ill to the American manufacturers and dealers, there are reasons why —personally—we should like to see the doors opened, which would permit the importation of British Columbia lumber into California upon fair and reasonable terms. We do not advocate the abandonment of all tariff restrictions, but such modifications as would secure right, proper, and healthful competitions,—such as would pay a fair,—even liberal return for the money invested, and sufficient to cover all contingent risks; and at the same time give to owners of real estate equal protection from the payment of very much more than fair, just, and reasonable prices for lumber.

Again, we should like to see a supply of British manufactured lumber in the markets of California, because their standards of measurement are full and honest, in contrast with the abominable, unpardonable, and not intrinsically honest American standard. By the American scale of inches, when one buys and pays for dressed lumber of any kind, as one inch thick, he receives that which is one-eighth less in thickness; and if he pays for lumber two inches thick, he receives that which is one-eighth of the whole thickness less; and the same applies to all the kinds and thickness of lumber as a rule; and if objection is raised to the measurement, the reply is always ready, "The discrepancy is the result of planing,"



and the purchaser is expected to accept the apology, as compensation for the lumber paid for but not received. If the wastage of planing is legitimately on the purchaser, he is cheated in the transaction in this; it is claimed and is a fact, that one-eighth of an inch is the necessary wastage in planing inch boards, nor does it require any more in planing lumber two inches thick; yet in the latter case a quarter of an inch is gouged out of the purchaser, and honest men—as honesty goes now-a-days—consider the transaction all right; right only because a rule, not so in fact. But if this nipping of twelve and a half per cent was all that the purchaser suffered, it would be less condemnable, but beside this he is charged the market rates of difference between the same lumber dressed and undressed, thus adding a double tax—first in the loss in thickness, and again in the direct charges for dressing. A long article might be written, illustrating the fact that in scarcely anything in the building line, particularly of American manufacture, are the sizes, measurements, weights, etc., what they purport to be.

But as we understand matters, and, as far as our personal experiences go, English law compels, in the manufacture of lumber, that, whether dressed or undressed, all thicknesses and sizes shall be up to the full standard; that when sold for one, two, or any other number of inches, it shall be so by actual measurement. And so it should be, whether of American or British manufactures.

Some years ago there was a lot of flooring shipped to San Francisco from the adjacent colony, and while it could be had, it was eagerly sought after on account of its full measurement, which compared with our Puget Sound article of seven-eighths, and sometimes scant at that, the superiority of the imported material was fully comprehended and duly appreciated by its being greatly preferred, because better in fact for all practical purposes, and better certainly as far as business morals are concerned.

THE finest glue size is made from the waste of parchment skins.

Carelessness in Sending Money.

WE cannot impress too strongly upon our Eastern and country subscribers the necessity of exercising care in sending money for subscription. During the past month, three registered letters have been sent to us in which nothing of value was found. Upon writing to the parties, in each case, it turned out that the fault lay with the parties sending the letters. Be sure and send money by postal order, or registered letter. We would sooner bear the expense of either than the annoyance caused by a miscarriage of a letter. In latter case there is always a doubt raised on either side as to the sending and receiving of money. In order to leave no room for a mistake in the future, WE WILL OURSELVES BEAR THE EXPENSE OF EITHER A POSTAL ORDER OR REGISTERED LETTER.

California Electric Engraving Company.

THIS company is now fully prepared to make engravings from photographs. Those contained in last and present issue, are the work of this Co. They are prepared especially for presses running at a high rate of speed. Can also prepare very finely executed engravings suitable for the better class of printing. This company notifies its patrons that it does not accept any cheap work. Only that of first-class character executed. All communication should be addressed to the office of this Journal, 240 Montgomery St., San Francisco.

IRON door and shutters are not the safest in case of large fires; the difficulty consists in their warping when red hot, and in that condition bursting from locks and hinges. The most approved doors are double one-inch boards, well nailed across each other diagonally, and their sides are covered with tin-plates. The hinges must reach all the way across the doors and be well fastened. The size of such a door must be two inches larger in every direction than the opening which it is intended to close. Doors constructed on such principles have been known to withstand a fire which would have destroyed the best of iron doors. Tin is preferable to galvanized iron for a covering, because it can be nailed down closely to the wood and thus dose not warp in case of fire.

Removing Spots from Gilt Frames.

GILT frames are liable to become spotted and look bad, while it is, as a rule, difficult to remove the spots. Rubbing does not answer, for the stain sticks tighter than the gilding itself, and washing is liable to loosen the gilt if put on with gum or dextrine.

The *Papier Zeitung* recommends the following method of renovating gilt frames. It consists in applying with a camel's hair pencil a gum solution to which has been added gold bronze having the color of the frame. Before mixing with the gum water the bronze must be washed with water until it runs off perfectly clear. If one application does not suffice it may be repeated until the spot entirely disappears, but of course one coat must be dry before the next is applied.

Spots treated in this way look very well at first, but it will not last, for it is not able to resist the moisture in the air unless it is specially prepared. For this purpose an ordinary bristle brush is rubbed with a piece of yellow wax until it is somewhat sticky, then it is passed very lightly over the spot several times as when dusting it. This gives it a very thin coat of wax that hardens in two or three days; in the meantime it must be protected against dust.

Ancient Roadways.

WHETHER in ancient times better roads and pavements were built than at present, or whether only the best ones remain, is uncertain, but it is certain that some of the remains of such structures found in Rome, for instance, evince engineering skill and perfection of work in a high degree. These were laid out carefully, excavated to solid ground, or in swampy places made solid by piles. Then the lowest course was of small-sized, broken stones, none less than three or four inches in diameter; over these was a course, nine inches thick, of rubble or broken stones cemented with lime, well rammed; over this a course, six inches thick, of broken bricks and pottery, also cemented with lime; upon this was laid the *pavimentum*, or pavement, composed of slabs of the hardest stone, joined and fitted together as closely as possible. This was costly—the Appian Way, about 130 miles in length, having almost exhausted the Roman treasury—but it was as enduring as nature's own work. In Peru and Central America similar remains, 1,500 to 2,000 miles long, were found by the Spaniards, which, as Prescott says, were built of heavy flags of freestone, and in some parts, at least, covered with a bituminous cement, which time has made harder than the stone itself. The roads of modern times lack most of the elements of durability which these possessed, and consequently wear out in a very few years.—*Scientific American.*

To cut the largest square from a given circular sheet, multiply the diameter by 7.071, which will give the length of one side of the square.

Our Exchanges.

WE have made arrangements with the editors of the following journals, by which we are enabled to offer quite a reduction to any one subscribing for any one of them in connection with this journal.

(The figures in parenthesis denote the price of the journals alone.)

CALIFORNIA ARCHITECT AND BUILDING NEWS.
Terms, $2.00 per annum.

With *American Architect* ($6.00), $7.00 per annum.
With *Builder and Wood Worker* ($1.00), $2.50 per annum.
With *Carpentry and Building* ($1.00), $2.50 per annum.
With *American Artisan* ($1.00), $2.50 per annum.
With *Brick, Tile, and Metal Review* ($1.00), $2.50 per annum.
With *Building* ($1.00), $2.50 per annum.
With Special Edition of *Building* ($5.00). $5.75 per annum.
With *North Western Lumberman* ($4.00), $5.00 per annum.
With *Scientific American* ($3.20), $4.50 per annum.
With *Leffels' Mechanical News* ($1.00), $2.50 per annum.
With *Decorator and Furnisher* ($4.00), $5.00 per annum.
With *American Machinist* ($2.50), $4.00 per annum.
With *The Wood Worker* ($1.00), $2.50 per annum.
With *The Builder* ($2.00), $3.50 per annum.
With *American Inventor* ($1.00), $2.50 per annum.
With *Hall's Journal of Health* ($1.00), $2 50 per annum.
With *Cincinnati Building Review* ($1.00), $2.50 per annum.

We will add to the above list from time to time, as our arrangements are perfected with the publishers. We are prepared to furnish any journal printed at the shortest possible notice.

Tin in California.

AN article in the *Mining Review*, by E. N. Robinson, C. E., states that the mine of Cajalco, in the Temiscal Range, California, has assayed 13·1 per cent. from the ore, of a purity of 0 98. This mine is believed by Cornish miners who have examined it to be a true and permanent vein, probably increasing in richness as it increases in depth.

Expansion of Portland Cement.

SOME interesting experiments on this subject have been made by Mr. Bradlee, a Boston architect. Three glass bottles were filled with cement and closely sealed. One burst in two days, one in eight days, and one in ten days, proving beyond dispute the expansive power of the cement.

THOUGH oxygen is heavier than nitrogen, and therefore ought to fall to a lower level than that gas in the atmosphere, no difference has ever been found to exist in the relative proportions of the two.

The "California Architect" is now in the Sixth Year of Publication.

Competition Designs!

ONE HUNDRED AND FIFTY DOLLARS

Cash Premiums!

FOURTH PRIZE,

Box of Drawing Instruments.

In order to promote a general desire to excel among Architects and Draughtsmen in the preparation of drawings for this Journal we have concluded to offer the following premiums for the best 4 designs of a Country Dwelling, the successful plans to be published in the CALIFORNIA ARCHITECT AND BUILDING NEWS.

1st, a Cash Prize of $60.00
2d, " " 50.00
3d, " " 40.00
4th, Box of Drawing Instruments.

Notice to Competitors.

All plans to be in the office of the CALIFORNIA ARCHITECT ON OR BEFORE the 1st of May, 1884.

All plans not accepted will be subject to the order of the owner, and will be returned upon receipt of the necessary postage.

We claim the right to reproduce in this journal all drawings of which honorable mention is made, and yet not entitled to a prize.

A *non de plume* to be used on all drawings; a letter to accompany the latter, addressed with the name used, containing also the real name and address of the contestant. This is done solely that the person's name and residence w ll not be known until the committee have made the awards

A scale of ¼ inch to the foot to be used.

Detailed estimate of cost to accompany the drawings. QUANTITY and PRICE of each material used to be given, so that allowance can be made for difference of price between the various sections of the East and this Coast.

Drawings are to show front, rear, and side elevations, with plans of the different floors.

The value of the house when finished to be ABOUT FIVE THOUSAND DOLLARS.

This competition is open to Architects in every portion of the United States.

Drawings to be made on card or bristol-board; to be line shaded; NO color but JET BLACK to be used.

All competitors will receive one year's subscription to this journal FREE, that they may see the various plans adopted

The merits of the various designs will be decided by a committee appointed by the San Francisco Chapter of Architects.

All inquiries in regard to the above will be answered by addressing a letter to the office of this journal, 240 Montgomery St., San Francisco.

WOLFE & SON, Editors and Publishers.

Staining Wood.

SIR: The art of ebonizing soft woods, and of curing the toothache, are very much alike! Every one to whom one speaks seems to cherish a pet receipt of his own, and all are declared infallible. My own unfortunate experience, however, is that whereas there are a hundred different ways of successfully staining wood black, very few things indeed exist, save patience, that are really good for the faceache!

Here are nine ordinary receipts for ebonizing, any of which the reader may find more or less useful:—

1. One gallon of vinegar, one-half pound of green copperas, one-quarter pound of China blue, two ounces of nut-galls, two pounds of extract of logwood. Boil over a slow fire, then add a pint of iron rust. Wash the wood with this.

2. First sponge the wood with a solution of chlorhydrate of aniline in water, to which a little copper chloride has been added. When dry, repeat with a solution of potassium, bichromate. Do this two or three times.

3. Boil in four quarts of water one pound of logwood, add a couple of handfuls of walnut shells (or pods). Boil again, and take out the refuse, add a pint of vinegar, and apply boiling. Afterwards dissolve one ounce of green copperas in a quart of boiling water, and apply hot.

4. Boil one-half pound of chip logwood in two quarts of water, add one ounce of pearlash, and apply hot. Now, boil one-half pound of logwood in a couple of quarts of water, as before, and add one-half ounce of verdigris, and one-half ounce of copperas, strain and put in one-half pound of rusty steel filings. With this go over the work a second time.

5. Into a quart of boiling water put one and one-half ounces of copperas and two ounces of logwood chips. Lay on hot. When dry, wet the surface again, with a solution formed of two ounces of steel filings dissolved in half a pint of vinegar.

6. Wash the wood with a concentrated aqueous solution of acetate of iron of fourteen degrees Baume. Repeat this until a deep b ack is produced.

7. Brush with a strong decoction of logwood chips several times, then give it a coat of vinegar in which rusty nails have been laid.

8. Make a solution of sulphate of iron, by dissolving two ounces of sulphate in a pint of hot water. Paint the wood repeatedly with this. When dry, apply a hot decoction of logwood and gall-nuts two or three times. When this has dried also, clean with a wet sponge before polishing.

9. Infuse gall-nuts in vinegar in which rusty nails or steel filings have soaked, and paint the wood with this.

Of course, when the work has become dry again, sandpaper down the grain, and get a smooth face, and as work to be ebonized must be quite free from holes, oil and fill in any of these with powdered drop black mixed in a filler. Then give all a coat of quick-drying varnish, and rub down with finely pulverized pumice-stone and linseed oil until a good surface is acquired.

You may get a good, wholesome varnish for ebonized work by dissolving black wax in spirits of wine.—*Harry Hems, in English Builder.*

The Making of Bits.

THERE are fourteen bit factories in the United States, eleven of which are in Connecticut. The visitor to one of these factories will first enter the forging room on the ground, where a busy and curious spectacle is presented. His sense of hearing at once becomes useless, as the clatter and clang of a multiplicity of heavy running machinery makes conversation impossible except for a man with strong lung power. From the ceiling are suspended long rows of heavy shafting filled with driving pulleys from six inches to as many feet in diameter. Instead of a floor the visitor walks on clay packed as hard and smooth as cement, and on which are carelessly thrown, in heaps, tons and tons of red hot bits. Long bars of cold steel are placed between strong shears, which cut them into appropriate lengths as easily and quickly as a lady would cut a piece of string with her scissors. Here a line of sturdy men stand beside glowing forges in which these bars of steel are placed until they are heated to a white heat, when they are immediately put under trip hammers, which, striking hundreds of blows in a minute, hammer the bars flat on one end, round in the center, and square on the other end. The bit has now started into existence, and is called in this form a "plate." It is next passed to the crimpers, who again heat it to whiteness and run it though machines which twist the flat end into a "pod," or spital of beautiful regularity. The "swedgers" seize it now, and again under the influence of the blow-pipe the steel is soon red-hot, when one blow from a powerful drop fashions the square end into a shank properly beveled for the bit brace; again it is heated and passed under another drop, which stamps on its shank a figure telling the size of the hole it will bore when finished. Once more it endures the fiery ordeal, and, glowing red, passes through the heading presses, which, with a hug and a squeeze, crush two inches of the twisted end into a mass in which you faintly discern the point spurs and cutting edges of the future bit. It is next carried into the annealing room, where, with thousands of others, it is buried beneath heaps of charcoal and thoroughly baked until the steel is well softened or annealed. Next it is pickled for several hours in vats containing a strong so ution of sulphuric acid, which eats off all the scale left by the many previous heatings in the forges.

The bit now passes into the machine room, where the rasping machine cuts out all the superfluous stock in the head, forming rude cutting edges. The milling machine cuts the point smoothly to the correct bevel, ready for the screw to be made upon it. The leveling machine smooths the bottom of the blades, the facing-back machine cuts the edges of the blades straight, the screw-cutting machine forms the threads on the point, and the sizing machine cuts the boring end to the exact diameter required.

Passing into another department, where are seen long rows of skilled mechanics seated upon high stools, each man having in front of him a heap of bits and a lot of files of various sizes and forms, known as "square," "round," "flat," "half round," "humpback," "ground off," and "feather edge," and each of these is used in turn to form and smooth the various parts and cutting surfaces of the bit. The squeaking of a hundred files of almost as many sizes and shapes fills the air with shrill notes, and sets your teeth on edge.

Pausing a moment to watch a couple of men who, seated in front of tiny forges, are heating the bits to a cherry red color and then dipping them into dishes of oil and water, you learn that they are tempering them to the proper degree of hardness for cutting.

In the "polishing room" are seen men with faces blackened by charcoal dust and emery, standing in long rows, while a sheet of fire plays from the hands of each, lighting up their blackened features and making them look like veritable demons. Each man holds in his hand a bit and presses it upon the polishing wheel, which makes many thousand revolutions in a minute, causing by its friction a great sheet of sparks to fly out in front of the operator. You behold the many different processes of finishing as the bits pass on from one workman to another down the row, until at last they look as bright as burnished silver.

In the packing room many men are sharpening the finished bits, and a few inspectors are examining them with magnifying glasses to see if they can detect any scratches that have been left by the polishers. Here, also, the bits are sorted into first-class and second quality, stamped with the manufacturer's name and trade-mark, wrapped in strips of paper, and packed in pasteboard boxes. The variety of sizes and forms run from dowel bits, hardly an inch long, up to car bits, more than two feet in length, and from the little bit cutting a hole but three-sixteenth of an inch in diameter to the great six-inch auger, which requires two strong men to turn it.—*The Wood Worker.*

IN England thin shavings of veneers of different kinds of wood are coming into use for book covers. The woods now mostly in use are our American black walnut, lime, oak, holly, etc., but all woods may be used. After being placed upon the wood the veneers can be either rubbed down with oil or French polished.

Bound volumes of 1883 now ready. Price $2.50.

Hiding Furniture.

IN the days when it was customary to make wall paper pictorially descriptive of Chinese architecture and landscape, to use bulbous furniture, to place mirrors and pictures in tame oval frames, and to balance a lace curtain hung over one-half of a window with an opaque red curtain over the other half, it was also customary to put dresses upon chairs, sofas, ottomans, and nearly everything else that would submit to such treatment. Chintz ulsters concealed the materials, and even the form of chairs; the carpet was hidden by rolls of crash, the piano legs were in pantalettes, the picture frames and chandeliers were swathed in netting, and the very curtain tassels were swathed in bags of tarlatan. Things naturally had a cheap and cloudy look in a room thus furnished, and *noli me tangere* seeemed embroidered into every sheet, and bag, and cover. There might be something under all this dusty and faded coating and carpeting that was worth seeing, but you were not in a position to swear to it, or to attest the veracity of the Pinaforic axiom, "Things are seldom what they seem." This practice of hiding furniture from view is not entirely defunct, though it is earnestly hoped that it will soon be, for one of the primary essentials of modern decoration is openness and honesty. Veneers and shams are out of date, and upholstery and hangings are made to do service, instead of being concealed beneath common-looking clothes. Better to re-bind a book when its cover is worn than never permit it to be handled. Better to have a chair upholstered anew than to keep what beauty it has from sight. In some houses furniture coverings are never taken off. When "company" is present they are retained lest the furniture be soiled, and when there is no company there is no need of displaying the treasures of the establishment. Thus reasoned the Arkansas farmer, when asked why he did not mend his leaky roof: "'Cause I don't want to go up there and work in the rain," he replied.

"But why don't you mend it in dry weather?"

"'Cause then it don't leak."

Concealment is but a form of sham. Better the simplicity of a cottage than that invisible but presumptive splendor, where the visitor is impressed with an idea that the people of the house have come into possession of costlier things than they dare to use, or that they are influenced by a petty spirit of economy that should suggest furnishing and decorating on a lower scale of cost and beauty.—*The Decorator and Furnisher.*

The Importance of the Mechanic.

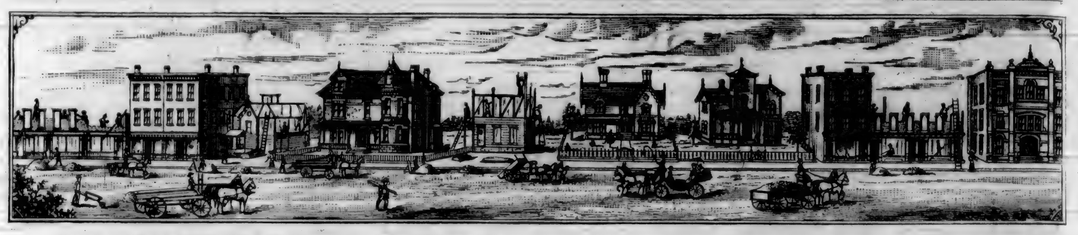
EACH ensuing day makes more prominent the fact that we have come upon the time when the mechanic is master. We have crowded professions and ill-filled trades. A chance to fill the position of sub-assistant clerk in a wholesale house is eagerly grasped at by a hundred applicants, though the wages received be scarcely more than a "chance to learn the business." Let a master workman try to obtain an apprentice at three times the salary offered the clerk, and his applicants will be poor alike in quantity and quality. A skilled workman in any trade need never want for hire; he is eagerly sought after by a hundred employers; he is independent of the condition of the market; the skill and cunning of his hand and eye are too valuable to lose, and must be paid whether the products are slowly or rapidly consumed. If business ceases, the master hand is eagerly seized by some rival house, which knows and values the product of his skill. He who would crush down the obstacles to success in our own days must have, as well as the wit to see the crevice, the strength to deal the blow. This is an age of the steam engine, and it is the engineer, not the conductor, who is master.

How Cesspools Have Been Utilized.

CESSPOOLS in a house do not fulfill the condition of immediate removal. They serve for the retention of excremental and other matters. In a porous soil it endangers the purity of the wells. The Indian cities afford numerous examples of sub-soil pollution. The Delhi ulcer was traced to the pollution of the wells from the contaminated sub-soil; and the soil in many cities and villages is loaded with nitre and salt, the chemical results of animal and vegetable refuse left to decay for many generations, from the presence of which the well-water is impure. There are many factories of saltpetre in India whose supplies are derived from this source; and during the great French wars, when England blockaded all the seaports of Europe, the first Napoleon obtained saltpetre for gunpowder from the cesspits in Paris.—*From Captain Galton's Address on House-Drainage at Chatham.*

PAINT spots may be removed from any kind of clothing by saturating with equal parts of turpentine and spirits of ammonia.

We thank those of our subscribers who have so promptly forwarded their subscriptions. But there are many who have not as yet sent us the amount necessary to continue their names on our books. By promptly forwarding us $2.00 you will greatly aid us in our desires to make still further improvements in this Journal.



BUILDING INTELLIGENCE.

SAN FRANCISCO.

Battery, near Bush. Additions to brick building.
O.—
A.—Wolfe & Son.
C.—T. H. Day.
$11,000.

Clay x Van Ness and Franklin. Two-story frame.
O.—Max Isaacl.
A.—Wolfe & Son.
C.— — Wickersham.
$7,000.

O'Farrell, near Stockton. Five-story brick and stone.
O.—M. De Young.
A.—W. Patten.
C.—McGowan & Butler. brick work.
$160,000.

Tyler, corner Polk. Remodeling.
O.—Central Presbyterian Church.
A.—J. Marquis.
C.—W. B. Ellis.
$15,000.

Larkin, corner McAllister. Finishing interior of City Hall.
A.—Curtis & Bennett.
C.—J. K. Delmas.
$12,700.

Fillmore, corner Pacific. Two-story frame.
O.—J. P. Treanor.
A.—Percy & Hamilton.
C.—Gray & Stover.
$8,000.

Stevenson, near Third. Three story and basement brick.
O.—Mrs. Nuttall.
A.—A. Pissis.
C.—J. Geary.
$7,700.

Buchanan, cor. McAllister. Two two-story frames.
O.—F. Junker.
A.—W. H. Bayless.
C.—J. Owens.
$4,550.

Devisadero, near Geary. Four two-story frames.
O.—C. Ahlborn.
A.—H. Geilfuss.
C.—Chrisman & Neal.
$10,000.

Market, near Third. Repairs.
O.—Blythe estate.
C.—P. M. Quackenbush.
$1,000.

Lapidge, near Eighteenth. Two-story frame.
O.—T. Redington.
C.—C. Kinsman.
$1,900.

Lapidge, near Eighteenth. One-story and basement frame.
O.—J. Nichol.
Day's work.
$2,000.

Valencia, nr. Ridley. Five one-story frames.
O.—R. Tobin.
C.—F. Buckley.
$2,500.

Valencia, near Sixteenth. Additions.
O.—Eastman & Co.
Day's work.
$1,500.

Seventeenth, nr. Church. Two-story frame.
O.—B. Burns.
C.—D. Spangler.
$3,600.

Diamond, nr. Seventeenth. Two-story frame.
O.—M. Martin.
Day's work.
$2,000.

Sanches, nr. Market. One-story frame.
O.— —.
C.—J. W. Smith.
$1,000.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in DEWEY & Co's. SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

For week ending January 29, 1884.

292,531.—Fire escape ladder—A. J. Bartlett, Elk Flat, Ogn.

292,624.—Pilot or Guard for Cable R. R. cars—W. U. Bohm, S. F.

292,543.—Quartz Crusher—Dandurand & Lafrance, Virginia, Nev.

292,629.—Can Holder and Funnel—W. M. Doty, Biggs Station, Cal.

292,740.—Spring Vehicle—P. Englehart, Modesto, Cal.

292,552.—Ornamentation of Frame Mouldings—P. E. Francke, S. F.

292,480.—Two-wheeled Vehicle—H. P. Garland, San Quentin, Cal.

292,555.—Excavator and Leveler—B. M. Hague, Wild Flower, Cal.

292,556.—Bed Lounge—A. Hansen, S. F.

10,440.—Indicator Padlock—A. Jackson, S. F. (reissued).

292,574.—Hinge—W. Patterson, S. F.

10,443.—Can Opener—Frank Sharp, Los Angeles, (reissued).

292,666.—Lifting Jack—B. F. Mansfield, Centerville, Ogn.

PROPOSALS FOR THE CONSTRUCTION
OF THE
New Odd Fellows' Hall.

SEALED BIDS WILL BE RECEIVED AT THE OFFICE OF The Odd Fellows' Hall Association of San Francisco, Room No. 1, Odd Fellows' Hall, No 325 Montgomery street, San Francisco, up to and until 12 o'clock M., of

FEBRUARY TWENTY-SEVENTH, 1884,

For the erection of the New Odd Fellows' Hall, on the lot on the southwest corner of Market and Seventh streets. Bids to be received for the separate trades, as follows:

No. 1—Brickwork.
No. 2—Carpenters' and Joiners' Work.
No. 3—Granite and Freestone Work.
No. 4—Cast Iron Work.
No. 5—Wrought Iron Work.
No. 6—Tin and Slaters Work.
No. 7—Plumbers' and Gasfitters' Work.
No. 8—Plasterers' Work.
No. 9—Painters' and Glaziers' Work.

The plans and Specifications of said building can be seen at the office of Messrs. Wright & Saunders, No. 418 California street, and will there be open to public inspection after the date hereof.

The successful bidders will be required to furnish bonds, satisfactory to the Board of Directors, for the faithful completion of the work in accordance with the plans and specifications. The Board of Directors reserve the right to reject any or all bids.

C. T. FIDWELL, Secretary
of the above-named Association.

San Francisco, January 26, 1884.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.
Back Cover, outside, each insertion, $2.00 per square.
Page preceding reading matter, $1.75 per square.
Page following reading matter, $1.50 per square,
Inside Pages, each insertion, $1.00 per square.
Full Page, inside, one insertion, $40.00.
Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

OUR COMPETITION PLANS.

Notice to Competitors.

All competitors are notified to have their plans at the office of this journal on or before the first day of May, 1884.

The meeting of the San Francisco Chapter of Architects will be held on Friday evening, May 2d, and it is necessary that all plans should be laid before the committee at that meeting.

Parties living outside this city will please take notice that plans should be sent so as to reach this office not later than above date.

Our Building Interests.

REVIEW OF THE FIRST QUARTER OF 1884.

THE first quarter of this year, ending March 10th, having now closed, a review of the *facts* of the past, and the *probabilities* of the future may be intelligently indulged in. With the close of 1883, and the advent of its successor, the feeling and sentiment was universally in favor of great things in the general prosperity of the State, and particularly in the building business for 1884. But as January advanced with scarcely a shower of rain to keep up and strengthen the hopes inspired by and founded upon the prevailing solid financial and business conditions generally, the shadow of doubt gathered around many, and—"the country is ruined for want of rains," was heard almost everywhere. But a kind Providence, in due and acceptable time, washed away all the thousand evils that had seemingly been gathering, and by copious showers, during the latter part of January and in February, watered the face of the earth throughout our fair State so generally and bountifully that, with the advent of the second month of the quarter, the spirit of rejoicing returned, and all hearts were made glad; and March, with its transcendently lovely weather—unsurpassed by Italian skies and breezes, finds the people of the entire Pacific Coast in a most happy and hopeful frame of mind, not one seeming to fear but that a season of unprecedented prosperity is before us, and that none who may live in health until the year closes will have reason to complain that the good angel that distributes the bounties of successes has passed any by, without bestowing the rewards due to each, according to his diligence in business, and prudent use and manipulation of the opportunities that will have been within his reach. But what of the three months past? They have been excellently prolific in building activities—season considered—as far as actual operations are concerned. But there is more than this to the credit of the first quarter. It has been the seeding time in fields architectural, in which the germ of many of the activities of succeeding months have been planted. At present the tide of business is at its ebb, with still smooth water. Soon the flow will be inward and upward, and ere long the rushing of the tide will call into active service every man and lad within the boundaries of our State, willing to labor, and that, too, at remunerative rates of wages. We are confident of more; there is not sufficient labor force in California to supply the demand that is sure to come, and unless an increase of competent labor shall incline or be induced to come this way, there will be a repetition of what has several times occurred within the past three years—that of signs nailed up on buildings under way, "Carpenters wanted," "Brick layers wanted," etc., and the further resort, under pressures, of bosses offering four bits or one dollar per day advance to draw help from other parties. The future! Just what we have above outlined. There are at the present moment plans matured and preparing for brick structures, which alone will consume all usual supplies for bricks, lumber, and other materials, and give employment to every mechanic willing to work; besides which there are to be hundreds of dwelling houses and private residences erected, all of which combined are bound to lick up all the material and labor that can be introduced into San Francisco.

A NOTABLE SHOWING.

Contrary to the reports given in some of our local journals, the present quarter shows a remarkable degree of activity. In spite of the rainy weather experienced, it will be noticed that but two months in the year 1883 exceeded the present month in the number of new buildings and improvements started.

SUMMARY.

January, 1884,	30 frame buildings, value,		$176,600

198 Buildings, of Value of $1,065,030.

This is the most remarkable showing ever given for a similar period in the history of the city.

For the same period in 1883, we find

153 BUILDINGS OF VALUE OF $904,489.

When it is taken into consideration that the weather has been such since the beginning

of the year that hardly one-half of the time could be utilized for building operations, the above synopsis is very favorable, and is a criterion to judge of the future.

THE BRICK DEMAND.

From present indications, the coming season will be one of unusual activity in the erection of brick buildings. There is a superabundance of capital in search of profitable investments, and since the rush for railroading, mining, and stock operations has, in a great measure subsided, this by no means new field, that of building, affords the greatest attraction, holding out, as it does, the assurance of a fair return on the investment, and almost absolute security. The substantial appearance and increased security against fire, of brick compared to wooden structures, will tend to increase the demand for brick and other clay products that enter into their construction. Terra cotta is coming into a more extended use, and as it is claimed for it, absolutely fire proof and indestructible by time and weather, we apprehend it will not be long before all the ornaments and trimmings on the outside of brick buildings will be made of that material.

Our brick manufacturers are even at the present time very busy, and many have their whole year's product already engaged. Pressed bricks from San Jose are now coming into prominence. We would suggest to the manufacturer, that it should be his endeavor to manufacture his brick as nearly as possible of the size of the rough brick generally used in buildings, on account of keeping the courses as nearly even as possible, where pressed brick are used on the face of a building and rough brick for backing.

BUILDING ACTIVITY GENERAL.

From every portion of the State we hear of increased activity in building circles. The immense amount of money necessary to repair damages to the bridges, railroads, etc., in the southern part of our State, will cause great activities in the localities affected.

In this city, a review of last year's summary will show that an unusual large number of small buildings was erected by the laboring class of our population, and with the bright prospects now appearing, we think the number will be largely augmented this year.

AN imitation of and substitute for mahogany, useful in fine manufactures, is due to French ingenuity. The first operation is to plane the surface of any species of close-grained wood until it is perfectly smooth, and it is then rubbed with diluted nitrous acid, which prepares it for the materials subsequently to be applied. These consist of one and a half ounces of dragon's blood, dissolved in a pint of spirits of wine, and one-third of that quantity of carbonate of soda, mixed together and filtered, the liquid in this state being rubbed, or rather laid upon the wood with a soft brush. This process is repeated with very little alteration, and, in a short interval, the wood possesses all the appearance of mahogany.

San Francisco Chapter American Institute of Architects.

THE regular monthly meeting was held in the rooms of the Art Association, on Friday evening, March 7th. President John Wright in the Chair.

The minutes of the preceding meeting were corrected so that the report of the committee appointed to wait upon the Pioneers should read as follows:—

The Pioneers were willing, through their committee, to adopt the suggestions advanced by the Architects, with the exception of the one relating to the value of the premiums. This they had no right to alter.

A committee—Messrs. Wilson, Gray, and Kean—from the Master Plumbers' Association, being in waiting, they were accorded a hearing. The Chairman of the Committee, Wilson, asked the Chapter to consider the following propositions: That all members of the Chapter be requested to include all sewer work—iron-stone pipe included—in the plumbers' specifications. It was claimed that defective sewer work very frequently occurs in sewerages, producing offensive results, for which plumbers receive censurse; and that in some cases it has become necessary for plumbers to tear out the whole of the work done to obtain proper drainage, all of which, it was claimed, might be avoided, if the whole of the pipe work of buildings, sewers included, was placed in the hands of the plumber, who would then become the responsible party for the sanitary conditions of buildings. The committee also urged that the segregation of the plumbing work, and its letting by separate contract be made the rule.

The committee then withdrew, and the regular order of business was proceeded with.

The committee appointed to secure a seal for the Chapter reported that it would be done in a few days. Extra time had been taken in order to present a seal that would have artistic merit in its design.

Committee in regard to competition, and the rules governing the same, requested further time.

L. Stone was elected a student member. Propositions received from C. I. Havens as a fellow, and L. M. Turten as a student member. Referred to Messrs. Curlett, Pissis, and Henriksen.

A motion was made that a committee be appointed to prepare a blank indenture and articles of agreement between architects and pupils, and their parents or guardians, so that all architects could use the same form in regard to articled students. The said form to contain specifically the rates paid to the students during their apprenticeship.

The motion was unanimously adopted, and Messrs. Curlett, Sanders, and Pissis appointed as such committee.

Resignation of Joseph Gosling received and accepted.

The subject introduced by the Master Plumbers' committee was then taken up, and received a thorough and general discussion from all the members present.

It was not deemed advisable that plumbers should undertake to do work properly belonging to the mason. Cement or iron-stone pipes had to be laid by one familiar with the use of the trowel. In many cases a brick sewer was laid from the main to the edge of the sidewalk, and, in this case, it would be taking from one trade in order to swell the amount of contract of another.

The report of the Plumbers' committee was also deemed a reflection upon the architect. The latter always required a sewer to be left open until inspected, and the plumbers, by claiming that sewer pipes were not graded to correspond with their work, deflection of pipes being such that joints were sometimes broken, ends of the pipes not filled properly with cement, thereby causing in a short time offensive smells to permeate through the ground, etc, etc., placed themselves in a position as a superior in judgment to those whose duty it was to superintend every portion of the building.

It was the sense of the Chapter that the sewer work rightfully belonged TO, and should be done BY the mason.

A motion was made and unanimously carried, that hereafter all trade organizations or associations desiring to make any complaints or state any grievances, must do so in writing, the same to be handed to the Secretary before the regular meeting of the Chapter.

A short discussion then ensued upon some of the provisions of the fire ordinance. No action taken in regard thereto.

Motion made and carried that hereafter all members who are in arrears one year's dues, after receiving notice from the Secretary to pay the same, and failing to do so, shall have their names stricken from the roll until all such arrearages are paid.

Adjourned.

The office of the Secretary of the Chapter is located at 240 Montgomery St., Room 11, San Francisco.

Master Masons.

SINCE their organization upon the basis of being entitled to *original contracts with owners* in all sums exceeding $300, they have managed their interests intelligently, standing by the rule adopted, and the rule working no hardship. In our own case we have managed in this way: When the amount of mason's work has exceeded the limit in the erection of frame buildings, where the mason work has been scarcely sufficient to justify segregation, viz., to have the carpenter draw an order upon the owner for the sum of mason's estimate, say $325 or any other amount, made payable out of the respective payments as written in the carpenter's contracts, and the owner upon this order entering into a separate agreement to pay the mason, all of which can be accomplished with but little tax upon the time of any *good natured* architect or any one else.

We certainly favor the position assumed by the master masons, for the reason that if the combining of all branches in one contract is an advantage to *one man or firm*, the contractor, that advantage is secured at some sacrifice to sub-contractors' interests, who are under such circumstances placed at the greater disadvantage of more unequal competition and sometimes questionable manipulators, in the handling of bids, while bidding in the usual way, as first contractors, offers greater security as to fairness and equality of competition, as it but seldom happens that either owners or architects seek or permit bids from, or are willing to let work to doubtful parties, and it is a matter of no little interest and importance to architects to have all work fall into the hands of competent men.

Besides all these considerations, the effect of raising the mason's trade from sub to original contractors, will be decidedly good and manifest upon the masons as a class, as it will remove every feeling of subserviency and awaken and inspire the better and more manly feelings. The fact needs no argument in support; men as a rule are influenced in every way by the circumstances surrounding them. However great and good, however intelligent and masterly a man may be, these qualifications and attainments may be improved and enlarged by surrounding conditions and influences. And so in mechanical life. All that tend to lift up and develop the better qualities are the points to be desired.

Shyster Architects.

WE know of no more appropriate term to apply to that class of individuals who infest, and by their dishonorable and unprincipled acts disgrace the Architectural Profession, than that of shyster as defined by Webster's unabridged.

A CASE IN POINT.—A firm of architects in this city was introduced to an owner who contemplated the erection of a building to cost about or rising $4,000. Satisfactory arrangements were at once made, and the order given to prepare the preliminary sketches, the purchase of one of two lots in view depending upon suitableness of plans to lot. Consequently accurate plans in full were prepared, and the lot purchased accordingly. After the purchase, information of the fact was communicated to a firm of two, who reached this terrestrial state of existence through the same parental channels, by a member of the real estate firm selling the lot. As in all such cases the soliciting member at his earliest convenience hastened in search of the purchaser, and by his usual misstatements of "we can build houses cheaper than anybody else, especially architect number one," and his misrepresentations of others, endeavored to secure an engagement, after being told by the purchaser that architect one had been engaged. Several other turns were afterwards made to humbug the owner of the lot, and take the job away from the parties whose plans had been accepted and approved before the **MIS-delineator of Eastlake** knew that the owners in question lived. But to "make a long story short," we give the final, the more disgraceful and morally and professionally dishonest part of the transaction.

The plans adopted were estimated upon, and, the result exceeding the limits, the specifications were modified, and the price reduced by a second competition of eight competent contractors to $4,434, which proved acceptable to the owners; but a delay in commencing construction occurred by reason of title searching and money matters. It seems to have occurred to the marauders upon other people's rights, that the opportunity was open for another "dirty piece of work," and so the owner was again sought, and the *lie* repeated that "we can build you a house cheaper than number one," while in fact their knowledge of the building science and of proper construction, if no better was possessed by, would reflect no credit upon the intelligence and mechanical smartness of any apprentice boy of three years' service at building trade. And further said he to the owner—the words may differ but the sense is *exactly* the same—"We are going into the business and need the influence of your building. Mr. ——, number one, is about the oldest architect in the city and don't need your work. If, therefore, you will dismiss number one and pay them $90.00, we will build your house at a cost of $3,800, and charge you but 2½ per cent., out of which we will return or pay the $90.00." The quick discernment of the owner in a moment detected the concealed roguery that was intended, and repudiated the proposition. That rascality was intended is beyond question, for with $3,800 as the cost, 2½ per cent. would return in percentage just $95.00, from which deduct the $90.00 to be paid to number one, and the grand balance of $5.00 for plans, the specifications, superintendence, and commissions to real estate agent would remain. It is unnecessary to add more, as the unmentioned facts are so clearly transparent that any intelligent owner must readily comprehend them. That there are possibilities of improvement in the practice as architects, is altogether likely, but we question whether the science will ever reach a level at which $5.00 will be considered a fair compensation for architectural services and outside commissions on buildings costing $3,800, with the slightest tincture of professional integrity and honesty attached. What we have said is from personal knowledge, being one of the interested parties.

Bancroft's Histories.

ELEVEN volumes of this work have been completed. Interest grows with each succeeding issue, as the times and incidents approach within the memory of many now living. No student can afford to be without this set of works. It will comprise thirty-nine volumes. Prices can be obtained at the office of this journal.

Separate Contracts.

THE plumbers appeared by committee before the Chapter of Architects at its last session, asking among other things that the segregation of the plumbing work of buildings be made the rule. This request should have been qualified by saying that several of the architects in San Francisco have for years pursued just that course, and credit should have been given to those who have for so long a time practised the segregation plan.

As interest dictates, arguments run pro and con among original and sub contractors; so that architects and owners must judge and act for themselves. It would involve great trouble and distraction if *all* the branches were to set up the same claim, and refuse to submit to sub contracts.

The principal contract should carry all except the more prominent branches, if not all. The plumbing and painting may consistently be segregated in moderate cost houses, and in better residences the plastering also may be separated. In brick buildings three separate contracts are feasible, to wit, mason, carrying the grading, sewerages, etc., the iron-worker, and carpenter, the latter comprehending all not included in the mason's and iron-worker's branches. The plastering and cement work also is frequently of such magnitude as to justify segregation. But in all such matters if each architect and owner will act just as he sees fit, and let matters be arranged as they may, there will always be found those who will be willing to accept sub contracts, situations and conditions.

Obscuring Glass.

THERE are many ways of accomplishing this, some of the plans making the glass permanently frosted, others only temporarily so. For permanence, take a flat piece of marble, dip it into glass-cutters' sharp sand, moistened with water; rub over the glass, dipping frequently in sand and water. If the frosting is required very fine, finish off with emery and water. As a temporary frosting for windows, mix together a strong, *hot* solution of Epsom salts and a clear solution of gum arabic; apply warm. Or use a strong solution of sulphate of soda, warm; and when cool, wash with gum water. Or dab the glass with a lump of glaziers' putty, carefully and uniformly, until the surface is equally covered. This is an excellent imitation of ground glass, and is not disturbed by rain or damp.

Sensible Building.

THE Egyptians of to-day commence the building of a house by tracing an outline plan on the ground with plaster, and a very sensible way it is, too. No danger that the front steps will over-reach on the sidewalk, nor the rain from the roof slop over upon the neighbors, because the plan is too big for the lot.

Science of Carpentry, $5.00.

New York Notes.

BY A. CURTIS BOND.

I CANNOT refrain opening my letter this month with a reference to the intolerable weather we have had to endure for the past four weeks. It has indeed been unprecedented in New York experience, and singularly enough, instead of wasting its strength as the weeks have gone past, the storm has positively seemed to increase in violence and wickedness, until to-night its fury appears to be fully developed into a tornado of the most cyclonic proportions and of sufficient force to blow down a row of three unfinished houses in the upper part of the city. Whether the comparative ease with which these buildings were destroyed, or rather thrown to the ground, reflects upon the character of modern building, I will not undertake to say, but it is merely a repetition of what has occurred heretofore in some of our principal streets. Not long ago four dwellings, quite pretentious in their size and appearance, and completed above the third floor, succumbed to a "Nor'easter," and were scattered pretty well over the best part of a block.

Naturally, during this stormy spell, outside work upon all sorts of edifices has been at a standstill, and no practical advance has been made in any of the many buildings which are about beginning, or are just beyond the beginning stages.

Since I last referred to our city architecture there has been very much going on in the way of building, and some of the most prominent houses have been put up. Mr. Charles L. Tiffany, the head of the well-known jewelry firm, has a magnificent and most extensive affair at Seventy-second Street and Madison Avenue. It is evidently in the Venetian style, being perfectly plain and extremely massive. A dark slate-colored stone forms the lower part of the building, and extends up to the third story, beyond which brick is used. In the place of a front stoop, an arched passage or gateway admits one to an open interior court, from which rise stairs to the different flats. The object of the enormous structure is to contain or provide accommodations for the entire Tiffany family, and it looks large enough to do it.

H. G. Marquand, who is known in New York as a director in almost every one of the large corporations, railroads, etc., that center at this place, has just completed a marvelous structure of stone at Sixty-eighth Street and Madison Avenue, and, it is said, is having it decorated at an expenditure of over $100,000.

Mr. Villard had not quite finished his houses when his failure occurred. They are gorgeous buildings, three in number, occupying an entire block, and combining all sorts of accessories, such as a swimming bath, concert room, and a variety of other unusual features.

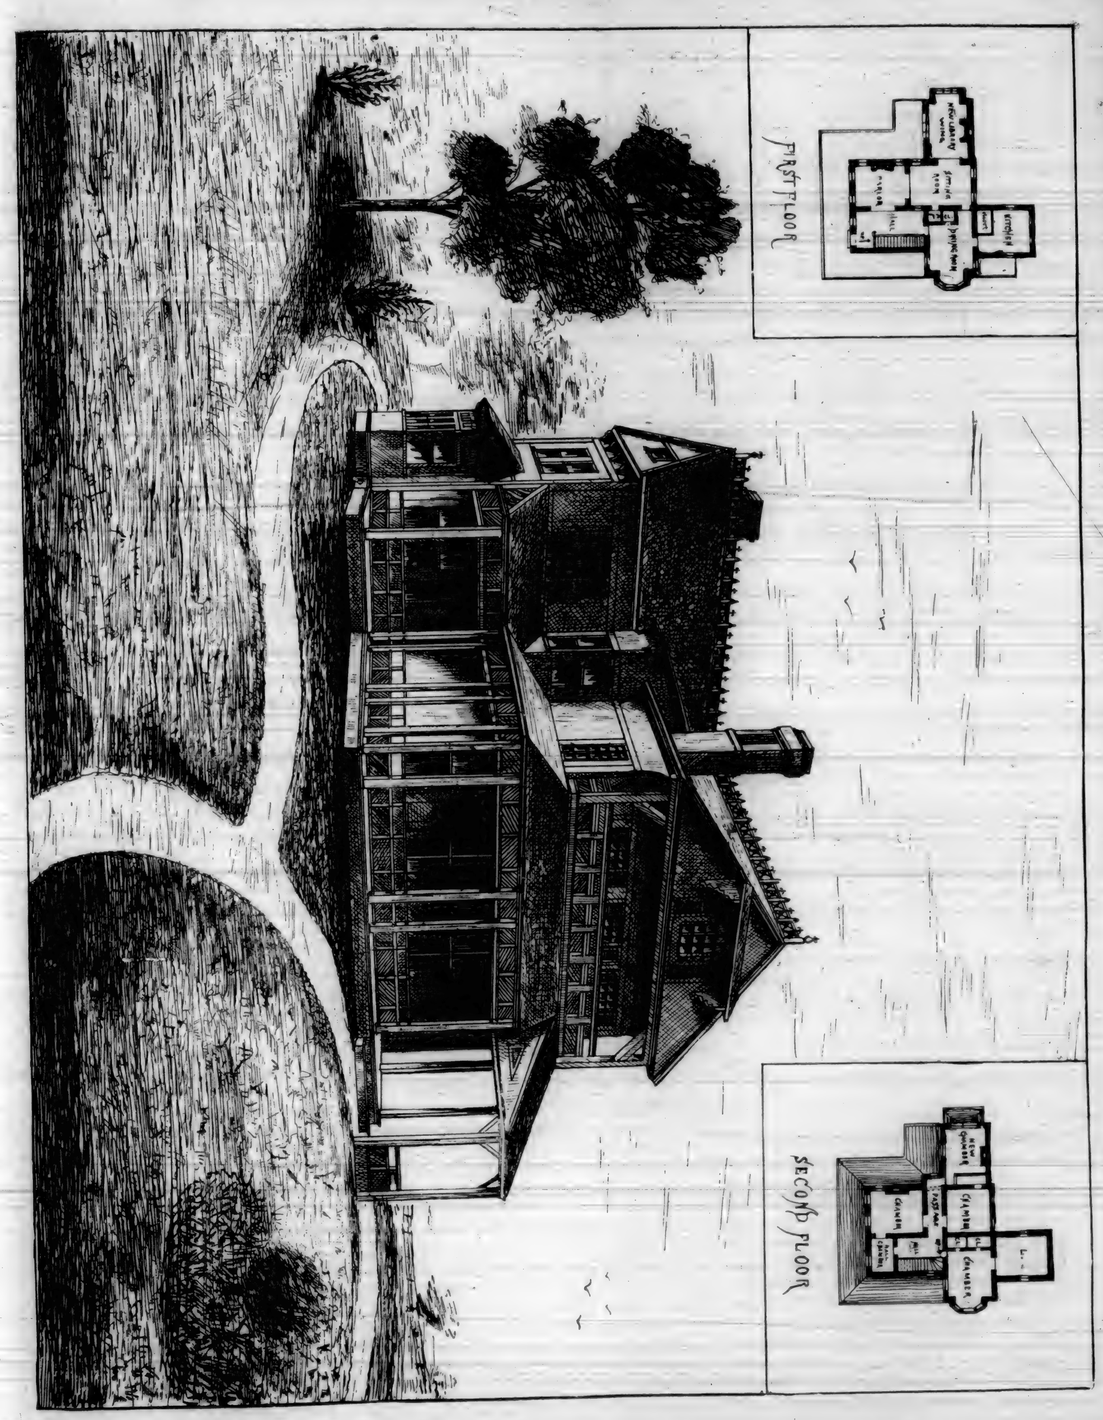
There is a house built some years ago, and still a sight among our local curiosities, known as the Ward House, standing on Forty-seventh Street, a few feet from Fifth Avenue, the fashionable quarter of the metropolis. It is a low and long building somewhat after the principle of the English country halls or palaces, has a very extensive park around it (ground worth $10,000 to $30,000 per lot of 25x100 feet), with trees and fountains, and within the walls of the building itself is a theater, a swimming bath, a raquet court, and a multitude of other "queer" things.

There has been much attention given the subject of the protection of buildings from lightning. The approach of the season when the danger from this form of accident is the most threatening, has no doubt brought the matter more directly to the notice of our architects, and, singularly enough, a difference of opinion has arisen upon the very last point, it would seem to the non-scientific, that could possibly be raised, and that is the direction in which lightning strikes, whether downward from the clouds, or, having descended to the earth, it strikes the building from below and travels upward again. The downward course has the majority of adherents certainly, though those advocating the upward tendency are numerous and persistent, and fortify their position with such reasonable argument as to be, in a measure, conclusive. The result of the discussion thus far has been to establish the necessity of four qualities in the rod, (1) size, (2) continuity, (3) earth contact, (4) pointed summit. The first requires that sufficient capacity should be assured for the accommodation of the electric fluid; the second, that continuity should be absolutely perfect, joints avoided as far as possible, and when unavoidable that they should be well soldered; the third and probably most important is that the rod should terminate in a mass of metal and be implanted in earth permanently damp; and fourth, that the summit of the rod should be a point, short and thick; too sharp a point is readily fused, while one that is too blunt has not sufficient conductive power.

I don't know but that I have dwelt rather more upon this subject of lightning than may be thought necessary, although it is one so fruitful of mischief and full of destructive elements as to make it of interest, I should think, to every architect.

A rather singular case with an unusual (for this country, at any rate) termination is reported from Belgium, where the architects of a large building brought a suit in copyright against the proprietors of a local paper for publishing without their permission an engraving of the building designed and built by the architects in question. The paper claimed that inasmuch as the building was completed, stood upon a public street, and was freely open to the public for inspection, it became, in a question, public property, and therefore they were entitled, or at least excusable, in reproducing it. The judge thought otherwise, however, and compelled the paper to print an apology and pay the costs of the action. I would not undertake to question the justice of this decision, for I do not feel qualified to do so, but I fear if the law prevailed here, it might be taken advantage of to such an extent as to put illustrations of this character almost under a ban.

A very decided movement has been made to improve the condition of the tenement houses of this city. Attention was publicly called to their absolute unfitness as dwellings, by Pro. Felix Adler, the young liberal preacher, who went out from Judaism and established an independent and entirely unsectarian organization for rational preaching and good works among the poorer classes. His weekly discourses are attended by many of the prominent and intellectual people among us, Jew and Gentile alike, and among his other excellent endeavors, this latest one of reform in tenement existence is certainly worthy of all the support it is receiving. He has finally persuaded our lethargic city government to take hold of the matter, and it begins to look as though the miserable rookeries and sinks that have been a disgrace ever since this island was called New Amsterdam are about to be cleaned out and renovated. A law was passed not long ago, making it necessary that the plans of all proposed buildings be submitted to the Board of Health, and that Board would determine as to the sanitary prospects of the building, its air, ventilation, cleanliness, its strength, safety, etc. So the more recent buildings combine most of the modern improvements, and objectionable features are not permitted to intrude. The difficulty is with those tenements which have been made from previously private dwellings or warehouses. Lacking the conveniences for the accommodation of masses, they have degenerated into pestilential spots, from which originate seven-eighths of the violence and crime to which we are subjected. In contending with this, Professor Adler has had, and the Board of Health will have, not only the opposition of the owners of the property who naturally are opposed to any compulsory expenditure of capital, but actually the opposition of the tenants who have, as a rule, become so accustomed to the degradation and filth of their surroundings as to object to any change for their seeming improvement. The depth to which the worst element of New York's population has sunken, is almost beyond belief to one who has had no opportunity of visiting their living-places. Four families living in one room is by no means an uncommon incident, and it can be readily understood that the atmosphere in these buildings is almost overpowering. Public baths have been established, hoping to encourage these people in cleanliness, but the effort has been fruitless; the baths are patronized, but not by this class; shop girls and the great family of working men and boys throng the baths, together with newsboys and bootblacks. The criminal mass is not found there, however; the stagnant, dirty, those who waste their time in these miserable tenements, smoking, gambling, murdering, never take the trouble to remove their clothes; certainly, they would scarcely attempt to bathe. So it is necessary, if any-



COTTAGE DESIGN.—NEW YORK ARCHITECTURE.

FRONT ELEVATION OF A COUNTRY DWELLING, COSTING ABOUT $2,500.

thing is to be done to better this condition of affairs, to do it forcibly, and this is now being attempted. The disposition to visit these low places has become very marked, and parties of ladies and gentlemen are made up to take a tour of the "dives" and under-ground resorts of the lower wards. The recent expeditions of the Prince of Wales through the slums of London have served to popularize this sort of entertainment in England, although the residents of the localities in question are said to resent the intrusion with considerable warmth, increased, no doubt, by the fact that the ladies of the parties wear heavy cloaks to conceal their fine dresses and jewelry. This divertisement is now known as "slumming."

. . . . . .

The cottage I show this month is designed for an inexpensive affair, though combining many excellent features. The exterior arrangement of piazzas and shade is well arranged for summer use, the small balcony from the second story being adapted to pleasant afternoons and protection from the sun. In studying the plans, shown at the upper corners of the plate, it will be seen that each room has one or more windows, insuring thus perfect light and ventilation. The plans show the wing that may or may not be attached to the house proper. The rooms in this wing have been designated as "New Chamber," "New Library."

Estimating Quantities of Paint.

IN a former paper we attempted to offer some suggestions on the measurement of surfaces; our attention may now properly be given to the consideration of some of the causes of variation in estimating quantities, some of which seem to be entirely lost sight of, and others are only partially understood.

Nature of Surfaces.—On all wooden buildings there are places more or less numerous which cannot be reached with a brush, so that the paint applied can be spread with the same care than it can on the more exposed portions. The edges of the siding, the joints and cracks between boards, the almost inaccessible portions of brackets, scrolls, latticework, and other ornamental parts, absorb a much greater quantity of paint than an indifferent or inexperienced person could easily guess, and unless some allowance is made for them, there is quite likely to be disappointment. Old buildings which have been allowed to stand many years without painting usually have a rough and peculiarly absorbent surface, caused by the swelling, shrinking, and decay common to wood unprotected by paint. This will apply even more forcibly to buildings which have never been painted. On new buildings, also, there is a great difference between the quality and finish of lumber, which the painter would do well to note—some being extremely shaky and porous, and perhaps poorly planed, while others present an entirely satisfactory surface. Brick buildings present some quite noticeable variations, both in the material of which they are made and in the quality of the mason work. Some brick have a hard, smooth surface; others are soft and porous. The hard brick are much more durable, and of course require less paint to cover them.

The same general hints will apply to interior surfaces. Allowance must be made for the finish of walls which are to be painted. The rough walls now preferred by many on account of their durability, require a great deal of paint and sometimes a coat of glue size between the first and second coats of paint, to give them anything like a fine appearance. On interior woodwork, elaborate architectural features, in the shape of mouldings, panels, cornice, continuously projecting and receding, with very little really flat surface, much more time and material are required to suitably finish them than plainer work.

Mismeasurement.—Without a proper basis for calculating quantity, it is impossible to be accurate. If some portion of a building has been carelessly omitted from an estimate, if a blunder has been committed, if proper allowance has not been made for trimmings and surfaces, it will be impossible to secure an accurate estimate. It will be well to add ten per cent. to the quantity determined upon on the basis of measurement to cover contingencies. It is better to have a little paint left after a job is done than to run short.

Climate.—The state of the weather affects the covering qualities of paint, on account of the susceptibility of oil to cold and heat; hence more paint will be required to cover a given surface in cold than in warm weather.

Manual Skill.—Besides the difference in surfaces and conditions, there is quite as marked a difference in the skill of workmen. A strong, active man who handles the brush in a masterly way, making telling strokes without waste in laps, will make paint go further and do better work than a weak or an indolent man or boy. The idea that men who are equally proficient at the dinner table are in all other places, is not a correct one to be guided by in selecting workmen. Skill is nowhere more valuable, and in few places more economical, than among painters.

Paint.—The quality of paint determines in a measure its covering power. That which is made of pure linseed oil, properly mixed, and of the right consistency, possesses the greatest covering power as well as the best preservative qualities, and it is to paint of this kind, as distinguished from cheap alkali paints, that our remarks are designed to apply. If these hints are duly considered in estimating quantities, we think that the apparent inconsistencies of the claims made for the quality and covering capacity of good paint will not seriously puzzle unprejudiced minds. Every man ought to know that it will take more paint to cover a rough surface than a smooth one, as well as that it will take more strength to draw a heavy load up a hill than on level ground. —*The Painter.*

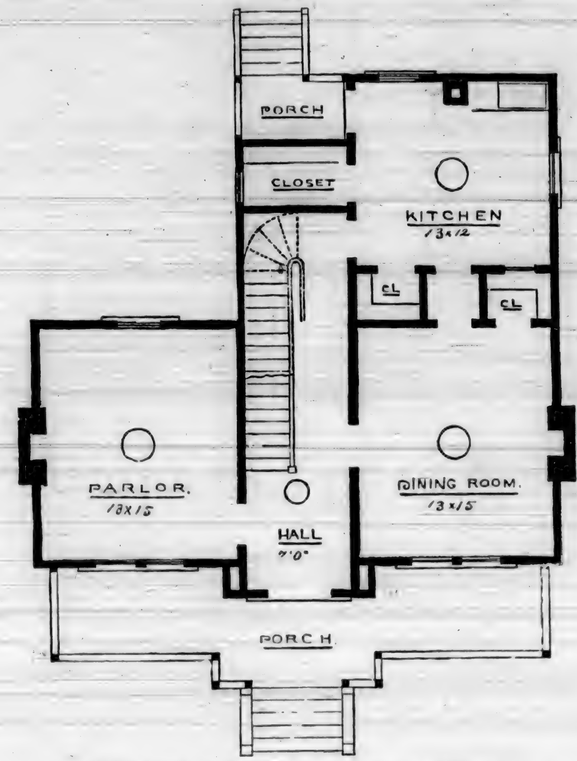
Painters' Measurements.

WE have taken considerable pains to look into the matter of measurement of surfaces to be painted. In addition to our own knowledge, we have inquired of practical painters accustomed to estimate on work, concerning their methods of calculation, and we have failed to find any uniform scale or rule by which to measure surfaces. Nearly all master painters have a basis of calculation, but the accuracy of their estimates depends so much upon personal judgment as to the nature and extent of variations, that their methods would be useless to persons of less accurate judgment. Besides, the methods vary according to the nature of the work and the training of the painter. No two would measure in the same way, perhaps; yet they might reach precisely the same results. Although it is true that very much depends upon the painter's judgment, we shall try to give a few hints which will be found in some cases entirely trustworthy, and in all helpful.

One way of measuring is to get the number of square feet in the sides and ends of a building as if they were flat surfaces, give a rough guess as to the dimensions of trimmings, etc., and let it go at that. This plan may work well for a good guesser, but for general use it does not prove very satisfactory. Another way on wooden buildings is to measure the length and exposed surface of one strip of siding, count the siding, and multiply the dimensions of one by the whole number on the side or end of a building, and the product will be surface measure; trimmings, etc., are measured separately. This is a better way, but its accuracy depends upon a pretty thorough acquaintance with compound numbers, as dimensions must be reduced to inches, then back to feet or yards, according to the basis of calculation.

Common siding are put on by the carpenter with one board overlapping another, and the lapping edge of the board is raised from perpendicular, so that it presents a diagonal instead of a flat surface, and there is also the exposed edge of the board, about half an inch, which should be included in the estimate. Suppose, now, that the exposed portion of a board of siding is four inches, the usual width, and the edge half an inch, it will give the side of a building just twelve and one-half per cent. more surface than it would possess if it were perfectly flat. Hence twelve and one-half per cent. added to the dimensions obtained by multiplying height and length together, will give the actual surface measure of common siding.

In drop siding, which are frequently used, there is an exposed edge of about half an inch, and about one-fourth inch more surface on the moulded edge than there would be if it were flat, making a total gain over flat surface of three-fourths of an inch on each piece of siding, or eighteen and three-fourths per cent. Hence eighteen and three-fourths per cent. should be added to the dimensions in square feet of the side of a building to get the actual surface measurement for drop siding.



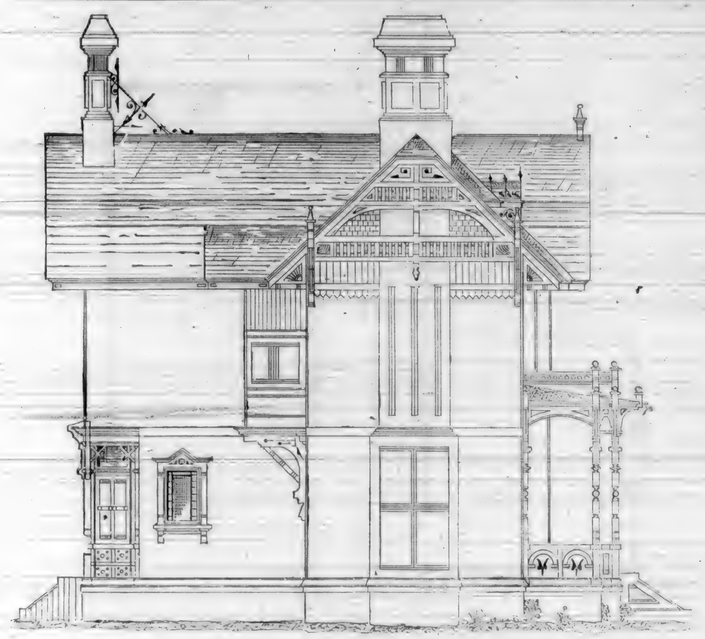
FIRST STORY PLAN OF $2,500 COUNTRY DWELLING.

In measuring the gable ends of ordinary buildings, the dimensions should be one-half less than actual square measure. For instance, the end of a building is twenty feet wide, and it is ten feet from the level of the frame plates to the point of the roof, multiply the width, twenty feet, by one-half the height, five feet, and we have one hundred square feet, total surface of gable end. This rule will not apply to buildings with very steep roofs, nor to cottage structures with a number of small gables.

Measurement of sides of buildings solid without deducting openings, like doors and windows, would probably average well as a basis for determining the quantity of paint required. Windows vary in size, and some frames and casings are elaborate in design, while others are quite plain. For good-sized windows, with very plain frames, about one-third less than solid would be a safe calculation; while for others, with heavily moulded caps and wide casings, with perhaps narrow openings, a solid surface estimate might fall a little short. These variations must be duly considered and calculated for by the painter. Cornice and trimmings should be measured separately. If there are panels with beads and other projecting and receding features, brackets, etc., carefully measure one of each, count the number on the building and multiply by the dimensions of one, and the product will be the total dimensions. Open brackets on cornices and scroll and lattice work on verandas, should be measured solid, as the edges fully make up for open spaces. The utter lack of uniformity in house trimmings compels more or less reliance upon the judgment of the painter in measuring them. We can suggest no rule for measuring which can be used with satisfactory results in all cases. What would be admirably suited to one building would be wholly unadapted to another, simply because the architectural features are unlike. Here there is no alternative but to exercise judgment in considering these important features.

In calculating the quantity of paint required upon the basis of surface measurement, from twelve and one-half to forty per cent. should be allowed for trimmings, etc., according to their size and shape. For plain work from fifteen to twenty per cent. will be found a fair average. This depends, however, upon the number of windows, style of frames, etc. We do not announce this as a positive rule.

On Queen Anne structures, which are



SIDE ELEVATION OF $2,500 COUNTRY DWELLING.

painted with two or three body colors, and are burdened with numerous and elaborate trimmings, calculation must be made of the portions of the buildings to which the different body colors are to be applied, either by divisions of total measurement, or by separate measurements, and the trimmings considered separately.—*The Painter.*

The Art of Picture Hanging.

How to hang pictures so as to prevent their killing each other or being killed by their surroundings has ever been a difficult matter. In a collection it is impossible that all the pictures should be hung in a row nearest the natural range of light. Yet even having this manifest advantage, killing is frequently effected by adjacent contrasts of color. It is related of Turner that he did not consider his labors over when he had sent his pictures to the exhibition; he would wait until the hanging committee had done its work, and then on varnishing day would by a few magical touches so alter the tone of his work that all the neighboring canvases looked like foils carefully arranged to set off this one particular picture in the whole room. "He had been here and fired off a gun," said Constable on one occasion, when he found that the introduction, at the last moment, of a bit of scarlet into a gray sea-piece of Turner's had completely absorbed the color of his own picture.

For home decoration great care is required in the hanging as in the purchase of pictures. In selection the purchaser must be guided first by the size of the room. What appears mellow and harmonious in the great gallery will seem full of harsh outlines and discordant blotches of color when hung in the modest parlor where proper focal distance cannot be obtained. The size of the room and the color of the room must not violently contrast with the color of the picture. For instance, if a painting rich in reds and yellows of a tropical sunset is hung in a room lacking in bright color, its reds and yellows will glare with terrible fury; and a picture which is subdued in tone will have all its depth of color absorbed, leaving it gray and chalky, if placed in a position with warm surroundings. Even if picture and room are in complimentary tints, there is an art in hanging so that the painting may appear at its best. Generally this effect is produced when it is hung against the wall on a line nearest the natural range of eye. A second picture placed above this line may be tilted also, that the light of day should fall on the same angle as the pictured lights. That is, if the light in the picture appears to come from the right-hand side, the real light should likewise come from the right-hand side. Attention to these details may appear trifling to one who knows nothing and cares little for art, but the care extended will be amply repaid to them in the restful effect gained, while to the cultured, even mediocre pictures may be made to bear a charm that will make their possession a joy forever.—*Cincinnati Building Review.*

The Pavement of Workshops.

DR. KOCHLIN-SCHWARTZ notes the existence among certain workmen on the ground floors of factories, of a distressing though not painful œdema of the legs, which seems to be dependent in no way upon gout or rheumatism. The disease has only existed since the wooden flooring formerly in use was removed, although now the workmen have shorter hours and live under vastly superior hygienic conditions. The workmen themselves attribute this swelling of the feet and legs to the nature of the pavement. They dread especially asphalt, then cement, next comes stone flagging, and finally bricks, which they prefer to any of the others. It does not seem to be a simple question of standing upon a cold floor, since the brick pavements are as cold as the cement or the asphalt. If there be really any relation here of cause and effect, the evident lesson would be that wooden floors should always be preferred to the more modern style of pavements.

PUBLICATIONS RECEIVED.

Hints on Drainage and Sewerage of Dwellings, by William Paul Gerhard. It has been the author's aim in this new work to give an account of the usual condition in which plumbing work, done years ago—and some done quite recently—may be found, and also to give suggestions on the proper manner of doing the work. Beautifully illustrated, and should be in the hands of every one who desires a thorough knowledge of sanitary matters in connection with their dwellings. **Price $2.50.**

Cummings' Architectural Details. A few copies of this publication on hand. **Price $6.00.**

Modern House Painting. A new edition of this popular work just received. It is much superior to its predecessor. **Price $5.00.**

Plummer's Carpenter's Guide, being a handbook for workmen, also a manual of reference for contractors, builders, etc. **Price $1.00.**

Practical Carpentry (new). Price $1.00.

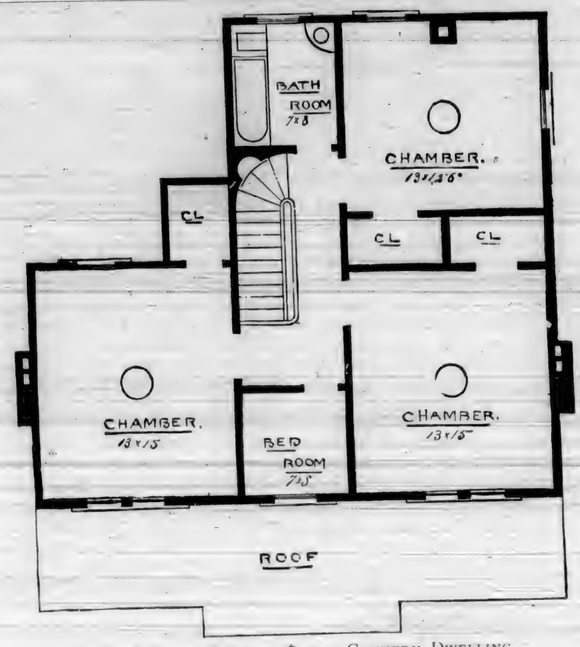
Artistic Coloring on Exteriors.

THE profession of house painting is gradually assuming its proper position in art, but it moves very slowly. This is especially true of that branch of it which pertains to exterior painting. Many painters pay little or no attention to the combinations of color they use on such work, but leave the selection entirely to customers, a course which has many objections. Few of these customers are practical painters, and hence are incompetent to select the colors required to make their buildings look symmetrical and artistic. The painter should get a customer's idea of what he wants and then use his knowledge and judgment in making the proper combination. If a customer thinks some color is not correct which may be proper, pleasantly prove to him it propriety, and he will be satisfied and places confidence in the painter's ability and judgment. But if painters persist in yielding every point, through fear of giving offense, they can hardly expect to win the confidence and esteem due to competent workmen. I do not mean that the painter should be dogmatic, or that he should attempt to inforce radical or impracticable views of coloring upon those who may seek his advice; but that his knowledge of the business he follows should be so thorough that

any suggestion he may offer will be entirely consistent with true standards of excellence.

I have seen many houses painted with good combinations of color, which looked poorly on account of the surroundings. The painters employed not having sufficient range of vision to take in the surroundings, the buildings were painted without due consideration of them. This is a common defect. I have also seen houses placed very close to each other, without the accompaniment of lawn or shrubbery, all painted about the same, which is in bad taste. Supposing these houses were painted with a very good combination of colors, the taste displayed is still defective; for a variety of good combinations, one helping the other, would be much better, give better satisfaction to the occupants, and please the passers-by. But supposing the occupants of this row should all decide upon having their houses painted the same color—say, for instance, an olive color—it is quite an easy matter to have them allow of a shade of difference in the color used, provided it is called olive. Now, make one house a little more of the yellow than another, the next a little greener, and another with a brown cast, and by so doing, some of the buildings appearing cool, others warm, and so placed that one is complementary to the other, a very much better effect is obtained than would be the case if all were painted exactly alike. Even in business blocks it is preferable to paint with different combinations of color, as one color helps another, and the peculiar color of a store becomes identified in the public eye with the business and the location. Let a painter but hint at the advantage of this style of coloring as a means of advertising, and see how readily he will be allowed to have his own way.

Another class of houses which has been sadly neglected as to artistic painting is farm-houses. They are generally painted, if at all, simply with a view to the preservation of the wood without respect to artistic appearance. If there is any one place more beautiful than another in this world, it is a well-cultivated farming district dotted with artistically painted farm-houses. The farmer not being an artist, this part of the beautifying process devolves upon the painter, and for humanity's sake, as well as the advancement of his business, he ought to do his best, as there are few men who like to show off their houses, especially if they are beautiful, better than the farmer. There are combinations of color which may be used with good taste on houses in a crowded city, which would be absurd on a farm-house. In painting such a house the sky should be taken into consideration as well as the other surroundings. Houses on the north and east sides of the road or under the cool aspect of the sky, should be painted a warmer hue than those on the south or west sides or under the warm aspect. A house which has elevated land for a background, should be painted a warmer hue than one which has the sky for a background. If olive colors are used, they should be light and of a warm cast. The light, bright, cheerful colors are preferable, as they are in strong, pleasing contrast with nature, which surrounds them on all sides.



SECOND STORY PLAN OF $2,500 COUNTRY DWELLING.

In cities and towns we find many wooden houses situated beside brick buildings, and sometimes between two such buildings. In such cases it is proper to paint the house so situated with a cool color, like olive, bluish gray or any other cool shade that will contrast well with the warm color of the brick house next to it. Where there is a row of dwelling houses to be painted, it is a good plan to paint them in different colors, alternating warm and cold. For instance, paint one red, another olive, another citrine, another of a bluish color, and so on until all have been painted, so as to make a good combination of the completed job. If painted in this way they will look well collectively, and each house will be made to look well by contrast, provided all are arranged as they should be.

There are a few artists among house painters, but the majority of them seem to know very little about the harmony and contrast of color, and what they do know they have learned intuitively from working among colors, not by hard study and experiment. No painter, no matter how good his taste may be for color, can make perfect combinations without making a life study of the subject. In years gone by the study of color has been sadly neglected, especially by those men who are most benefited by it. But the present seems to be making up for lost time. Nearly every scientist and mechanic who knows anything about color is studying and writing for the benefit of others, and the painter of to-day who does not study and read all he can find written on the subject of color, will in a few years find himself far behind the majority of the men working in the house painting business.—*The Painter.*

How Shot Are Made.

A SHOT-TOWER is an immense brick structure, 150 feet high, resembling a light-house more than anything else. Visitors are conducted up a spiral staircase inside, to the top, where a fine view is obtained for miles about, but the view down the inside is not so pleasant. The opening where the shot descends becomes narrower and narrower, until nothing is seen at the bottom but darkness. At the top of the tower are the furnaces for smelting. From these lead is poured into pans, set in the tower, with perforated sheet iron bottoms. The melted lead comes through these holes and enlarges on the other side, forming into globules before it falls down to the well beneath, holding several feet of water. The large shot drop the whole height of the tower to the bottom, but the smaller sizes only about half as far. One peculiar thing is, that small shot generally expand in falling, and the larger sizes contract. Very great care is necessary in mixing the metal, as it would run through the holes and drop in strings if not of the proper proportions, and no shot could be made at all.—*The Manufacturer and Builder.*

Band Saws.

We have recently received from M. Dugoujon Aine, of Paris, a very useful article, giving "Directions for the proper way of using and sharpening band saws." We print it below, for the benefit of our readers, together with the illustrations, which will enable the reader better to understand the directions:—

Considering the many difficulties that have arisen in the use of band saws, "arising for the most part from an imperfect knowledge of how to treat them, we think it not out of place to give a few instructions on this point, the observance of which we judge indispensable to obtain satisfactory results in working. The first thing required of band saws is that they should not break. Band saws, as a rule, do not break because they are too hard, or of inferior quality, or too strong or too weak; but they break because the tooth is an unsuitable one. It is important to make use of such teeth only as from their form will best adapt themselves to the action of rolling and unrolling from one pulley to the other. It is found that it is only every other tooth that breaks, and especially when they are like those shown in Fig. 1.

Fig. 1.

This is accounted for by the fact that the teeth, when set, produce upon the pulleys the same effect as a chain does when running edgeways on a pulley; that is, instead of adapting itself to the pulley and forming a regular curve, it forms a number of short, straight lines as shown in Fig. 2. Each one of

Fig. 2.

these straight lengths out of the regular curve is sufficient to cause a break.

We have said that all sharp angles prevent the proper running of the saw round the pulley, and that the only teeth that are not likely to break are those with the bottom or angle well rounded. It is a very easy matter to make teeth suitable for all kinds of wood and yet fulfil these conditions, as, for instance the tooth shown in Fig. 3. This tooth, when

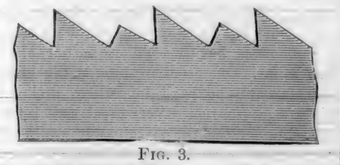


Fig. 3.

properly sharpened, no matter what the size of tooth or space between them, will fulfil the required conditions, whereas 90 out of 100 sawyers will sharpen as in Fig. 4. In this

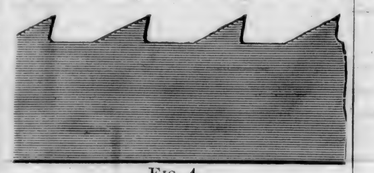

Fig. 4.

case, by the routine of the workmen, the sharp angles are reintroduced, as also the consequent liability to break. But on the contrary, by keeping up the form of tooth shown in Fig. 3, the saw, when heated, will easily stretch without breaking, as the edges present no sharp angles; besides which, the saw adapts itself more easily to the pulley on account of the wide space between the teeth, and so, again, is rendered less liable to break.

As an example to show how easily anything having a sharp angular cut in it will break, you have only to take an ordinary square made of iron, brass, or steel, and pull it in opposite directions by its two extremities, and you will always find it break at the angle, as in figure 5. The same effect is produced on a band saw; it runs downwards, and, the wood being held firm, offers a resistance in the opposite direction; thus the tooth is pulled in the same manner as the square, and, like it, will break at the angle.

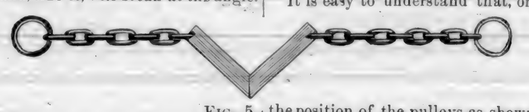

Fig. 5.

In order to keep up the shape of the teeth to Fig. 3, the best way is to grind the bottom of the wide spaces with an emery wheel, equalizing them with a smooth file, and to sharpen the points with a file. Or a diamond-shaped file may be used, as in figure 6. By either of these two methods the use of band saws may be rendered much less difficult and troublesome. Numbers of persons use band saws without having any idea as to the conditions required of the machine to insure proper working, so we will just note them down:—

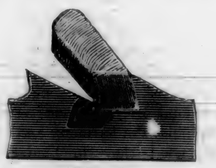

Fig. 6.

1. The diameter of the pulleys should be as large as possible, being however in proportion to the work to be done. 2. The two pulleys and the two guides should be kept perfectly parallel one with the other. 3. The two axles of the pulleys, on the contrary, should be a little wider apart at the front of the machine than at the back, as shown in Fig. 7. 4. In order to run well and easy the back of the saw should always be close up to the flange of

Fig. 7.

the pulley. On this account, and in order to pass smoothly through the guide, it is very important that the saw should be well dressed at the back, but not straight, for a well-made saw is slightly hollow on the back (see Fig. 8).

It is easy to understand that, on account of the position of the pulleys as shown above, the saws should have a corresponding curve. Saws made in the manner indicated, and maintained in the same state, make the work very much easier; the saw wants less stretching and gives a better result, and consequently requires less power for a greater amount of work. By

Fig. 8.

taking care always to use saws sharpened by good workmen and to keep them well sharpened, it will be found that, instead of increasing expense, a great saving may be made, caused by the consequent avoidance of breaks and by the better work and greater amount produced.

One of the most important points in a band saw is a good joint. The following is the best way of making it. First file slightly the two ends to be joined, in order to take off any grease or other foreign matter that may be upon them, but without making them any thinner. Then lay one end over the other as in Fig. 9 and 10, and keep them in their places with two bits of iron wire. Then tie on very fine brass wire, which sprinkle over with borax, after it is bound. Then melt the brass by means of a special forge for the purpose, or with brazing tongs, or with gas

by means of a blow-pipe. But in this last case it would be necessary to have special bellows *ad hoc*, which is not always an easy matter for every one to establish. Brazing tongs will suffice for saws up to 1¼ in., but as a forge is required to heat the tongs, it would be better to use a forge with a double blast, so arranged as to soften only just as much as is necessary for brazing the joint. When the brass is melted, let the saw cool without putting it into water, then tap the brazed part lightly with a hammer, to loosen and shake off the borax; and, lastly, reduce the joint to the same thickness as the rest of the saw, either with a file or an emery wheel.

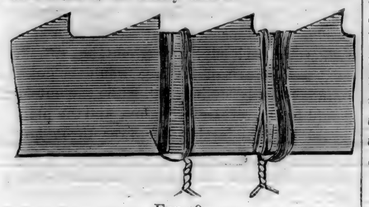

Fig. 9.

M. Dugoujon, in conclusion, states that he has patented a special grinding machine for finishing these joints. By means of this machine the joints can be made much better

and in much less time than with a file, and the expense of the emery wheels is incomparably less than that of files. This same machine with a thinner emery wheel is very useful for gulleting circular saws and for sharpening band saws.—*Timber Trades Journal.*

Removing Spots from Gilt Frames.

Gilt frames are liable to become spotted and look bad, while it is, as a rule, difficult to remove the spots. Rubbing does not answer, for the stain sticks tighter than the gilding itself, and washing is liable to loosen the gilt if put on with gum or dextrine.

The *Papier Zeitung* recommends the following method of renovating gilt frames. It consists in applying with a camel's hair pencil a gum solution to which has been added gold bronze having the color of the frame. Before mixing with the gum water the bronze must be washed with water until it runs off perfectly clear. If one application does not suffice it may be repeated until the spot entirely disappears, but of course one coat must be dry before the next is applied.

Spots treated in this way look very well at first, but it will not last, for it is not able to resist the moisture in the air unless it is specially prepared. For this purpose an ordinary bristle brush is rubbed with a piece of yellow wax until it is somewhat sticky, then it is passed very lightly over the spot several times as when dusting it. This gives it a very thin coat of wax that hardens in two or three days; in the meantime it must be protected against dust.

New Publications Received.

"Hints on Household Tastes." By Chas. L. Eastlake.

A new edition of a popular work by an author that is known in nearly every civilized portion of our globe. We quote from the author's preface the following:—

"Fifty years ago an architect would have considered it beneath his dignity to give attention to the details of cabinet work, upholstery, and decorative painting. But I believe there are many now, especially among the younger members of the profession, who would readily accept such commissions if they were adequately remunerative, and that they might become so is evident from the fact that the furniture of a new house frequently costs as much, if not more, than the house itself. *And when clients lead the way we may be sure that manufacturers will seek assistance from the same source.* Price, $3.00, post paid.

"Album of Mantels, in Wood, Stone, Slate, and Brick."

This new work contains sixty large plates, containing designs for mantels of every description in wood, stone, slate and brick. The author is C. C. Buck, architect. We will mail a copy of this work to any address upon receipt of $5.00.

"Drainage and Sewerage of Dwellings." By Wm. Paul Gerhard.

In this work the author shows the difference between the way plumbing work is done now and that of years ago. All the improved systems of sewerage are clearly illustrated and explained. The advantages and defects of different traps for wash-basins, sewers, water-closets, etc., are treated in an intelligent manner. The book should be in the hands of every one who desires a thorough knowledge of the sanitation of dwellings. Price, $2.50.

"The Air We Breathe and Ventilation."

This book is the second number of the Mott series. The aspirating system of ventilation has been presented to the exclusion of other systems which have been proposed, for the reason that the writer considers the principle on which that system is founded to be correct. Price, $1.50.

"History of Architecture in all Countries from the Earliest Times to the Present Day." By Jas. Furguson.

This work is one that should be in the possession of every architect. Especially should students and draughtsmen secure a copy. Being a reprint of the London edition the price has been materially reduced. Two large volumes, containing over 1,200 pages, beautifully illustrated. Price, complete, $15.00.

"Building Superintendence."

This new work is of invaluable assistance to the architect and builder. It is written by a gentleman long connected with the architectural profession, and is eminently practical in its character. We will send a copy to any address upon receipt of $4.00.

"Buck's Designs in Architecture."

This new work contains over seventy pages of designs for country dwellings, together with plans and estimates of cost—the latter according to New York prices. Allowing for the difference in price of material, a fair estimate may be made for which the design selected could be built on this coast. Price, 50 cents.

"Peck Bros. Illustrated Catalogue and Price List."

This is the finest catalogue we have yet received in the way of presenting a complete list of all the articles used by the plumber and gasfitter. It also contains all the new designs in brass goods, and a very complete representation in the line of copper, iron, and earthen ware, water-closets, traps, etc., etc. It contains about 600 pages, beautifully and artistically illustrated, with the price of each article in all the different sizes. It is issued by Peck Bros. and Co., of New York, R. W. Snow being the general agent on this coast.

Our Exchanges.

We have made arrangements with the editors of the following journals, by which we are enabled to offer quite a reduction to any one subscribing for any one of them in connection with this journal.

(The figures in parenthesis denote the price of the journals alone.)

California Architect and Building News.
Terms, $2.00 per annum.
With *American Architect* ($6.00), $7.00 per annum.
With *Builder and Wood Worker* ($1.00), $2.50 per annum.
With *American Artisan* ($1.00), $2.50 per annum.
With *Brick, Tile, and Metal Review* ($1.00), $2.50 per annum.
With *Building* ($1.00), $2.50 per annum.
With Special Edition of *Building* ($5.00). $5.75 per annum.
With *Scientific American* ($3.20), $4.50 per annum.
With *Decorator and Furnisher* ($4.00), $5.00 per annum.
With *American Machinist* ($2.50), $4.00 per annum.
With *Cincinnati Building Review* ($1.00), $2.50 per annum.

Theophrastus, a Greek writer who flourished in the fourth century before the Christian era, in a work entitled the "Book on Stones," describes an earthly substance which would kindle and burn, and which was used by smiths. There can be no doubt that he refers to coal, and that this is the earliest passage in which that substance is expressed or mentioned.

A man's labor, well applied, is always amply sufficient to provide him during his life with all things needful to him, and not only with those, but with many pleasant objects of luxury, and yet, further, to procure him large intervals of healthy rest and serviceable leisure.

Steel Sinks.

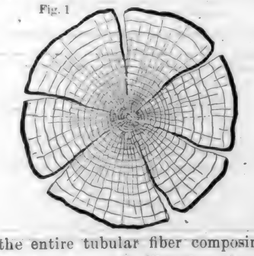
Examine the advertisement on page 8 of this issue in regard to these valuable adjuncts to the conveniences of the kitchen.

How Lumber Shrinks.

A STORY is told by the "Arkansaw Traveler," about the manner in which lumber was "hauled" across the mountains down in his country. "Why!" said he, "they saw it green, leave it in the sun, and off it starts. I have seen a board turn three summersaults in less than a minute, and get to the other side of the mountain before sunset." "What," asked a by-stander, "would be the result if it was attacked in its wild career by a shower of rain, would it come back?" Here was a poser, but the traveler was equal to the occasion and replied: "No, it would turn on the other side and continue its course."

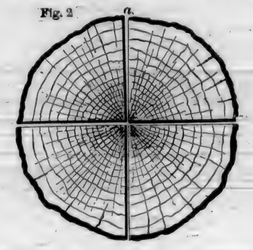
The subject of the contraction of lumber is an interesting one to wood-workers, and the doors and shutters in many of our mushroom cities are said to come off the hinges in retaliation of the persistent disobedience of the natural law of shrinkage. An examination of the end of an oak or beech tree will show the arrangement of its structure. It consists of a mass of longitudinal fibrous tubes, arranged in irregular circles, that are bound together by means of radial strings or shoots, which have been variously named; they are the "silver grains" of the carpenter, or the "medullary rays" of the botanist, and are in reality the same as end wood, and have to be considered as such, just as much as the longitudinal woody fiber, in order to understand its action. From this it will be seen that the lateral contraction or collapsing of the longitudinal, porous, or tubular part of the structure cannot take place without first crushing the medullary rays, hence the effect of the shrinking finds relief by splitting in another direction, namely in radial lines from the center, parallel with the medullary rays, thereby enabling the tree to maintain its full diameter, as shown in Fig. 1.

Fig. 1



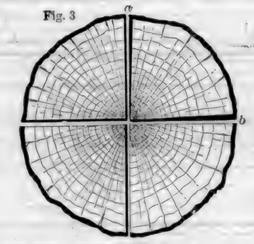
If the entire tubular fiber composing the tree were to contract bodily, then the medullary rays would of necessity have to be crushed in the radial direction to enable it to take place, and the timber would thus be as much injured in proportion as would be the case in crushing the wood in the longitudinal direction. If such an oak or beech tree is cut into four quarters, by passing the saw twice through the center at right angles, before the contracting and splitting have commenced, the lines $a\,c$, and $c\,b$, in Fig. 2 would be of the same

Fig. 2



length, and at right angles to each other, or, in the technical language of the workshop, they would be square, but, after being stored in a dry place, say for a year, it would then be seen that a great change had taken place both in the form and in some of the dimensions; the lines $c\,a$, $c\,b$ would be the same length as before, but it would have contracted from a to b very considerably, and the two lines $c\,a$ and $c\,b$ would not be at right angles to

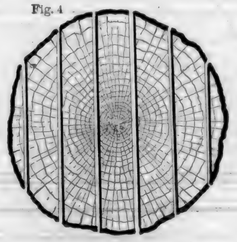
Fig. 3



each other by the portion here shown in Fig. 3. The medullary rays are thus brought closer by the collapsing of the vertical fiber.

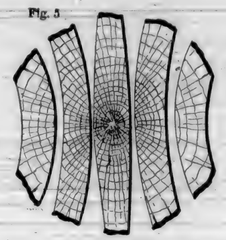
But supposing that six parallel saw cuts are passed through the tree so as to form it into seven planks, as shown in Fig. 4, let us see

Fig. 4



what would be the behavior of the several planks. Take the center plank first. After due seasoning and contracting, it would then be found that the middle of the board would still retain the original thickness, from the resistance of the medullary rays, while it would be gradually reduced in thickness toward the edges for want of support, and the entire breadth of the plank would be the same as it was at first, for the foregoing reasons, and as shown in Fig. 5. Then taking the planks at

Fig. 5



each side of the center, by the same law their change and behavior would be quite different; they would still retain their original thickness at the center, but would be a little reduced on each edge throughout, but the side next to the heart of the tree would be pulled round or partly cylindrical, while the outside would be the reverse, or hollow, and the plank would be considerably narrower throughout its entire length, more especially on the face of the hollow side, all due to the want of support. Selecting the next two planks, they would be found to have lost none of their thickness at the center, and very little of their thickness at the edges, but very much of their breadth as planks, and would be curved round on the heart side, and made hollow on the outside.

Supposing some of these planks to be cut up into squares when in the green state, the shape that these squares would assume, after a period of seasoning, would entirely depend on the part of the tree to which they belonged; the greatest alteration would be parallel with the medullary rays. Thus if the square was near the outside the effect would be as shown in Fig. 6, namely, to contract in the direction

Fig. 6

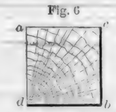


Fig. 7

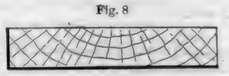
from a to b, and after a year or two it would be thus, as seen in Fig. 7, the distance between c and a being nearly the same as they were before; but the other two are brought by the amount of their contraction closer together. By understanding this natural law, it is comparatively easy to know the future behavior of a board or plank by carefully examining the end of the wood, in order to ascertain the part of the log from which it has been cut, as the angle of the ring growths and the medullary rays will show as in Fig. 8.

Fig. 8



A plank that has it will evidently show to have been cut from the outside, and for many years it will gradually shrink all to the breadth. While the next plank, shown in Fig. 9, clearly points close to the center or heart of

Fig. 9

the tree, where it will not shrink to the breadth, but to the varying thickness with the full dimensions in the middle, but tapering to the edges, and the planks on the right and left will give a mean, but with the center sides curved round, and the outside still more hollow. These remarks apply more especially to the stronger exogenous woods, such as beech, oak, and the stronger firs. The softer woods, such as yellow pine, are governed by the same law, but in virtue of their softness another law comes into force, which to some degree affects their behavior, as the contracting power of the tubular wood has sufficient strength to crush the softer medullary rays to some extent, and hence the primary law is so far modified. But even with the softer woods, such as are commonly used in the construction of houses, if the law is carefully obeyed, the greater part of the shrinking, which we are all too familiar with, would be obviated, as the following anecdote will serve to show: It was resolved to build four houses, all of the best class, but one of the four to be pre-eminently good, as the future residence of the proprietor. The timber was purchased for the entire lot, and the best portions were selected for house No. 1, but by one who did not know the law, and to make certain of success this portion of the wood had an extra twelve months' seasoning after it was cut up. The remainder of the wood was then handed over to a contractor for the other three houses, who had an intelligent young foreman, who knew the structure of wood, as well as how to obey the law, and who, therefore, had the wood for the three houses cut up in accordance therewith. The fourth house was built the following year by another man; but long before ten years had passed, to the great surprise and annoyance of the proprietor, it was found that his extra good house had gone in the usual manner, while the other three houses were without a shrinkage from top to bottom.

A similar want of correct knowledge of the natural figure and properties of the structure of wood, such as the oak, is constantly shown by the imperfect painting to resemble that wood, as exhibited on doors and shutters of many houses. If we cannot afford to have genuine wainscot doors, as in France and other countries, but yet desire to have an imitation, it should surely be worth the trouble to have a block cut from the quarter of an oak tree, and to have each of its six sides planed and polished, in order to make plain their several features. The house painter would then see what nature really is, and thus save us from the ridicule of other nations, when we mix up "silver grains" and all the other natural features on one side of a board or panel. This is a subject that should interest all wood-workers and builders, and a great deal of attention should be given to the structure of the various woods. It is almost as necessary for a wood-worker to understand the anatomy of his tree, so to speak, as a surgeon to understand human anatomy before he commences to operate. The importance of the subject is therefore obvious.—*The Lumber World.*

*. We are indebted to the editor of the *Lumber World*, published in Buffalo, New York, for this article, as well as the cuts illustrating the same. It is with pleasure that we acknowledge the professional courtesy extended. Trade Journals in every portion of the country, are increasing in influence, and the one from which we produce the above should be found in every Mechanic's possession. The knowledge gained will far over-balance the small amount of money required for a year's subscription.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co's. SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING FEBRUARY 5, 1884.

292,987.—SELF SHIPPING BELT PULLEY—H. P. Christie, S. F.

292,992.—ALARM SIGNAL FOR HOT JOURNALS—Cornelius & Turner, Turner, Oregon.

292,900.—VEHICLE GEAR—W. A. Dawson, Stony Point, Cal.

292,910.—CAR COUPLING—J. M. Harper, Colfax, W. T.

292,932.—STEP LADDER—E. Markwick, Pinkney, Cal.

293,069.—HYPOTENUSE CALCULATOR—Daniel Patten, Calistoga, Cal.

293,087.—HORSE POWER—A. Robinson, Benicia, Cal.

293,093.—SCARF RETAINER—J. Sandilands, S. F.

293,104.—SPADING MACHINE—D. F. Spangler, Santa Ana, Cal.

293,130.—SAW—Geo. W. Wills, Portland, Oregon.

293,208.—GRASS COLLECTOR FOR LAWN MOWERS—J. H. Wyms, Oakland, Cal.

FOR WEEK ENDING FEBRUARY 19, 1884.

293,931.—TABLE FOR MANUFACTURE OF CANDY—C A Alisky, Portland, Oregon.

293,841.—FRUIT PITTING MACHINE—Chas. Alison, S. F.

293,932.—DREDGER—H. B. Angell, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Brick Fronts.

THE overwhelming desire for a "neat job" has done mischief in brick work. A pressed brick wall is a monotonous thing when brick is used alone. It shows only mechanical precision and exactness, and these qualities become very tiresome when they are exhibited for their own sake and not as means to an end. A slight unevenness in texture and in color helps the look of a wall, and it is the aim of the maker of pressed brick and of the builder to avoid the slightest unevenness. The best-looking brick walls, except in the perverted eyes of bricklayers, are those in which the unevenness appears, that is to say, those which are built, not of pressed bricks, but of common bricks, chosen for color.—*New York Record.*

Bound Volumes of this Journal, $2.50.

The "California Architect" is now in the Sixth Year of Publication.

Competition Designs!

ONE HUNDRED AND FIFTY DOLLARS

Cash Premiums!

FOURTH PRIZE,

Box of Drawing Instruments.

In order to promote a general desire to excel among Architects and Draughtsmen in the preparation of drawings for this Journal we have concluded to offer the following premiums for the best 4 designs of a Country Dwelling, the successful plans to be published in the CALIFORNIA ARCHITECT AND BUILDING NEWS.

1st, a Cash Prize of $60.00
2d, " " 50.00
3d, " " 40.00
4th, Box of Drawing Instruments.

Notice to Competitors.

All plans to be in the office of the CALIFORNIA ARCHITECT ON OR BEFORE the 1st of May, 1884.

All plans not accepted will be subject to the order of the owner, and will be returned upon receipt of the necessary postage.

We claim the right to reproduce in this journal all drawings of which honorable mention is made, and yet not entitled to a prize.

A *non de plume* to be used on all drawings; a letter to accompany the latter, addressed with the name used, containing also the real name and address of the contestant. This is done solely that the person's name and residence will not be known until the committee have made the awards.

A scale of ½ inch to the foot to be used.

Detailed estimate of cost to accompany the drawings. QUANTITY and PRICE of each material used to be given, so that allowance can be made for difference of price between the various sections of the East and this Coast.

Drawings are to show front, rear, and side elevations, with plans of the different floors.

The value of the house when finished to be ABOUT FIVE THOUSAND DOLLARS.

This competition is open to Architects in every portion of the United States.

Drawings to be made on card or bristol-board; to be line shaded; NO color but JET BLACK to be used.

All competitors will receive one year's subscription to this journal FREE, that they may see the various plans adopted.

The merits of the various designs will be decided by a committee appointed by the San Francisco Chapter of Architects.

All inquiries in regard to the above will be answered by addressing a letter to the office of this journal, 240 Montgomery St., San Francisco.

WOLFE & SON, Editors and Publishers.

Harold D. Mitchell.

THIS gentleman may be justly termed a California educated architect; for, although the principles of the art were first studied in England, it was in this city that he applied them to the practical workings of the profession.

Mr. Mitchell was born in the town of Manchester, England, on the seventh day of April 1854. He early developed a taste for art, and, after passing through a collegiate course, he entered the ROYAL INSTITUTE OF ART in his native city. In this school his ideas and conceptions were moulded in a form in keeping with the high standard adopted by the Faculty.

His aspirations leading him to secure a more extended knowledge of architecture, as practised in different parts of this world, in 1870 he embarked for San Francisco. Shortly after his arrival in this city, he secured an engagement in the offices of Messrs. Wright & Sanders, and for eight years remained with that firm.

Having a strong desire to build up a business on his own account, in 1878 he severed his connection with the firm in which he had so long been engaged, and commenced business on his own account. His personal popularity, aided by a well-earned skill as a designer, enabled him at once to start a lucrative practice, and his success was commensurate with his ability.

Mr. Mitchell has designed many prominent buildings, among which are St. Luke's Church, Court House at Merced, the warehouse of Falkner, Bell & Co., the large buildings used by the Central Gaslight Co., etc.

HAROLD D. MITCHELL.

Mr. Mitchell's business has greatly increased since the beginning of the year, and he has been compelled to seek larger quarters. His offices are now in the Safe Deposit Building, and are fitted up in artistic style. He is a member of the San Francisco Chapter of Architects.

Window Ventilation.

NO TIME could be better than the present for beginning the practice of house ventilation by the window, which is still, in the majority of houses, the readiest and the safest means of obtaining a regular and constant supply of fresh air. The practice, begun in warm weather, may be carried on with proper care through autumn and winter. The constantly accumulating impurities derived from breath, from perspiration, from excreta of other kinds collected in sleeping-rooms, from the use of gas or lamplight, and too often, even now, from suction of sewerage gas from waste pipes by the heat of house fires, etc., render it as necessary for health as for comfort that these should have free egress, and that they should be substituted by the pure outer air. Fresh air from without may very easily be had without draught, and without risk of cold even to delicate persons if a few simple rules be observed. The cold air of winter, of course, enters with greater force and in greater proportional volume than the more equal summer air into a warm room. The aperture of ingress must be correspondingly diminished. Air from a window is preferable to that from an open inner door, no matter how roomy the house, from its more reliable purity. If the window be the inlet, the fire, fire-place, or it may be the door of a room in summer acting as an outlet, it may be opened from the top, the extent being regulated according to the outer temperature. There is then a direct inward current at the upper part, which follows the roof of the room, thus mingling with any heated waste products which require to be removed, and an interrupted current at the middle, the previous line of junction of the upper and lower sashes; both are broken and diffused by the blinds or curtains. Venetians for this purpose should be turned upward. A window should never be made to ventilate by opening it from below, unless the open lower space be filled up in some way and ventilation be carried on at the middle where the sashes join—otherwise draughts are unavoidable. The ventilating pane is a hardly less simple and equally efficient and safe method with either of the others. Window ventilation is especially useful in bedrooms, and its efficiency or otherwise cannot fail to affect the vital powers of the occupant, who, in his slumbers, must trust to other energies than his own for the removal of those impurities and morbific germs which his every breath multiplies around him.

Removing Spots From Gilt Frames.

GILT frames are liable to become spotted and look bad, while it is, as a rule, difficult to remove the spots. Rubbing does not answer, for the stain sticks tighter than the gilding itself, and washing is liable to loosen the gilt if put on with gum or dextrine.

The *Papier Zeitung* recommends the following method of renovating gilt frames: It consists in applying with a camel's-hair pencil a gum solution, to which has been added gold bronze having the color of the frame. Before mixing with the gum water the bronze must be washed with water until it runs off perfectly clear. If one application does not suffice, it may be repeated until the spot entirely disappears, but of course one coat must be dry before the next is applied.

Spots treated in this way look very well at first, but it will not last, for it is not able to resist the moisture in the air, unless it is specially prepared. For this purpose an ordinary bristle brush is rubbed with a piece of yellow wax until it is somewhat sticky, then it is passed very lightly over the spot several times as when dusting it. This gives it a very thin coat of wax that hardens in two or three days; in the meantime it must be protected against dust.

THE largest saw-mill at Port Blakely, W. T., was put to a test of its capacity one day a week or two ago. The whole cut of the day was 283,000 feet, the largest previous day's work being 224,000 feet.

A. A. Cook.

AS STATED in previous issues, it is not our intention to present a likeness of merely those who belong to the Chapter. We propose to give the history of all those on the Pacific Coast that are recognized as members of the architectural profession. Many have written to us, expressing their good-will to our Chapter, and regretting that distance prevented them from attending Chapter meetings. To all such we would say, You can help, no matter how great the distance, by your pecuniary assistance, as well as forwarding papers to be read, submitting sketches, etc., and the Chapter will gladly welcome those to membership whose character is of a high standing, and whose architectural ability is recognized by his fellow-brethren.

A. A. Cook, the subject of this sketch, is a resident of the city of Sacramento. He was born in Chenango County, New York, on the 20th day of April, 1832. In May of the same year, his parents moved to Albany, in which place he received his first lessons in the practical workings of the carpenters trade. In 1848 he was apprenticed to the carpenters and joiners trade.

It may be interesting to our young mechanics of to-day to know the value of apprentices' wages forty years ago. The first year Mr. Cook received $50.00, the second year $75.00, and the third year $100. In those days, however, a three-years' apprenticeship, if the student was faithful, enabled him, at the expiration of the time, to readily assume the duties of an "old hand."

We find the result, in the present case, of the value gained by the appropriation of every minute of time during youthful days. In winter months, a prominent architect gave Mr. Cook instruction in practical geometry and architectural drawing, and, also, thorough his influence, enabled Mr. Cook to gain access to libraries containing works on architecture and carpentry. In those days books treating on those subjects were very rare. The works thus obtained were faithfully studied, and their principles fixed in his mind.

He also showed an aptitude for the art and science of hand railing, and such was his proficiency that, while still under twenty years of age, we find him giving instructions to a class of young mechanics.

In 1851 Mr. Cook moved to Kalamazoo, Mich. For nine years he was one of the prominent builders of that place; every spare moment was given to the study of the profession which he had selected for his future business. After visiting several places, we find him located in Council Bluffs. In this town he began strictly the architectural profession, and several prominent buildings were designed by him, including the largest hotel, at that time, west of Chicago.

His health failing about this time, and, hearing of the great salubrity of the climate in California, he started for this coast, and arrived in Sacramento in 1869. The benefits derived from the change soon proved that the journey was a wise one, and, in a short time, Mr. Cook was fully restored to a robust state of health.

A. A. COOK.

Although residing in Sacramento, Mr. Cook's practice extends over a great portion of the northern part of the State. Nevada also can show many buildings erected under his superintendence.

Mr. Cook possesses one of the finest and most complete architectural libraries to be found in any private office on this coast. He is always ready and willing to give instruction to the younger members of the profession, and students can always be found in his office, learning the principles of the science of architecture.

EXPERIMENTS have shown that a person speaking in the open air can be heard about equally well at a distance of 100 feet in front, 75 feet on each side, and 30 feet behind.

The Lumber Trade—Order Your Lumber.

DEALERS report "trade entirely satisfactory." But verbal statements in this connection are not necessary. The inaudible voice of hundreds of buildings in progress of erection, and the excavations being made in all parts of the city, proclaim the fact that materials are in demand in large quantities, and that those who manufacture and sell those suitable for building purposes, must be enjoying a corresponding degree of business activity. We say yet to those contemplating the erection of buildings requiring more than ordinary sizes and lengths of timbers, to pass in their orders as soon as practically possible, as extra dimensioned timbers cannot, as a rule, be found in our lumber yards in stock; consequently, as all such extra lumber will have to be cut to order, time may be saved by ordering early, as delays frequently occur in the transportation from mill to wharf—the winds and weather being very material factors in that connection. We have sometimes had orders filled within three weeks, under most fortuitous conditions, and in other cases, and, as a rule, from four to ten weeks. If a wharf at the mill should break down, as sometimes they do, and mix up ordered and stock lots of lumber, or if the vessel happens to meet a "stress of weather," or is beached, or runs on a reef, or bar, etc., more or less time is lost, and sometimes considerably *more*. Hence it is wise to order early, and order all that will be wanted, for if "everything is left to the last moment," it places matters in such a shape as to make them unpleasant; for when an order is sent from this city by a lumber dealer, he can do no more than say: "Hurry up," "expedite," etc., while the *doing* part is in other hands, and often the man at this end is helpless to remedy delays, at which excited and perhaps angered owners, architects, and contractors complain, and sometimes say naughty words.

Beautiful Finishes.

HARDWOOD finishes are the most lasting and beautiful that can be applied to a building. In California, the great expense attending their use debars many people from placing the same in their homes. Redwood, when properly prepared, and covered with Wheeler's Patent Wood Filler, cannot be told from the genuine hardwoods, except by an expert. This preparation should be used by every one who desires a lasting and beautiful finish.

Brooks As Sewers.

WHEN a natural watercourse traverses a town, and its banks become built upon, the easiest way of getting rid of filth and house wastes is to throw them into the stream. Every man's instinctive impulse is to get rid of what annoys him, and not to mind how his neighbor will be affected. After a while, when the watercourse becomes sufficiently nasty, the people come to a realizing sense of what they have brought upon themselves, and then they try to devise a remedy. In this they begin usually at the wrong end. They look on the stream as creating the nuisance, and don't consider that it is their abuse of the stream that is the source of the trouble. So they go to work and cover the stream up, and call it a sewer. What is the result? Simply that the stench of the foul matter in the old channel is bottled up somewhat, to be vented through every manhole, every inlet, and every house drain, and probably do more real injury than when the rotting filth was exposed to the air and the sun, and diffused its aroma through the whole atmosphere.

The channel of a small natural stream through a town or village should never be converted into a sewer for house wastes. This will strike a good many people as an odd doctrine. The functions of a natural stream and of a sewer are so diverse that one cannot be made to do duty for the other.

A natural watercourse serves for the drainage of the land all along its course. Its banks cannot be made water-tight without obstructing the natural progress of the water in the soil and backing it up and retaining it where it ought not to be retained. A sewer, on the other hand, is intended to carry off foul matters which must be gotten rid of as quickly as possible, and the channel for conveying them must be absolutely impervious, so that nothing can soak through it to the soil. As the level of the water in the soil rises and falls with the season and the amount of rain, an open-jointed or pervious channel would sometimes admit water from the soil and sometimes permit fluids flowing in the channel above the level of the ground water to flow out, and thus pollute the soil and the air in the soil.

Again, a natural stream draining a considerable territory is subject to great variations in its volume. A channel to carry its extreme discharge in floods must be many times larger than can ever be necessary for the carriage of the greatest amount of sewerage that can be brought to it. A large channel is not suited to the rapid removal of a small flow of filthy fluids, and, moreover, costs a great deal more than a sewer of the proper size. Even if the large channel for a fluctuating stream is built through a village, the sewerage from the houses should not be turned into it, unless the minimum volume of the natural flow in the driest seasons is large enough to keep the channel thoroughly scoured. There are a good many small towns which have for years gotten along without sewers, and have arched over natural watercourses, running through them, but are now impelled by the "sanitary revival" to construct sewers for removing household wastes. The first impulse is to utilize the covered streams to save the expense of constructing a few hundred feet of sewer. They should be very careful how they proceed. It is better to spend a little more money and be safe than to economize in the first cost and spend ten times the saving in doctors' fees and undertakers' bills.—*Sanitary Engineer.*

Educating Plumbers.

TRULY this is an age of progress, and in more ways than one. Take, for example, the question of education. Not very many years ago even good, skilled artisans could not make out a time-sheet and give a correct return of work done and materials used, but had to dictate to a clerk or other responsible person. This did not matter where men were working in communities, as in those cases there was always some one in charge to keep a proper record; but where they were working singly, it may seem far-fetched to say, but it really amounted to one man doing the work, and another had to keep an account of what was done; yet these men, perhaps, were first-class mechanics as far as workmanship goes. But the present generation have advanced considerably in this matter, thanks to the interest taken and the schools established, and now there are very few men who have not a fair knowledge of the three R's—that is, reading, 'riting, and 'rithmetic. Now, with this knowledge, the average working-man has grown to be more intelligent, it is true, but it is an open question if he is a better tradesman; and, as a proof of this, do we not continually refer to what was done ages ago as works of art, and also of construction, and hold up for admiration the work of our forefathers? But for all that the working-man is still the working-man; it is still the muscle that is required to do that which machinery fails to accomplish, so that in reality he is a piece of machinery. He has brains, it is true, but they only work in certain grooves in which they have always traveled. Ask a plumber why he warms the piece of lead that he may be working upon; he will answer, "*To soften it, to be sure, and make it easier to work;*" but ask him why heat softens the lead, and how many could answer? Again, ask him why he greases the prepared ends of a pipe before making a joint, and he will answer, "*To make the solder stick;*" there are exceptions, of course, but from the average tradesman no better answer would be given.

This age has always been referred to as one of progress, and one of the innovations of the age is "technical education." About this there is a diversity of opinion; some look upon it as an actual necessity, while others think it of no use or advantage. In using the term "technical education," it is meant in this case in the popular sense, in which a practical trade and all its cognate science subjects are taught together.

Germany, France, and Switzerland have for some years past taught various sciences in the same schools and concurrent with the ordinary education of youth, but it must be remembered that those countries depend mostly upon the productions of their industrial classes, so that "the more highly they are educated, the better for the country." But England, having such enormous natural resources, has not made the same progress in technical education as the countries mentioned, but the want of it has been felt, and efforts are now being made to make this movement more popular.—*James Mullens, in Sanitary Engineer.*

Care of Patterns.

ONE of the largest expenses of the producers of cast metal articles from toys to machinery is that of patterns. These must be made of the finest stock and by the most skilled workmen. All patterns are made originally of wood, which in the case of light articles are exchanged for duplicates in metal at once, just as the wood block for engraving is exchanged for the stereotype or the electrotype. But large patterns, as for beds for lathes, planers, and other heavy machines, and many other articles, must necessarily be of wood in permanence. How to keep these patterns in good condition when not in constant use has been a puzzle to many, but moisture proof as well as fire proof buildings have filled that demand. A greater annoyance and anxiety is caused by the difficulty of classification and arrangement, so that any particular pattern may be found at once. Where the patterns are limited to a certain stock of reproduced machines, it is easy enough to arrange the patterns in suits each part of a completed machine to be kept in one compartment. But where the demands on a foundry are of a miscellaneous character, it is impossible to keep a referable list with ordinary classification.

A shrewd manufacturer has overcome this difficulty by adopting the alphabetical order of the dictionary, a name being given to each pattern and piece when made, and entered upon a kept dictionary in the office, another, a duplicate, being kept in the pattern house. Illustrations might be given to show how the thing works, but this is not necessary. It is sufficient to say that under a single letter, G, there are no less than 200 entries, but all so distinct and discriminated that no difficulty is found in locating them in their alphabetical departments, or in charging them to each handler, as pattern room, foundry, or designing (draughting) room. By the addition of numerals to the alphabetical plan it is easily seen that any number of convenient subdivisions may be made.—*Scientific American.*

Science of Carpentry Made Easy, Price, $5.00.

Detail Cottage and Constructive Architecture, Price $10.00.

MASONS' and BUILDERS' EXCHANGE OF SAN FRANCISCO,

Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

Brick Wall Disfigurement.

THE extensive use of red bricks which has been made of late years for houses and public building has caused a good deal of attention to be directed to a curious disfigurement to which such structures are liable, in the form of a kind of white mould which is apt to creep over their surfaces. The best of buildings are quite as subject to this detraction from their appearance as the worst, the new Technical College at South Kensington, for instance, being just now covered in places with this objectionable kind of eruption, which is not very generally understood, and for which no remedy has yet been found, we believe, except time. An American paper publishes one or two scientific opinions on the matter, one being that of Dr. Leidy, president of the Academy of Natural Sciences. According to this authority, the white efflorescence is simply ordinary Epsom salts, or sulphate of magnesia, and the production of it on brick surfaces must be regarded as evidence of the presence of sulphurous acid in the air, the result of coal-burning. There is magnesia in the mortar with which the walls are built, and there is sulphurous acid in the air, and in the presence of moisture a chemical combination takes place, the result being sulphate of magnesia. This dissolves in the rain and runs down over the bricks, and evaporation leaves the white deposit. Another chemist agrees that this is the way in which the efflorescence is produced, but thinks that it is potash with which the sulphurous acid combines, and that the white is sulphate of potash, while another authority considers it to be sulphate of lime. All agree, however, that it is the sulphurous acid in the air which causes this disfigurement, and this is really the important aspect of the matter. If this is the effect of atmospheric impurity on brick buildings, it seems reasonable to suppose that it must be somewhat serious in its influence on human lungs.—*Building Times.*

Some of Ruskin's Maxims.

WORK is only done well when it is done with a will; and no man has a thoroughly sound will unless he knows he is doing what he should, and is in his place.

It may be proved with much certainty that God intends no man to live in this world without working; but it seems to me no less evident that he intends every man to be happy in his work.

It is no man's business whether he has genius or not; work he must, whatever he is, but quietly and steadily; and the natural and enforced results of such work will be always the things that God meant him to do, and will be his best.

No book is worth anything which is not worth *much;* nor is it serviceable until it has been read, and re-read, and loved, and loved again, and marked, so that you can refer to the passages you want in it, as a soldier can seize the weapon he needs in an armory.

Building Operations in Yolo County.

ALREADY the sound of the saw and hammer is beginning to be heard—and right merrily, too—in many of the interior counties. Messrs. Gilbert & Son, one of the principal contracting firms of Woodland, have kindly forwarded us a complete list of building operations in their neighborhood. No notice is taken of improvements less in value than $1,000. The number of these would fill the entire pages of this Journal. We intend—from time to time—to give full reports from the principal sections of the State.

Woodland and Vicinity—Main and College Avenue. Additions to three-story brick. O., W. M. Coward; A., W. H. Hamilton; C., W. H. Curson; cost $4,500. Third Street and Oak Avenue. One-story frame. O., G. Lambert; B., Glenn & White; cost $1,200. Main Street. One-story frame. O. and B., G. K. Glenn; cost $2,650. Elm Street. One-story frame. O., H. Shuluck; B., Glenn & White; cost $1,100. Main Street, Odd Fellow's Hall, alterations and improvements. C., G. W. Myrick; cost $1,500. Sprague Avenue. One-story frame. O. and B., Mr. Irwin; cost $2,200. South Fifth. Three-story frame. O., J. T. Wallin; B., Gilbert & Son; cost $3,500. North Street. One-story frame. O. and B., Mr. Anderson; cost $1,300. College Avenue. One-story frame. O., John Jacobs; B., Porter & Sponge; $1,500. College Avenue. One-story frame. O. and B., Broderick Bros; cost $2,800.

West Woodland—One-story frame. O., M. Antone; B., A. Pool; cost $1,200. Third Street. One-story frame. O. and B., M. Wilson; cost $1,000.

East Woodland—One-story frame. O., Armstrong & Akre; cost (days work) $1,100. Second Street. One-story frame. O., Dr. A. Aken; B., J. A. Blake; cost $1,200.

Capay Valley—Two-story frame. O., A. Winters; C., W. H. Winne; cost $3,500. Capay Valley House and stable. O. and B., E. Thomas; cost $1,100.

Davisville—Two-story frame hotel. O., J. T. Lillard; days work, $4,000. Clayton Avenue. One-story frame. O., G. Harris; C., Pool & Sears; cost $1,000.

PRACTICAL CARPENTRY.

PRICE $1.00.

A guide to the correct working and laying out of all kinds of Carpenters' and Joiners' work. Solutions of the various problems in Hip roofs, Gothic work, Centering, Splayed work, Joints, Hinging, Dovetailing, Mitering, Timber Splicing, Hoppers, Skylights, Raking mouldings, etc. This work should be in the hands of every mechanic. One of the features to which this book will undoubtedly owe its success, is the absence of those numerous formulas which serve only to confuse the ideas of so many workmen. Everything is written in a clear, concise, and practical manner, and its utility is brought within the grasp of those workmen who have not had the benefit of a school education. We will send the above work to any address upon receipt of $1.00.

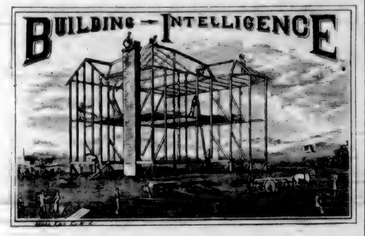
NEW EXCHANGES.

Wood and Iron. A new journal, devoted to those interests represented by its name. Its typographical appearance is very fine, and it promises in its editorial department to equal many of its competitors that are now old in the field of journalistic enterprise. Published by S. L. Everett. **$2.00 per year.**

The Painter. An illustrated monthly devoted to painting and decorating, now in its third year. Typographically, *The Painter* is unusually neat and tasteful. It should be in the hands of every painter. Published at Cleveland, Ohio. **$1.00 per year.**

Every architect in the State should insert his professional card in our columns, and thereby prove that he is endeavoring to assist in building up an architectural journal that will take rank with any printed. The charge is small. We want the influence your names will give, and we promise to spare no efforts in making the "California Architect" fully represent the views of a majority of the Profession on this Coast.

BUILDING — INTELLIGENCE



SAN FRANCISCO.

California, near Larkin. Two-story frame.
O.—W. Coe.
A.—Wolfe & Son.
C.— — Klatt.
$4,500.

Sutter, near Stockton. Additions.
O.—C. A. O. D.
A.—Wolfe & Son.
C.—Hatfield & McRae.
$1,000.

Church, near Twenty-first. Two-story frame.
O. and B.—C. Kleebauer.
$3,000.

Church, near Twenty-second. One-story frame.
O.—T. Shields.
C.—J. P. Shephard.
$2,500.

Twenty-first, near Chattanooga. One-story frame.
O. and B.—F. Buckley.
$1,600.

Hoff Avenue, near Seventeenth. Six French flats.
O. and B.—W. Fletcher.
$10,000.

Mission, near Ninth. Two-story and base frame.
O.—Swedish Evangelical Lutheran Church.
A.—B. E. Henriksen.
Day's work.
$10,000.

Battery, near Pacific. Two-story and basement brick
O.—J. Musto.
A.—W. H. Bayless.
C.—G. Richardson, B. W.
$25,000.

Twentieth, near Noe. Two-story frame.
O. J. Scheerer.
Day's work.
$7,000.

Second Avenue, near Sixteenth. Two-story and basement frame.
O.—Mr. S. Kelley.
C.—W. F. Muller.
$3,400.

Michigan, cor. Sierra. One-story frame.
O.—Toomay & Farrell.
Day's work.

$14,190.

MISCELLANEOUS.

San Jose—Third, near Empire. One-story cottage. O., F. S. Montgomery; A., Theo. Lenzen; C., W. B. Mitchell; $1,400. Market, cor. Colfax. One-story cottage. O., L. Rothermel; A., Theo. Lenzen; C., Thos. Clark; $4,000.

San Rafael—Depot for S. F. & N. P. R. R. O., P. Donahue; A., Theo. Lenzen; day's work; $15,000.

Santa Rosa—One-story brick. O., G. E. Grosse; C., T. J. Ludwig; $3,500.

Hemacite Knobs.

THE Gordon Hardware Co. have now a large assortment of these knobs on hand. For interior work they are superior in design to any knobs in the market. They are fully guaranteed for strength and durability. Those wishing an illustrated catalogue can secure one by addressing the above firm, or the manufacturers, the Dibblee Manufacturing Co., Trenton, N. J.

PROPOSALS FOR THE CONSTRUCTION
OF THE
New Odd Fellows' Hall.

SEALED BIDS WILL BE RECEIVED AT THE OFFICE OF The Odd Fellows' Hall Association of San Francisco, Room No. 1, Odd Fellows' Hall, No. 325 Montgomery street, San Francisco, up to and until 12 o'clock M., of

FEBRUARY TWENTY-SEVENTH, 1884,

For the erection of the New Odd Fellows' Hall, on the lot on the southwest corner of Market and Seventh streets. Bids to be received for the separate trades, as follows:

No. 1—Brickwork.
No. 2—Carpenters' and Joiners' Work.
No. 3—Granite and Freestone Work.
No. 4—Cast Iron Work.
No. 5—Wrought Iron Work.
No. 6—Tin and Platers' Work.
No. 7—Plumbers' and Gasfitters' Work.
No. 8—Plasterers' Work.
No. 9—Painters' and Glaziers' Work.

The plans and Specifications of said building can be seen at the office of Messrs. Wright & Sanders, No. 418 California street, and will there be open to public inspection after the date hereof.

The successful bidders will be required to furnish bonds, satisfactory to the Board of Directors, for the faithful completion of the work in accordance with the plans and specifications. The Board of Directors reserve the right to reject any or all bids.

C. T. PIDWELL, Secretary
of the above-named Association.

San Francisco, January 25, 1884.

THE brickmakers of this country last year consumed three million cords of wood, the product of fifty thousand acres of average timber land. A large part of this immense expense could have been saved, with a proportionate increase in the profits, by the use of improved methods in firing.

TERMS:
PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.
Back Cover, outside, each insertion, $2.00 per square.
Page preceding reading matter, $1.75 per square.
Page following reading matter, $1.50 per square,
Inside Pages, each insertion, $1.00 per square.
Full Page, inside, one insertion, $40.00.
Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

OUR COMPETITION PLANS.

This will be the last notice sent to those desiring to compete for the prizes offered by the Proprietors of this Journal.

All designs and plans must be at this office on or before May 1, 1884.

Those received by that date will be presented before the Committee of the S. F. Chapter at the regular monthly meeting on May 2d. Each and every contestant will be notified of the decision of the Committee as soon as possible after the awards are made.

Particular notice is given to those residing out of this State to send their plans so as to reach this office by the time specified.

Building Improvements.

THE GENERAL OUTLOOK IN THE STATE.

THE indications point strongly to extensive building operations in all sections of the State.

One of the surest signs of a most prosperous and busy season is the

ACTIVE DEMAND FOR DRAUGHTSMEN:

That has lately sprung up from different sections of the country. From the extreme southern portion of our State telegrams have been received by us for first-class draughtsmen. After diligent inquiry, we have failed to find good men who were willing to accept the situations, although from $80.00 to $100 per month was offered, and steady work guaranteed.

The effect of the late storms has been the circulation of an immense amount of money through the southern section of the State. It is calculated that over one million of dollars will be expended in repairing damages. This large sum and that received from the assured large crop, will cause very extensive operations in building and mechanical lines.

Los Angeles leads all the counties in the number and value of buildings erected, followed very closely, however, by Alameda County. In the former county, numerous towns are springing into existence, offering superior inducements to young men to migrate into neighborhoods where muscle combined with head work, properly exercised, will lay the foundation of a prosperous future.

Fresno and Tulare have been asleep for a while, but when harvest time comes along no doubt they will regain their former business prosperity.

The counties bordering on the bay are all sharing a large degree of prosperity, and, from present indications, large improvements will be carried out during the year.

Sonoma, Napa, and Marin,—thanks to an energetic race of inhabitants, stand very prominent in the list of go-ahead counties More work is now being talked of than there are mechanics numerous enough to meet the labor demands.

The counties north of Sacramento are awakening from their sleep, caused by a partial failure of crops last season, and each and every one will be heard from when the time of the saw and the hammer begins.

IN THIS CITY

Never were indications for a grand building season more pronounced than they are at the present time. Up to the 10th of April buildings and improvements of the value of

OVER TWO MILLION DOLLARS

Have been commenced. This is greater than the entire amount for the whole year of 1880.

We sincerely hope that the prospective activities will not be checked by increase in the prices of building materials, or excessive demands by mechanics for high wages. It is far better and wiser that the prices of material and rates of wages should be steady and reasonable, and a fair degree of business continuous, rather than a rush for short periods, followed by dullness and inactivity during a considerable portion of the year.

San Francisco Chapter American Institute of Architects.

THE regular monthly meeting of the Chapter was held on Friday eve, April 4, 1884. President John Wright presided. Committee appointed to procure a Seal for the Chapter, reported that they had attended to their duties, and now had the pleasure of presenting the Seal to the Chapter. A short recess taken to allow the members to inspect the same.

Upon motion it was resolved that the *design* of the Seal be accepted. This motion was carried, with the understanding that the committee have two weeks further time, in order that improvements could be made by the engraver in portions of the dies.

The committee were also requested to place the Seal in the hands of the committee on incorporating the Chapter, by the time agreed upon, so that at the next regular meeting the incorporation of the Chapter may be a settled fact.

The collector appointed by the Chapter, on motion, was allowed 10 per cent. on all collections.

Committee on preparing articles of indenture for students was granted further time.

The committee upon the applications of members proposed at previous meeting was allowed till next regular meeting to make their report.

Proposition for membership was received from J. J. Clark, and referred to Messrs. Sanders, Wolfe, Jr., and Pissis.

Committee on the different classes report favorable progress by pupils. Adjourned.

Be Sure That Your Figurations Are Correct

THAT which is of first importance to contractors and those estimating the cost and value of material and labor required in the erection of buildings, etc., is correct figuring. Every mistaken figure below true value is a direct loss in the amount represented by the figures in error. Hence the importance of men understanding how to figure, the value of figures, and the most perfect method of using them. Sometimes errors result from absolute or imperfect knowledge of the science of figures and figurations; sometimes from failure to comprehend the extent and magnitude of the thing estimated upon; sometimes a spirit of recklessness and disregard of the involvments, a don't-careativeness as to the results, a chance-taking disposition and frame of mind, which, if it happens to settle down upon a safe conclusion, does so from sheer "it happened so;" and some are thoughtless, desiring and aiming to be right, but, from lack of mental energies and fixedness of thought, fail to take in and deliberate upon all the matters of cost, and so fail to be near right.

It seldom happens that where ten more or less competent contractors estimate upon a building or works of any kind, that very great incompetency and lack of mechanical intelligence and right understanding, or something less creditable, are not illustrated, in perhaps five out of ten being inconsistently high; perhaps three, more or less, below a correct amount, and one or two at a sum fairly and reasonably remunerative. It is no strange matter to find from ten to one hundred per cent. difference in ten bids. Sometimes the estimates will run together, except it may be the very low man or two who have failed to add in all the items of cost. But the more general rule is great differences in amounts.

The effect of all this is injurious to contractors, as intelligent owners do not generally take in the situation and recognize results from the contractors standpoints, but reasonably set it down to questionable intent or want of proper knowledge. We say reasonably, for when ten or five men, recognized, practical contractors, submit estimates running from the low man, say at $4,500, and the high man, $7,500, or, as in one case in our office, the low man being less than $40,000, and the high man, $60,000, argues decidedly unfavorably to those who make such discrepancies; yet it is not always the case that the low man is loser by his undertaking; sometimes he is, and many hundreds of thousands of dollars have been lost to material, men, and others, from this cause, but we have good, faithful men who have run through years of contracting without failure, and have something to show for their labors, who have worked almost continuously upon contracts taken as the lowest bidder.

Every foot or pound of material, and every hour of labor, according to quality and kind, possesses a standard value, furnishing, to those using them, all the requisite elements to correct conclusions; so that when more than reasonable differences occur, the presumption is sustained that there has has been a lack of good judgment, or a superabundance of carelessness, or ignorance indulged in.

For, with the defined basis of calculation, such as exists in the market, and purchasable value of materials, and the well-understood cost of labor to quantity of materials required, there is but a small right margin for variations in total costs, when handled by intelligent and competent parties.

Eastern Comments On Our Bone Yard Article.

THE *American Lumberman*, in commenting favorably upon our "Bone Yard" article which appeared in the February number of this journal, remarks: "At this distance it is hard to judge correctly of the condition of the lumber trade in San Francisco; but it does seem that with a tariff of only $2.00 per 1,000 feet on lumber, the manufacturers on the Canadian side of Puget Sound, ought to be able to sell lumber at a profit, if the scale of prices fixed by the Association are as outrageously high as stated by the ARCHITECT."

True—"distance" does render it difficult for parties who have never visited, nor been able to inform themselves by personal observations as to the lumber market of San Francisco, and the manufacture of lumber at Puget Sound, to rightly understand the peculiarities of the situation. And when inside facts are revealed by publications, as in the matter in question, they appear so different in character from the more usual and better regulated markets of the country, that even those engaged in little business in other cities and places cannot readily comprehend the actual facts as they exist.

As to the suggestion of our cotemporary, in reference to the tariff of "only $2.00," it is correct, provided there could be any assurance to British Puget Sound manufacturers, that present prices, and the prices ruling for the past two years, could be maintained.

But the fact that American manufacturers hold the key to the lumber market of this coast, and have it in their power to control and regulate the prices under a united and firm combination, it would be consummate folly for any one to risk the uncertainties; for just as soon as a competitive supply of imported lumber should be placed on the market, our wide awake combination men would tumble the prices to ruinous rates—unless they could house the competition—and the imported material would have to be sold at a loss.

This fact is so well understood that men with capital, seeking investment, give the matter no serious consideration, because the field is too treacherous. We can at any moment control $1,000,000 for investment in lumber mill operations on the British side of Puget Sound, if there were any reasonably fair show of a steady market for lumber at present prices for even five years.

But the chances are all the other way. It was only in 1877-78, that the very men who now hold control of the market by combination, were in merciless competition among themselves, and the same lumber, Oregon pine, that is now retailing at $22.50, sold retail then at and for less than $12.00 per thousand feet; at which price, however, there was but bare salvation from ruin generally, while a few were crippled, and some compelled to surrender under the then too severe pressure. But when prices recovered to $14.00, $15.00, $16.00 a feeling of safety pervaded the lumber market, and manufacturers and dealers felt that they had reached safe ground.

Under this state of facts our contemporary may easily see the difficulties of competition by lumber taxed with a tariff of only $2.00, for the general building of the coast, being altogether of wood, the amount of lumber required to supply demands is large, and the American manufacturer could comfortably afford to sell at a profit of $2.00 per thousand until British competitors tired of selling at actual cost of production with $2.00 tariff added.

Pioneer Hall Competition.

NAMES OF CONTESTANTS.

Below will be found a correct list of the names of the Architec's presenting plans for the proposed Pioneer Building. We withhold comments until after the award shall have been made.

PERCY & HAMILTON,
WRIGHT & SANDERS,
MCDOUGAL & SON,
A. LAVER,
HOFFMANN & O'CONNOR,

SHARP-CORNERED DRAWING TOOLS.—A sensible correspondent of the *American Machinist* very justly complains that "manufacturers of drawing instruments make them so full of little sharp corners, and interior angles," and suggests that they be made "of round or oval cross sections, with no places where dirt can collect." The trouble is that makers of drawing tools very seldom, if ever, have any practical experience in the use of such instruments, and are unknown to those who have.—*Mining and Scientific Press.*

GILDED FRAMES.—To restore gilding to picture frames, etc., remove all the dust with a soft brush, and wash the gilding in warm water, in which an onion has been boiled; dry quickly with soft rags.

Compiled Items of Interest for Mechanics.

THE weight of a crowd of men closely packed is estimated at 84 lbs. per superficial foot.

Street, Store and Bank Fronts $4.00

IT is thought by many that a girder—say 12x16—will bear more weight if it is ripped through the middle, making two pieces 6x16, and these two be reversed and bolted together again. This is an erroneous conclusion. The only advantage gained is, that, by the process given, an opportunity is presented to examine the center of the timber, which, in large pieces, is often in a state of decay; also, it gives the timber a better opportunity to become seasoned, and thus less liable to rot.

Cottages and Villas $6.00

TIMBER when wet has only about half the strength of the same timber when perfectly seasoned.

Builder's Guide $2.00

DOUBLE tenons are often used in Joinery, but should be avoided in Carpentry, as they weaken the timber into which they are framed; both tenons seldom bear equally, so that a greater strain is thrown upon one of them than it is intended to support.

Modern Perspective $6.00

EVERY mechanic should be able to cut and frame all timbers, rafters, etc., upon trusses on the ground. Many, however, have not studied the rules of Carpentry sufficiently to be able so to do. To such we would say that it will greatly benefit you to secure a copy of "Mechanic's Geometry, or The Science of Framing by the Aid of Card Board Models." This eminently practical work—if properly studied, and the principles put into practical use, will enable a mechanic to frame any portion of a building with ease and exactness. But few copies can now be had of this work, as the edition is exhausted. Sent to any address upon receipt of $5.00.

Wooden and Brick Buildings $18.00

EDITORS ARCHITECT: In a bill of lumber, lately received, I find the item—72 pieces 2x6 for *Raglins*. Please inform me of the meaning of the term *Raglins*.

LUMBER DEALER.

Your customer is evidently a newcomer. *Raglins* is a term used in England for ceiling joist.

The Artisan $5.00

ONE of the most practical works for the mechanic to have in his possession is "The Science of Carpentry Made Easy." A copy will be forwarded to any address upon receipt of $5.00.

Universal Assistant $2.50

A SCHOOL-TEACHER asks for a simple method of preventing reverberations in a school-room. Instead of the ordinary smooth plaster finish for the walls and ceilings, have the same rough finished. Curtains may be used for the windows instead of blinds. Large maps hung around the room, aside from being ornamental, are very useful as anti-reverberators.

Church Architecture $4.00

IN many journals different measurements are given in *meters*. Mechanics can easily compute the same in *feet* by allowing 39⅜ inches to a *meter*.

Plaster, how to make it $1.00

FIVE pounds of nails are required for 1,000 shingles, when laid 4 inches to the weather.

Buck's Practical Designs 50c

BOUND volumes of this Journal are becoming scarce, and those that desire the same should immediately forward $2.50, for which a copy will be sent to any address.

Practical Carpentry $1.00

WOOD screws vary in size from one-sixteenth to three-eighths of an inch in diameter, and in length from one-fourth to three and a half inches, including twenty-three numbers, as follows:—

Length.	Number.	Length.	Number.
¼	0 to 2	1⅛	9 to 18
⅜	2 " 7	1¼	10 " 20
½	2 " 9	2	11 " 20
⅝	3 " 10	2¼	11 " 20
¾	4 " 12	2½	14 " 20
⅞	6 " 12	2¾	16 " 20
1	7 " 14	3	15 " 20
1¼	8 " 16	3½	18 " 22

Number 11 is about three-sixteenths, and Number 14 about one-fourth of an inch in diameter, and are sizes in very common use.

IT requires 123 sheets of tin 10x14 to cover one square, and 59 sheets 14x20 to cover same space.

Cummings' Architectural Details $6.00

A HANDY thing to have on a farm is a measuring cord with which to measure off acres. To make one, procure sixty-seven feet of strong rope, one inch round, make a loop or fasten a ring or bar at each end, and make these exactly sixty-five feet apart. This is four rods. Then tie a piece of red rag in the center. One acre of ground will be a piece four of the cords (chains) long, and two and one-half wide, equal to sixteen by ten rods, making one hundred and sixty square rods to the acre. The advantage of the ring or loop is that one person can measure alone by driving a stake in the ground to hold the rope while he stretches it out. The rope should be soaked in tar and dried, which will prevent its shrinking when wet.

Steel Square and its Uses $1.00

Bancroft's Histories.

THIS magnificent work embraces a complete history of the Pacific States. The territory covered is the western half of North America, from Panama to Alaska, including all of Central America and Mexico, and is equivalent in area to one-twelfth of the earth's surface.

There are to be thirty-nine octavo volumes, with maps and illustrations, fifteen of which are now ready. They will be well printed on good paper, neatly and substantially bound, uniform in style, and will average over 700 pages each. Three or four new volumes per annum will appear until the entire series is completed. Subscribers will not be obliged to take the work unless it corresponds with the description in every particular.

	Per Volume.
Bound in Extra, English Cloth, neat and attractive style	$4.50
Bound in fine leather, Library Style	5.50
Bound in half calf, half Russia or half Morocco	8.00
Bound in Russia Leather or Tree Calf	10.00

Any information in regard to the above will be given by addressing the office of this Journal.

New York Letter.

BY A. CURTIS BOND.

It is a difficult task to undertake the study of American architecture, difficult, because it leads to no satisfactory result. Here, architectural art, like every other matter that is regarded from a business view, is developed under a strictly speculative influence, and "time" is accepted as one of the appreciative qualities. Human activity is a powerful factor in the appreciation of human works.

Nor does this unfortunate artistic condition appear to be easily remedied, or even susceptible of future correction, for the rapidity of our life, and, consequently, of the execution of our designs, makes it impossible, even for the coldest and most analytic talent from foreign countries, to resist the tendencies of our climate, and avoid cultivating the same disposition himself. This second atmosphere of our country at first stifles the new-comer, and he pities the disposition to "rush things," but as he meets others more, and finds that he is falling behind in the race, he bestirs himself, and, before he becomes conscious of the influence, he is measuring time in his labors, and falls into the true American scheme, of making a *melange* of everything and allowing it to take the place of a creation.

Yet this failing of our architectural art must not be accepted as a general condemnation, for we admit all the very best examples of foreign work with this indiscriminate adaptation and a Greek, Moresque, and Persian form may be found as next door neighbors in our streets and squares. It serves to enliven and diversify the city, and furnishes subjects for visiting foreigners to return to their homes and write about, and against. New York may be accepted as the type of American cities, I presume, yet there is a greater variety of architecture here than elsewhere over the continent. The peculiarity of which I have spoken is shown here in a marked degree.

This disposition, however, to utilize all the old styles, and combine oddities into one building, has had another good effect in giving us very many peculiar and decided original structures, picturesque in the extreme and interesting to study.

One building recently put up has the heads of the architect, the builder, the owner, and a variety of other persons interested, more or less, in its completion, arranged at various points, on the gable, from the tops of the windows, at the end of the waste pipes, from the roof, and in several other places equally inappropriate, and equally conspicuous. Another building imitates the Bastile, and is reduced to the humble purposes of a storage house. A new residence is an excellent reproduction of a baronial castle, on a small scale, with a moat, portcullis, and watch-tower, sentry box, and all. Another still, the house of a prominent physician, is a rambling, low, Queen Anne structure, full of odd and queer corners, a marvelous quantity of stained glass, and a multitude of picturesque chimneys.

One of the growing men of our Eastern States, one who is so young, and so well known as to warrant the belief that he will make himself more widely felt, as he increases in age and in experience, is Mayor Seth Low, of Brooklyn, just re-elected to another term of office, and at the same time reached his thirtieth birthday.

Mr. Low has a great deal of originality, and has shown it in the house that he has put up, or rather reconstructed from a small and dilapidated cottage. The style of the building is the Queen Anne, of red brick, with terra cotta trimmings, a color and combination that is rather marked, amid the surroundings of substantial brown stone. The stoop is of large, manufactured stone slabs, and on either side grass plots laid out, in goodly sized squares, and unprotected save by a simple sub-base of stone. The pillars and roof of the entrance are of a dark green, carved wood, and the vestibule of variegated marble, and the door of light, polished oak. A bay window on the side (the house is upon a corner), has for ornament an enormous square waste pipe, leading from the roof and which branches off into two at the roof of the bay window, coming down then upon either side to the ground. This pipe is a capital imitation of terra cotta, and is probably the first really successful attempt to make such a thing as this decorative.

An oddity, in every sense of the word, is being put up at Coney Island. Ever since Barnum brought Jumbo to the country, that interesting animal has been counterfeited in every conceivable manner, and the designation for the stupendous of every sort was the word Jumbo. Finally this craze has extended to building, and now they are putting up, at Coney Island, a restaurant, dancing hall, and the usual accompaniments, to be contained in a structure shaped like an elephant, the legs to be spiral stairs, the head a music room, and the body to be divided into the restaurant and the ball room. The height of the animal is to be eighty feet, and the length, one hundred and twenty-five. If this scheme is enlarged upon, and the white elephant which is expected from Europe daily, should be found worthy of a similar monument, and when it extends to other animals in the show, it may entirely change the architectural aspect of our watering-places, and they may put on the appearance of monstrous out-door menageries, gatherings of the creatures that populated the world before the flood.

* * * * * * *

The illustration that I have chosen this month is that of a country house, of a conglomerate style, somewhat on the principle of those I have criticised. It is neat and attractive in appearance, and designed for an economical and substantial-looking place. The arrangement of the rooms will commend itself, I think, to the architect and to the private party; it shows the kitchen department kept apart from the living rooms and entirely distinct in its situation and exclusiveness.

A Substitute for Wire Screens.

Every house-wife and servant fully understands by practical experience, the desirableness of a means by which kitchens, dining and other rooms may be ventilated, particularly during the summer months and warm days of the year, without being "tormented" by the presence of flies, mosquitoes, etc. This has usually been accomplished by means of wire screens on frames, or at the heads of the upper sash. A very simple and seemingly practical device, which does away with the metallic wire cloth, may be seen at W. Little's place of business, No. 128 Geary Street.

They can be applied to any window at small cost, and should command the special attention of families residing in districts where the heat of summer becomes oppressive, and to all who desire freedom from the presence of those winged intruders who never fail to swarm the apartments appointed for cooking and eating purposes.

The New Odd Fellows' Hall.

At the southwest corner of Market and 7th Streets, work has been commenced upon the foundations of a structure, the erection of which is destined to have a marked effect upon the values of surrounding property.

It has been a mooted question in regard to the building under consideration, upon the advisability of erecting an edifice of such magnitude, so far from the present location of the Order which it represents. Careful study has been given to the subject, and, wisely we think, the decision has been rendered in favor of the location adopted.

Property in the immediate neighborhood is mostly owned by men capable of making substantial improvements, and now that work has been commenced in earnest, it may be expected that, in the near future, other improvements will be commenced, and that the vicinity of the City Hall will shortly become a prosperous business center.

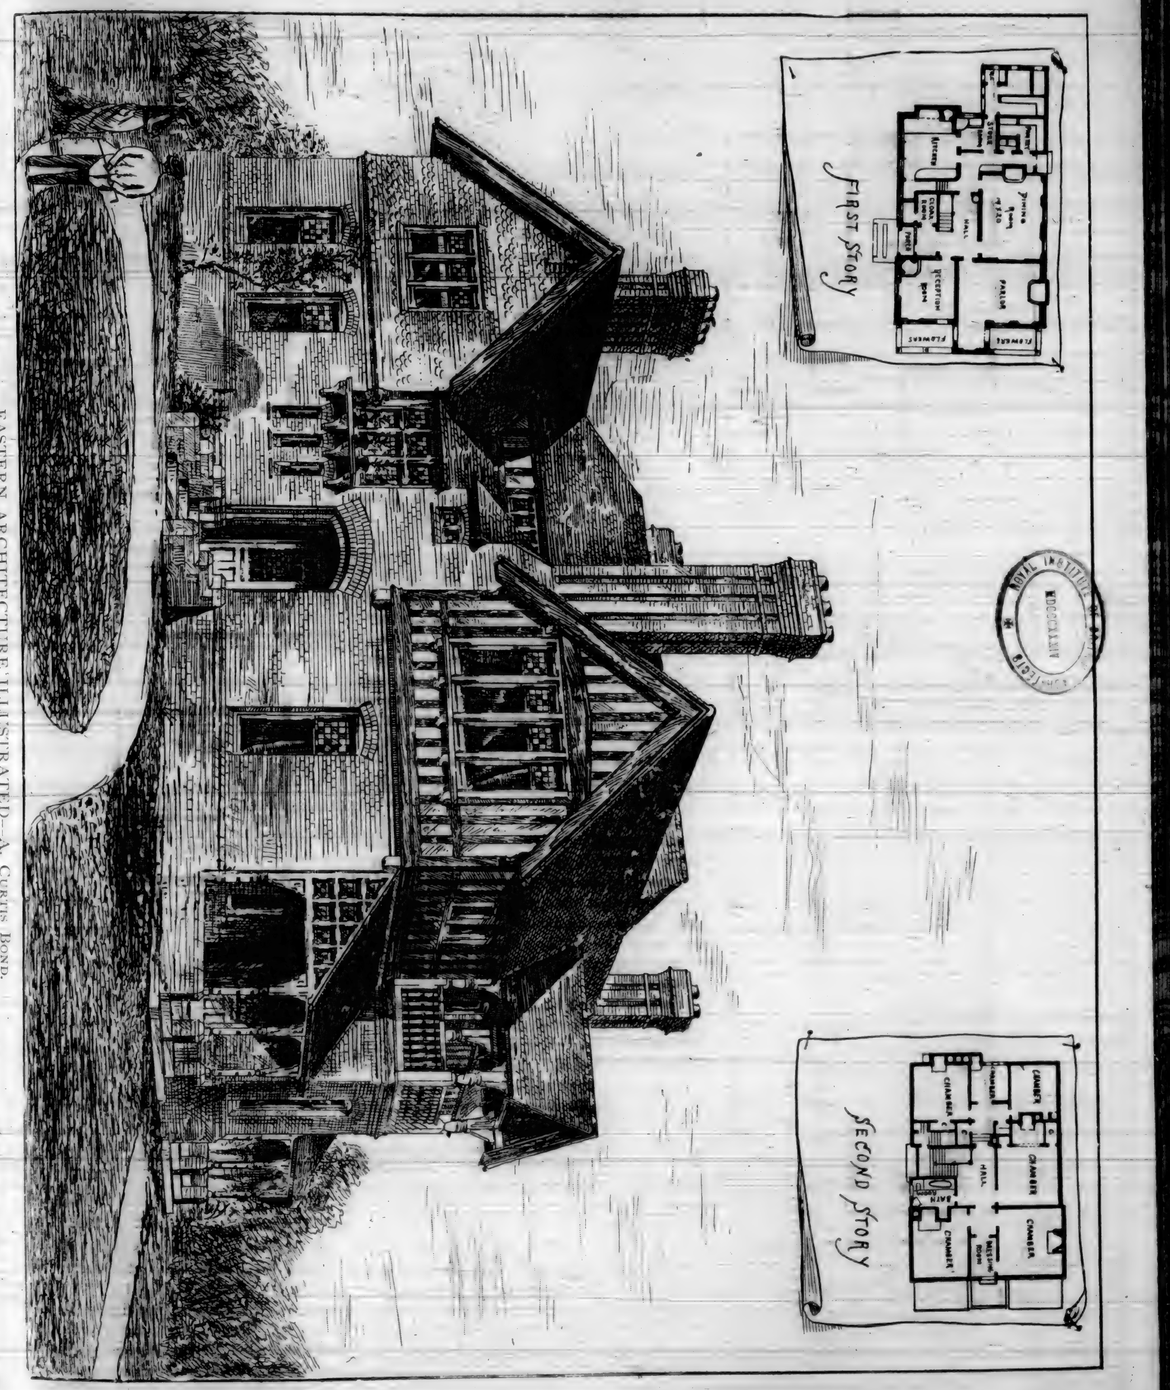
We hope to see property owners adopt designs in keeping with the character of the new I. O. O. F. building, and that contemplated by Murphy, Grant & Co., a short distance below the above site.

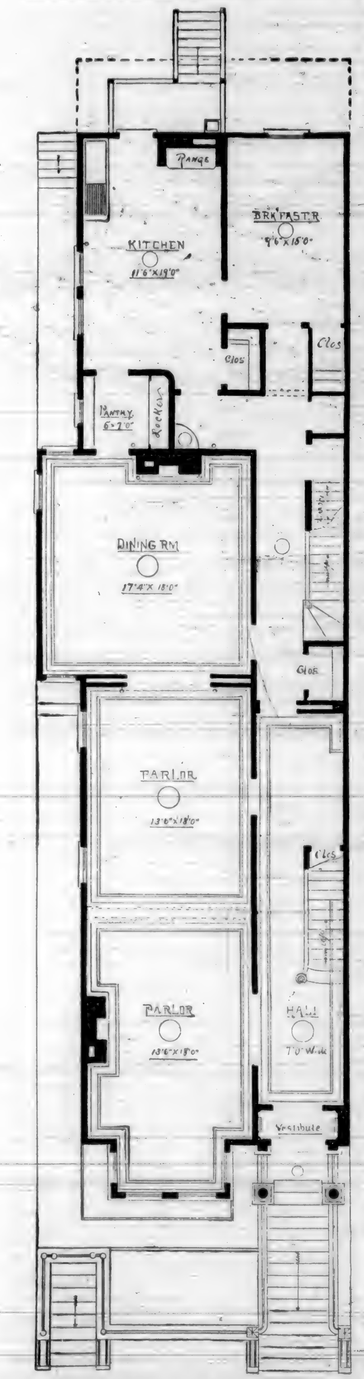
We hope to be able in the future to present full illustrations of the building. The Architects are Messrs. Wright & Sanders. The various contracts were awarded as follows:—

Brick work,	J. G. Liebert,
Carpenter,	Ed. Farrell,
Cast Iron,	R. Llewellyn,
Wrought Iron,	Phœnix Iron Works,
Roofing,	Cronin & Dunbar,
Plumbing,	Geo. Milne,
Plastering,	A. C. Corbett,
Painting,	E. M. Gallagher,
Granite,	Geo. Griffith,
Cement,	Davis & Cowell.

The estimated cost of the structure complete will be in the neighborhood of $300,000.

Steel Square and Its Uses, $1.00.





FIRST FLOOR PLAN OF $10,000 RESIDENCE.

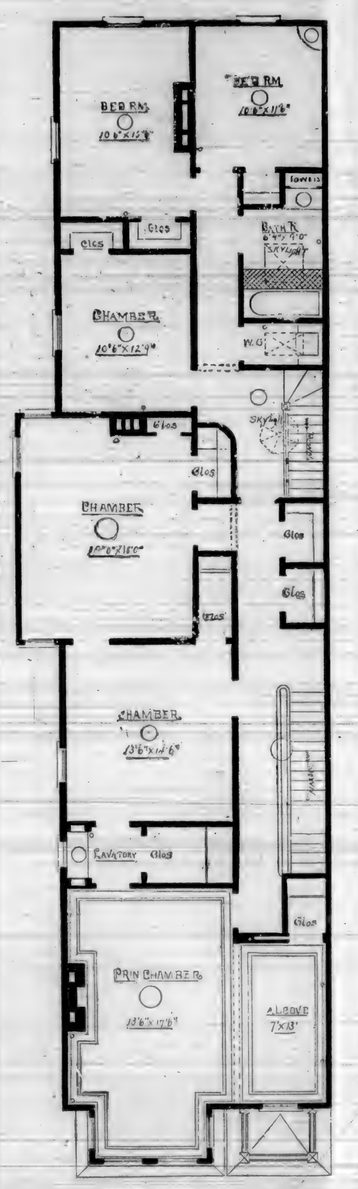
Custom Versus Specifications.

THERE can be nothing more provoking to a competent and upright architect, than, upon visiting buildings and works intrusted to him, to find portions of the work done in direct violation of the requirements of his specifications, and when attention is directed to the error, to be answered, "It is customary to do it so," "It is according to custom," etc. We have often regretted that we did not possess the muscle of a champion slogger, so that we might be able to thump consistency into such men, or throw them out of or clear over the building. It is nothing less than a deliberate insult to an architect to set aside the papers prepared by him, papers which, if the work of a competent man, are the result of careful thought and deliberation, expressing exactly what is wanted in kind and quality, and the mixture of impertinence and disrespect which will embolden parties to such a course is next to unbearable.

Who, we ask, is the leader in architectural fashions in house building? Who is the recognized man who issues this fiat of custom, and bids all to yield to his notions as to how this or that shall be? From whence comes "custom," "customary," "usual way," etc.? We denounce in emphatic terms all such absurdities, either upon the part of contractors, mill men, material men, or others, as far as intelligent architects, who understand and express in their specifications what they want—are concerned. It may serve a purpose among that class of architectural frauds, in San Francisco, who know nothing rightly about building houses; but it is an imposition upon decent men in the profession, to subject them to the necessity of even repudiating things done "according to custom," not in conformity with specifications. We know that there are architectural dudes, dunces, and shysters practicing the profession on this coast, and that they may be played with by any shrewd mechanic or contractor; but that fact does not justify attempts in the same direction upon men worthy the name of architects.

Personally, and for a majority of the gentlemen in the profession, we say to all parties performing contracts under our superintendence, we acknowledge no right in any one to change one iota from the requirements of our plans and specifications, and those who chance the substitution of "custom" for the plain language of plans and specifications, do so at the risk of rejection of the substitution, and the strict enforcements of the written requirements of the documents.

DID it ever occur to you how useful your thumb is? If it never has, supposing you tie it up a little while and see how helpless your fingers will be alone. We often say when anybody is particularly clumsy, that his fingers are all thumbs. This is simply slander on the hardest-worked and most useful of our five fingers.



SECOND FLOOR PLAN OF $10,000 RESIDENCE.

THE influence of Japan is beginning to be felt very considerably in architecture. Some things in Japanese architecture we shall, of course, probably never introduce—the heavy roof, for instance—but for verandas of country houses, for screens and for interior decorations, Japanese art and architecture is rapidly coming into use.

Unintelligent Estimating.

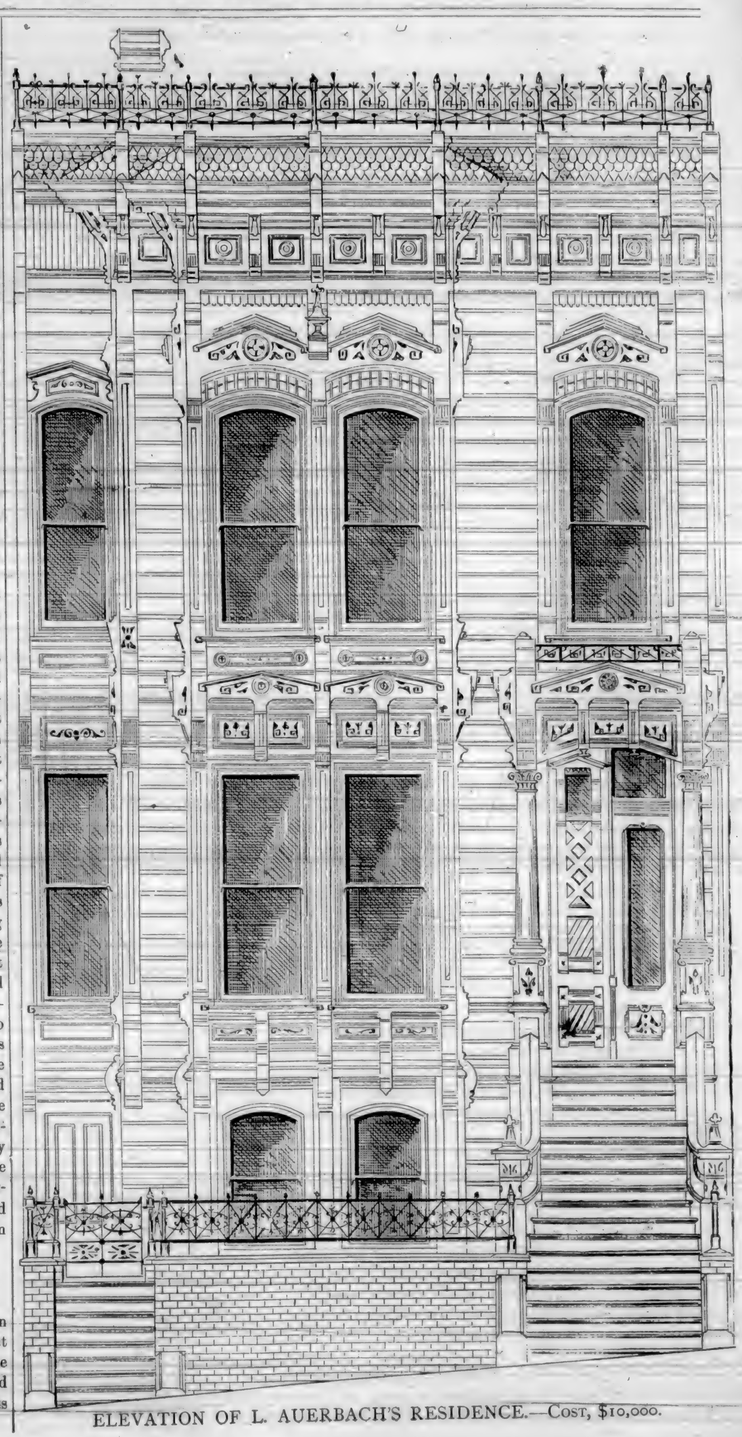
THE many absurd errors made manifest by the unreasonable difference, more generally prevailing in connection with estimates submitted for the erection of buildings, and the execution of mechanical works generally, is greatly to be regretted, for the reason that it lessens the confidence of owners in the competency and qualifications of contractors to intelligently determine the value of buildings or work offered for estimates.

It is not to be expected that each man should arrive at precisely the same conclusion as to costs, for the balances are not equal in all minds, and reasonable differences are legitimate. But when the discrepancies run from ten, twenty, fifty, and sometimes one hundred per cent or more, the fact becomes plain that absolute incompetency, unpardonable carelessness, excessive avarice, or an unintelligent understanding of what is contemplated, has controlled some of the parties figuring; and it is altogether proper for those offering work for estimates, to form adverse opinions as to the qualifications of contractors, when results as indicated are submitted for their consideration.

Nor is it always possible for architects to disabuse the minds of clients, that some of those who have estimated have not contemplated unfair and excessive advantages, and sought to secure more than legitimate gains and profits upon the operation proposed, which, followed to a logical conclusion, suggests, if it does not fully prove, that there are men even among "honest mechanics," who would not scruple to obtain other people's money without fair compensation—all of which tends to injure the reputation of those who manipulate figures in estimating, and devote their lives and energies as "master mechanics." All of these irregularities grow out of a lack of proper education and understanding of things generally, and a demoralized sentiment among contractors, who, as a class, figure and operate as each may deem best, using good and honest intent and correct judgment, or well-studied devices and unscrupulous means to secure—and in the management of work falling into their hands, as the case may be. All of this places at a disadvantage, if it does not make cheats and tricksters of good men, who would prefer fair and upright dealings, but are driven by surrounding circumstances and conditions to accept and practice the methods by which unscrupulous men make money, or be satisfied with the pittances which too generally follow in the path of those who stand upon the higher ground of strict integrity in all their transactions.

Garland's Trap.

PERHAPS the best recommendation that can be given to this Trap is to mention the fact that all the traps throughout the Lick House were removed to give place to the Garland Trap. This action speaks volumes for its merits.



ELEVATION OF L. AUERBACH'S RESIDENCE.—COST, $10,000.

The Competitive Pioneer Building Plans.

IN response to the invitation of the Building Committee, ten sets of plans, representing ten architectural firms, or combination of firms, have been submitted and placed on exhibition in the rooms of the society.

We do not propose at the present time to express an opinion as to the merits of the three or four better conceptions, but we do propose to say that the exhibit as a whole is not as creditable to the architectural talent of San Francisco as we should like to have seen, either in design or mechanical execution. With the more meritorious removed, the showing is poor, not coming within the limits of being worthy of serious attention.

The general result is in exact accord with the views expressed in this Journal in relation to the competition; and we are not, but should have been greatly suprised, had there been under the circumstances, and under the conditions proposed by the committee, a single set of plans and specifications submitted so *conspicuously meritorious*, as a whole, as to secure general and specific acknowledgment of superiority. As it is, there is great diversity of opinion upon the merits of the three or four sets of plans named as likely to receive favorable consideration, the others on exhibition being considered as "from poor to middling," and so on down to productions which should cause the blush of shame to mantle the cheeks of their authors, and would have that effect if all modesty and self-respect was not stultified by a superabundance of architectural libertinism or presumption.

The actual cash cost of the ten plans on exhibition will average not less than $350 each, or a total of $3 500. The greatest return possible under the conditions will be $950; so that the committee will ever hereafter enjoy the reflection that, by their management of the matter, seven silly men are out of pocket about—and perhaps more than $2,550. We do not pretend to say that the committee intentionally and designedly caused this result, but, whether of design or unintelligent management, the result is not changed, and seven men are none the less losers by the transaction, while the eighth and ninth, or those receiving the second and third prizes, will also be losers in the amount of $300, which added, will increase the total cash loss to nine men to $2,850.

Besides this, as has been stated in former issues, it is possible, and it sometimes so happens, that the plans receiving the first premium are second or third in actual merit, and, not unfrequently, the third *man* more than the merits of the third best plans, receives first premium. This course is excused upon the grounds of greater qualifications in the person of the third party as superintending architect. But that fact does not purify the act which draws men into competition upon the supposition and assurance that results will be determined solely upon the ground of merit in the plans presented, to the exclusion of all personal preferences and considerations. If plans are invited from parties without discrimination, then discrimination should not be admitted in determining issues as to plans, and when this is departed from, injustice intervenes.

We have no reasons to suppose that there is the slightest probability of such a course of action in the present case, but the possibility nevertheless exists.

Desirable Business Localities.

THE future of property on the line of Market and California Streets, and within the triangle formed by the streets named, is established beyond all peradventure. But the frontage on these and the intervening streets being far short of sufficient to supply the demands for choice business building sites, many who were compelled, or from choice desired to erect brick structures sufficient to meet the requirements of increased and increasing business, have been forced to seek out other streets and localities to find suitable purchasable property. Consequently the side streets, particularly those running southeasterly from Market Street, and lying northeasterly from First Street, and between Market and Mission Streets, have been the first to find favor with purchasers; and a number of substantial brick edifices have been erected on lots heretofore encumbered by old, worn-out frame, or dilapitated brick constructions; and it is a mere matter of time when the mills, shops, factories, and shanties of various character, at present occupying lots within the limits mentioned, will give place to permanent business structures.

FIRST STREET PROPERTY,

Between Market and Mission, which for so many years has remained at a stand-still, is now attracting attention; and with the removal of Union Foundry, which is likely to occur at an early day, there will be a general clearing away of the many old, worn rookeries, to make room for fine business buildings.

North from Market Street, judging from very suggestive indications, property on the line of

DAVIS STREET,

from Market to at least Washington Street, is among the most inviting, off from the prime avenues. The block from Market to California is built up solid with substantial buildings except one corner, which is in good hands and will in due time be changed from present one-story building, to one of several stories. The corners of California and Davis Street, are well improved, and also the southeast corner of Sacramento Street, the latter by Wangenheim & Co.'s four-story brick edifice. And preparations are now in progress to clear away old, and construct new buildings within the block last named. The property forming and running north from the northeast corner of Sacramento and Davis Streets, we are informed, is settled on for early improvement; and when what is now contemplated for Davis Street in the way of permanent buildings shall occur, which will be at an early period, the advance in present value of property on that thoroughfare will be vastly increased.

The experience of those seeking investment in business property—those who have declined to purchase at rates possible at certain periods, preferring to wait for a decline, have found prices at the end of one or two years waiting, largely advanced. So that it is safe to advise those seeking investments in the class of property referred to, not to procrastinate too long, as delays are dangerous, and time, as far as real estate in the business portion of the city is concerned, is more likely to advance than recede in prices during the next five years, at least.

Utilizing Old Files.

WORN-OUT files appear to be one of the few discarded articles in a machine shop for which no extensive use can be found. And yet files are made of the best cast steel and are in handy form for many purposes. The principal difficulty in the way of their economic utilization is that it costs more to remove the tooth marks and their consequences than the value of the resultant steel. It is quite futile to attempt the reforging of an old file so long as the chisel marks are left in; the steel will be "rotten." And it is not usually enough to barely remove the chisel cuts from sight, for the effect of the chisel cuts and hammer blows extends below their apparent bottom. It is evident, however, that there is a core of clean, useful steel below this corrugated surface.

In a shop recently visited a very inexpensive process of removing the tooth marks of old files was noticed. A belt led from a small pulley on the axle of the grindstone to a horizontal shaft near the floor, and as far forward as the front of the grindstone. This shaft carried a bevel gear that engaged with another on an upright shaft at the side of the grindstone frame, on the top of which was a slotted disk carrying a stud that could be secured at any point in the slot, thus forming a crank of differing radius. To this stud was attached a pitman that gave a reciprocating motion to a slide that received a file, held at point and tang, the slide or its box being kept against the face of the stone by a spring. Thus the file was passed back and forth against the face of the stone, not only gradually losing its tooth corrugations, but keeping the stone razed to an even face. No attention was necessary, but an occasional turning of the file from one side or edge to another, and its removal and replacement by another file.

These smooth file blanks were then useful for a variety of purposes—scrapers for finishing, cutters for boring bars, flat reamers, etc.—*Scientific American.*

Album of Mantels.

A PERFECTLY new work containing SIXTY large plates of designs for every description of MANTELS in wood, stone, slate and brick.

In our last issue the price was incorrectly given at $5.00. It should have been **$8.00**. We will forward a copy to any address upon receipt of EIGHT DOLLARS.

B. E. Henriksen.

THIS gentleman has the honor of being the pioneer native-born architect, claiming, as he does, April 19, 1851, in this city, as the date and place of his nativity.

In June, 1866, he entered the office of P. Huerne as an apprentice. Passing through the grades of student, draughtsman, and associate, in 1875 we find him connected with that gentleman as partner. He remained in that capacity until September, 1881.

During the latter period, Mr. Henriksen spent much labor and study on the perfection of safety clutches for elevators. In January, 1880, he obtained a patent for a Pneumatic Safety Clutch. In July of the same year, he conceived a totally different principle from any that had up to that time been applied, and one that has made his name favorably known on this coast wherever elevators are used. We allude to the AUTOMATIC SAFETY CLUTCH This has been extensively used in this city, and is recommended on account of its simplicity, and its non-liability to get out of order.

In 1882 Mr. Henriksen visited many of the Eastern States, introducing his Clutch at the principal cities. Returning to this city, he resumed the practice of his profession in August, 1883.

Mr. Henriksen has participated in many of the architectural competitions that have taken place in this city. In 1873 he received second premium for the hall of the Scandinavian Association; in 1875, first premium for the Red Men's Hall; in 1877, second premium for the Girl's High School.

Mr. Henriksen is an earnest worker in San Francisco Chapter of Architects, being one of the Trustees of that society. He attends to "committee work" with commendable zeal. He also is an active member of many of the fraternal associations, in several of which he has held the highest offices.

B. E. HENRIKSEN.

TO CLEAR OUT COAL SMOKE.—If troubled with the smoke from soft coal so that you cannot lay your clothes on the grass to bleach, you can improve their looks in this way: After rubbing them, pour absolutely boiling water over them, and let them lie in this water all night. Next morning scald and rinse as usual. This does a great deal toward clearing out the yellowish color they would otherwise certainly have.

Deafening Floors.

THE transmission of sound between rooms in two contiguous stories of a building, oftentimes becomes very annoying to those occupying the lower story. As the power of a solid body to transmit sound is in proportion to its density, it is a matter of easy correction, in most cases similar to the above, when undertaken at the time of construction.

The old and primitive method of depositing a quantity of wet mortar on rough boards between the floor beams, etc., has, in many cases, been a cure quite as bad as the disease. The transmission of sound was lessened in a degree, but the dampness of the mortar was absorbed by the contiguous lumber, and, sooner or later, produced decay—dry rot. The use of sawdust is only a palliation, for it is likely, after a time, to absorb dampness, and be reluctant to part with it. It also furnishes rats and mice a splendid material for nesting. Wool felt is an enduring, elastic material, and when laid in strips equal to the width of and on top of the floor beams, the flooring, when laid, is uniformly separated from the direct sound conductors to the story below. Use the felt in thicknesses of a quarter to a third of an inch. The method of interposing a layer of mineral wool between the under and upper floors, is a good one. On top of the first floor, narrow strips, 2x2 inches, are placed 16 to 24 inches apart, and the intermediate spaces filled with mineral wool, placed in loosely—not packed, and the top layer of flooring nailed in position. By this method, a warm, muffled, and partially fireproof floor is secured without the use of any materials to produce dry rot, or become the nesting-place for vermin.

IT has taken years of improvement to make headway against the strange notion that improved machinery and mechanical processes work against the workingman. It has been the cry at every new step in advance that it would be the death-blow to some industry formerly carried on by hand. The locomotive was to do away with teaming. The sewing-machine was to be a foul crime against the welfare of the seamstress. The reaper and mower were to interfere with the rights of the sturdy swathe-cutter of the farms. In short, every such advance has been met by just such objections. Yet there is less poverty, less squalor, less ignorance, and less idleness among the laboring classes in our age, which is the age of invention, and in our land, the land of inventive genius, than in any other age or land the world has ever known.

DEAD-FINISH.—This term, says an exchange, is applied to the finish produced by the reduction of any of the rubbing varnishes with powdered pumice-stone and raw linseed oil, the surface thus produced being left in the semi-lustrous state by omitting the polishing process. It is now more used than any other for body work, shellac varnish being generally employed, because of its adaptation to the requirements of fine cabinet-work, and properties of quick and hard drying. Copal anime, and amber varnishes are also used, but are slower drying. Veneered panels are usually "flowed" or "polished" when the body work is dead-finished. The number of coats required depends somewhat upon the quality of the filler, but usually three coats, and sometimes less, are amply sufficient.—*Carpentry and Building.*

AS REGARDS brick foundations for machinery, the late Mr. Trautwine, who experimented a good deal with building materials, said that a rather soft brick will crush under a weight of about thirty or forty tons per square foot, whilst a first-rate machine-pressed brick will require from three to four hundred tons per square foot.—*The Builders and Manufacturers' Journal.*

The Competitive Pioneer Building Plans.

In response to the invitation of the Building Committee, ten sets of plans, representing ten architectural firms, or combination of firms, have been submitted and placed on exhibition in the rooms of the society.

We do not propose at the present time to express an opinion as to the merits of the three or four better conceptions, but we do propose to say that the exhibit as a whole is not as creditable to the architectural talent of San Francisco as we should like to have seen, either in design or mechanical execution. With the more meritorious removed, the showing is poor, not coming within the limits of being worthy of serious attention.

The general result is in exact accord with the views expressed in this Journal in relation to the competition; and we are not, but should have been greatly suprised, had there been under the circumstances, and under the conditions proposed by the committee, a single set of plans and specifications submitted so *conspicuously meritorious*, as a whole, as to secure general and specific acknowledgment of superiority. As it is, there is great diversity of opinion upon the merits of the three or four sets of plans named as likely to receive favorable consideration, the others on exhibition being considered as "from poor to middling," and so on down to productions which should cause the blush of shame to mantle the cheeks of their authors, and would have that effect if all modesty and self-respect was not stultified by a superabundance of architectural libertinism or presumption.

The actual cash cost of the ten plans on exhibition will average not less than $350 each, or a total of $3.500. The greatest return possible under the conditions will be $950; so that the committee will ever hereafter enjoy the reflection that, by their management of the matter, seven silly men are out of pocket about—and perhaps more than $2.550. We do not pretend to say that the committee intentionally and designedly caused this result, but, whether of design or unintelligent management, the result is not changed, and seven men are none the less losers by the transaction, while the eighth and ninth, or those receiving the second and third prizes, will also be losers in the amount of $300, which added, will increase the total cash loss to nine men to $2.850.

Besides this, as has been stated in former issues, it is possible, and it sometimes so happens, that the plans receiving the first premium are second or third in actual merit, and, not unfrequently, the third *man* more than the merits of the third best plans, receives first premium. This course is excused upon the grounds of greater qualifications in the person of the third party as superintending architect. But that fact does not purify the act which draws men into competition upon the supposition and assurance that results will be determined solely upon the ground of merit in the plans presented, to the exclusion of all personal preferences and considerations. If plans are invited from parties without discrimination, then discrimination should not be admitted in determining issues as to plans, and when this is departed from, injustice intervenes.

We have no reasons to suppose that there is the slightest probability of such a course of action in the present case, but the possibility nevertheless exists.

Desirable Business Localities.

The future of property on the line of Market and California Streets, and within the triangle formed by the streets named, is established beyond all peradventure. But the frontage on these and the intervening streets being far short of sufficient to supply the demands for choice business building sites, many who were compelled, or from choice desired to erect brick structures sufficient to meet the requirements of increased and increasing business, have been forced to seek out other streets and localities to find suitable purchasable property. Consequently the side streets, particularly those running southeasterly from Market Street, and lying northeasterly from First Street, and between Market and Mission Streets, have been the first to find favor with purchasers; and a number of substantial brick edifices have been erected on lots heretofore encumbered by old, worn-out frame, or dilapitated brick constructions; and it is a mere matter of time when the mills, shops, factories, and shanties of various character, at present occupying lots within the limits mentioned, will give place to permanent business structures.

FIRST STREET PROPERTY,

Between Market and Mission, which for so many years has remained at a stand-still, is now attracting attention; and with the removal of Union Foundry, which is likely to occur at an early day, there will be a general clearing away of the many old, worn rookeries, to make room for fine business buildings.

North from Market Street, judging from very suggestive indications, property on the line of

DAVIS STREET,

from Market to at least Washington Street, is among the most inviting, off from the prime avenues. The block from Market to California is built up solid with substantial buildings, except one corner, which is in good hands and will in due time be changed from present one-story building, to one of several stories. The corners of California and Davis Street, are well improved, and also the southeast corner of Sacramento Street, the latter by Wangenheim & Co.'s four-story brick edifice. And preparations are now in progress to clear away old, and construct new buildings within the block last named. The property forming and running north from the northeast corner of Sacramento and Davis Streets, we are informed, is settled on for early improvement; and when what is now contemplated for Davis Street in the way of permanent buildings shall occur, which will be at an early period, the advance in present value of property on that thoroughfare will be vastly increased.

The experience of those seeking investment in business property—those who have declined to purchase at rates possible at certain periods, preferring to wait for a decline, have found prices at the end of one or two years waiting, largely advanced. So that it is safe to advise those seeking investments in the class of property referred to, not to procrastinate too long, as delays are dangerous, and time, as far as real estate in the business portion of the city is concerned, is more likely to advance than recede in prices during the next five years, at least.

Utilizing Old Files.

Worn-out files appear to be one of the few discarded articles in a machine shop for which no extensive use can be found. And yet files are made of the best cast steel and are in handy form for many purposes. The principal difficulty in the way of their economic utilization is that it costs more to remove the tooth marks and their consequences than the value of the resultant steel. It is quite futile to attempt the reforging of an old file so long as the chisel marks are left in; the steel will be "rotten." And it is not usually enough to barely remove the chisel cuts from sight, for the effect of the chisel cuts and hammer blows extends below their apparent bottom. It is evident, however, that there is a core of clean, useful steel below this corrugated surface.

In a shop recently visited a very inexpensive process of removing the tooth marks of old files was noticed. A belt led from a small pulley on the axle of the grindstone to a horizontal shaft near the floor, and as far forward as the front of the grindstone. This shaft carried a bevel gear that engaged with another on an upright shaft at the side of the grindstone frame, on the top of which was a slotted disk carrying a stud that could be secured at any point in the slot, thus forming a crank of differing radius. To this stud was attached a pitman that gave a reciprocating motion to a slide that received a file, held at point and tang, the slide or its box being kept against the face of the stone by a spring. Thus the file was passed back and forth against the face of the stone, not only gradually losing its tooth corrugations, but keeping the stone razed to an even face. No attention was necessary, but an occasional turning of the file from one side or edge to another, and its removal and replacement by another file.

These smooth file blanks were then useful for a variety of purposes—scrapers for finishing, cutters for boring bars, flat reamers, etc.—*Scientific American.*

Album of Mantels.

A perfectly new work containing sixty large plates of designs for every description of mantels in wood, stone, slate and brick.

In our last issue the price was incorrectly given at $5.00. It should have been **$8.00**. We will forward a copy to any address upon receipt of eight dollars.

B. E. Henriksen.

This gentleman has the honor of being the pioneer native-born architect, claiming, as he does, April 19, 1851, in this city, as the date and place of his nativity.

In June, 1866, he entered the office of P. Huerne as an apprentice. Passing through the grades of student, draughtsman, and associate, in 1875 we find him connected with that gentleman as partner. He remained in that capacity until September, 1881.

During the latter period, Mr. Henriksen spent much labor and study on the perfection of safety clutches for elevators. In January, 1880, he obtained a patent for a Pneumatic Safety Clutch. In July of the same year, he conceived a totally different principle from any that had up to that time been applied, and one that has made his name favorably known on this coast wherever elevators are used. We allude to the Automatic Safety Clutch This has been extensively used in this city, and is recommended on account of its simplicity, and its non-liability to get out of order.

In 1882 Mr. Henriksen visited many of the Eastern States, introducing his Clutch at the principal cities. Returning to this city, he resumed the practice of his profession in August, 1883.

Mr. Henriksen has participated in many of the architectural competitions that have taken place in this city. In 1873 he received second premium for the hall of the Scandinavian Association; in 1875, first premium for the Red Men's Hall; in 1877, secured premium for the Girl's High School.

Mr. Henriksen is an earnest worker in San Francisco Chapter of Architects, being one of the Trustees of that society. He attends to "committee work" with commendable zeal. He also is an active member of many of the fraternal associations, in several of which he has held the highest offices.

B. E. Henriksen.

To Clear out Coal Smoke.—If troubled with the smoke from soft coal so that you cannot lay your clothes on the grass to bleach, you can improve their looks in this way: After rubbing them, pour absolutely boiling water over them, and let them lie in this water all night. Next morning scald and rinse as usual. This does a great deal toward clearing out the yellowish color they would otherwise certainly have.

Deafening Floors.

The transmission of sound between rooms in two contiguous stories of a building, oftentimes becomes very annoying to those occupying the lower story. As the power of a solid body to transmit sound is in proportion to its density, it is a matter of easy correction, in most cases similar to the above, when undertaken at the time of construction.

The old and primitive method of depositing a quantity of wet mortar on rough boards between the floor beams, etc., has, in many cases, been a cure quite as bad as the disease. The transmission of sound was lessened in a degree, but the dampness of the mortar was absorbed by the contiguous lumber, and, sooner or later, produced decay—dry rot. The use of sawdust is only a palliation, for it is likely, after a time, to absorb dampness, and be reluctant to part with it. It also furnishes rats and mice a splendid material for nesting. Wool felt is an enduring, elastic material, and when laid in strips equal to the width of and on top of the floor beams, the flooring, when laid, is uniformly separated from the direct sound conductors to the story below. Use the felt in thicknesses of a quarter to a third of an inch. The method of interposing a layer of mineral wool between the under and upper floors, is a good one. On top of the first floor, narrow strips, 2x2 inches, are placed 16 to 24 inches apart, and the intermediate spaces filled with mineral wool, placed in loosely—not packed, and the top layer of flooring nailed in position. By this method, a warm, muffled, and partially fireproof floor is secured without the use of any materials to produce dry rot, or become the nesting-place for vermin.

It has taken years of improvement to make headway against the strange notion that improved machinery and mechanical processes work against the workingman. It has been the cry at every new step in advance that it would be the death-blow to some industry formerly carried on by hand. The locomotive was to do away with teaming. The sewing-machine was to be a foul crime against the welfare of the seamstress. The reaper and mower were to interfere with the rights of the sturdy swathe-cutter of the farms. In short, every such advance has been met by just such objections. Yet there is less poverty, less squalor, less ignorance, and less idleness among the laboring classes in our age, which is the age of invention, and in our land, the land of inventive genius, than in any other age or land the world has ever known.

Dead-Finish.—This term, says an exchange, is applied to the finish produced by the reduction of any of the rubbing varnishes with powdered pumice-stone and raw linseed oil, the surface thus produced being left in the semi-lustrous state by omitting the polishing process. It is now more used than any other for body work, shellac varnish being generally employed, because of its adaptation to the requirements of fine cabinet-work, and properties of quick and hard drying. Copal anime, and amber varnishes are also used, but are slower drying. Veneered panels are usually "flowed" or "polished" when the body work is dead-finished. The number of coats required depends somewhat upon the quality of the filler, but usually three coats, and sometimes less, are amply sufficient.—*Carpentry and Building.*

As regards brick foundations for machinery, the late Mr. Trautwine, who experimented a good deal with building materials, said that a rather soft brick will crush under a weight of about thirty or forty tons per square foot, whilst a first-rate machine-pressed brick will require from three to four hundred tons per square foot.—*The Builders and Manufacturers' Journal.*

Peculiar Wood Working.

THE auger is intended primarily for making holes in wood, yet the only cutting or boring portion is the chisel lip on its lower end: and if the implement could be kept at its work and guided in its course, the gimlet screw at its point and the spiral above its cutting portion might be dispensed with, as the screw merely pulls the cutter into the work and the spiral guides the auger and elevates the chips. So the auger, deprived of these portions, becomes a rotary cutter by which straight or curved recesses of a definite width may be cut. Mortises for tenons are made with such an implement, and it is used also for many other similar purposes.

An adaptation of the circular saw is more peculiar than this. It is the cutting of a wide kerf with a thin saw; thus a saw of one-fourth of an inch thickness, or "set," cuts a score, or slot, of three-quarters of an inch or more. In appearance the saw is anything but mechanical, and at first thought the method is "sloppy" and foolish. But the result of the work is good. The effect is produced by placing a circular saw on an arbor somewhat smaller than the hole through the saw, and canting the saw to an angle by means of convex faced glands or flanges. When rotated the saw's periphery has a "wabbling" motion, so that twice in its revolution the saw cuts out of its true kerf on either side. It will be seen that if the quarter-inch saw is set one-quarter of an inch out of truth on its side, it will cut one-quarter of an inch on each side, making, with the primary thickness of the saw itself, a cutting width of three-quarters of an inch. This apparently crude method produces very satisfactory results. It might be supposed that such eccentricity of movement from side to side would leave very coarse score mark on each side of the cut, but the velocity of the saw's rotation compared with the feed insures perfectly clean work. The advantages of this method are that the power required to cut a wide kerf with a narrow saw by gradations is much less than to cut the full kerf at once with full wide cutters, and that while a saw can be of diameter large enough to cut through a wide or thick piece of lumber, there is a much lower limit to the economical and effective projection of chisel cutters from a head. One of the largest manufactories of agricultural and domestic machinery and implements in the country has used circular saws in this manner for years.

SCISSORS have become the subject of a new patent. We thought this was impossible. Some one has attached a third blade, to be used exclusively for ripping.

MILDEW may be removed by dipping the stained parts into butter-milk, and putting them into the sun.

MOTH-INFESTED articles should be saturated in naphtha or benzine. It injures nothing, and kills the destroyer.

Ventilated Bedclothes.

CONSIDERING that most of us pass one-third of our lives in bed, it is manifestly of considerable importance to see that the conditions under which we exist for eight hours out of every twenty-four are, as far as we can make them, healthy. It must be obvious that it cannot be conducive to health to accumulate the exhalations from our bodies, and adopt such measures as may insure our taking them again into our lungs. That which is thrown off, either in the breath or by prespiration, sensible or insensible, must clearly be excrementitious, and therefore ought to be allowed to pass away. We should not breathe air or vapor which is laden with the debris of the body, though that body be our own. Another point of moment is that we should not allow our strength to be weakened by excessive heat and action of the skin during a third of our time.

It is, therefore, with great pleasure we find that an attempt has been made to ventilate quilts. We do not quite understand the process which has just been patented, but it is said to consist in a system of perforations which are filled in with some substance that allows the vapor to escape. We are informed that the artifice, whatever it be, is entirely successful. Something of the sort is beyond doubt much needed. It is well to lie warm at night, so far as the more important parts of the body are concerned; but it is most undesirable to be too warm, and, above all, "stuffy," while we sleep.—*The Manufacturer and Builder.*

Bricks.

THE best method of developing the art of building in brick has occupied the attention of architects and engineers in Switzerland for some years, and with this view it has been determined to attempt to fix a certain standard size of brick, and a report was presented to the Swiss Society of Architects and Engineers, in which the dimensions recommended were 9.84 inches by 4.72 by 2.36 inches. As, however, these dimensions were not agreed to by all sections of the society, a special federal commission was appointed in December, 1882, to inquire into the subject. A report was presented to the General Assembly of Cantonal delegates at Berne by M. Favod. With regard to the question of price, of course, if the manufacturer sells his bricks by the thousand, without reference to size, the smaller they are the better for him. The contractor, too, is apt to prefer small bricks, because with them he uses more mortar, which costs him less; but, on the other hand, he requires more bricks per cubic yard (the number of bricks of different sizes in a cube meter of work are given), and there is more labor in setting them, so that what he gains in one way he loses in another.

In regard to the quantity of mortar, Dr. Boehme's experiments at Berlin in 1875 proved that no more mortar than was actually necessary to keep the course horizontal and effect the cohesion of the bricks (for which purpose joints of 0.4 inch thick are ample) should be used. as whether the mortar becomes more or less hard than the bricks, the result is in either case to reduce the strength of the work.

Experiments made with blocks of twenty sound bricks, one set of blocks cemented with various kinds of mortar and cement (the joints 0.4 inch thick), another set consisting of bricks laid dry, and surrounded with cement simply to keep them together, gave, as mean resistances to compression: For the first set, 1,618 lbs. per square inch to cause splitting, 1,934 lbs. for the destruction of the bricks; and for the second set, 2,202 lbs. per square inch to cause splitting, and 2,291 lbs. per square inch for destruction, showing that the dry bricks gave a mean resistance of one-third more than those set with mortar before splitting, and one-fifth more before destruction.

The author, therefore, concludes that to secure the greatest strength, thick bricks, with a minimum of mortar, should be used. The author suggests that the price of bricks per thousand should vary, according to the number required per cubic meter of work, so that the manufacturer may be paid according to the size of the bricks. Finally, he recommends that the standard brick should have the dimensions 9.84 inches by 4.72 inches by 2.56 inches.—*Cincinnati Building Review.*

Hints in Fret Sawing.

A PRACTICAL fret-sawyer gives the following useful hints to amateur workmen: In cutting a pattern of any kind make it a rule to leave the outside until the last, especially where there are any single leaves or flowers at the sides or corners. Never allow the saw to become very hot, or a breakage is pretty sure to be the result. Notice before commencing work whether there are any knots in the wood, and if so mark the spot with a pencil on your pattern, and work very cautiously when you come across it. Stop working directly you see your saw edging away from or into the pattern, and make a fresh start in another place. When you have finished sawing out your bracket or whatever it may be, remove your pattern by moistening it with a little cold water, and while the wood is still damp fasten it on to your table with small nails pushed into the corners of the pattern. When thoroughly dry the bracket must be well sandpapered, firstly with a coarse, then with fine, and thirdly with oiled fine sandpaper. Rub in plaster of Paris with oil, dry twenty-four hours, then polish or varnish.—*Art Amateur.*

WOODEN PAVEMENTS IN BERLIN.—It has been noted as a curious fact by some observant person, that while wooden pavements have proved such miserable failures in almost every American city, they have proved very successful in Berlin. There should be some reason for this, and our engineers should have sufficient curiosity to findout what the reason is.

The Pyramids of Teotihuacan.

BY E. J. MOLERA.

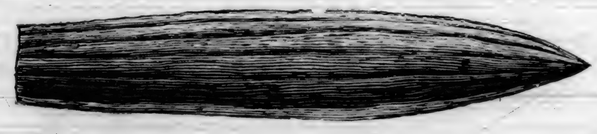
Two years ago I had the opportunity of visiting the famous pyramids of Teotihuacan. I had the good fortune of making the trip with Mr. Ziehl, a German Mexican, member of the Mexican Geographical Society, a fine Mexican philologist, one of the few who had visited the pyramids and knows a great deal about them, having formed part of the Mexican Commission sent to Teotihuacan to explore the monuments there.

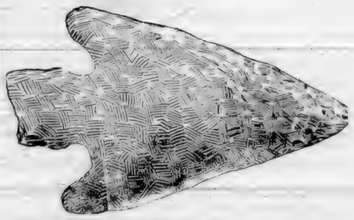
Early in the morning we started on the Vera Cruz train, which is there as our overland. On board we had a body of 200 soldiers to guard the train, a luxury the United States could not afford with her little army.

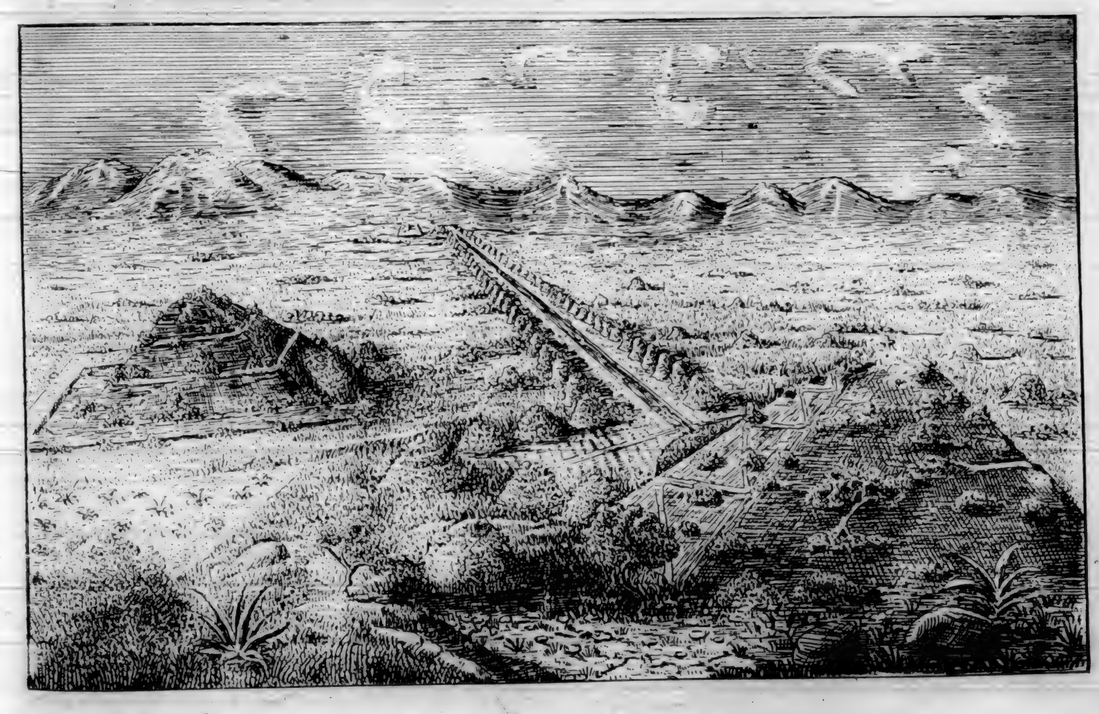
The sun was spreading his golden rays over the silvered tops of the Popocatepetl and Iztaccihuatl, flooding with light the beautiful and romantic valley of Mexico. Moving along with the train, the imagination cannot keep pace with the numerous recollections that history brings to the mind by the sight of the monuments spread before the eyes of the traveler.

We see, at our starting "Coapan," "Tlatelolco," and "Saint James Tecpan," where the heroic Cuauhtemoc, the last emperor of the Aztecs, was taken prisoner while endeavoring to run away with his family in a canoe. He is said to have told Cortez to kill him, as he could no further defend his country. Near that very spot are the ruins of the palace of the Aztec governor sent by the Mexican Crown to the city of Tlatelolco. A moment after we are at the Guadalupe Causeway, built by the Franciscan monks, at the head of which presided Fray Joan, of Torquemada, the Mexican Titus Livius. At the end of that causeway we find Guadalupe, where the treaty between the United States and Mexico was signed in 1848. There is the temple, where the Indian virgin is worshiped. A mast of a ship can be seen carried all the way from Vera Cruz by sailors who believed themselves to have been saved by that virgin from shipwreck. At our right we see Lake Texcoco, covered formerly with acalis, as to-day is Chalco, with chinampas, or floating gardens. Only a few minutes more and we pass Ehecatepec where the patriot Morelos was shot in 1815. After a little while we stop at the station of Teotihuacan to go by stage to the town of the same name. From that point we walk for a mile through a thicket of cactus, organs, perus, etc., and arrive at a deep gulch, which we cross, and find ourselves in a troglodytic field. Numerous openings show the entrances of subterranean caverns. I entered some of them, but did not find the end of many; they probably intercommunicate with one another, and go to great distances. Here begins the Indian sacred ground; at every step we find obsidian points, which are there still called by the Aztec name of *itztli*. A short walk places us before the great pyramids.

They are situated at twenty-eight miles from the Capital of Mexico, to the northeast,







and not the northwest, as Mendoza says. They are two in number, though lesser tumuli, or earth mounds, abound around and in the vicinity of them. Torquemada asserts that, in his time, there were no less than 2,000, which probably were only a part of the ones built originally.

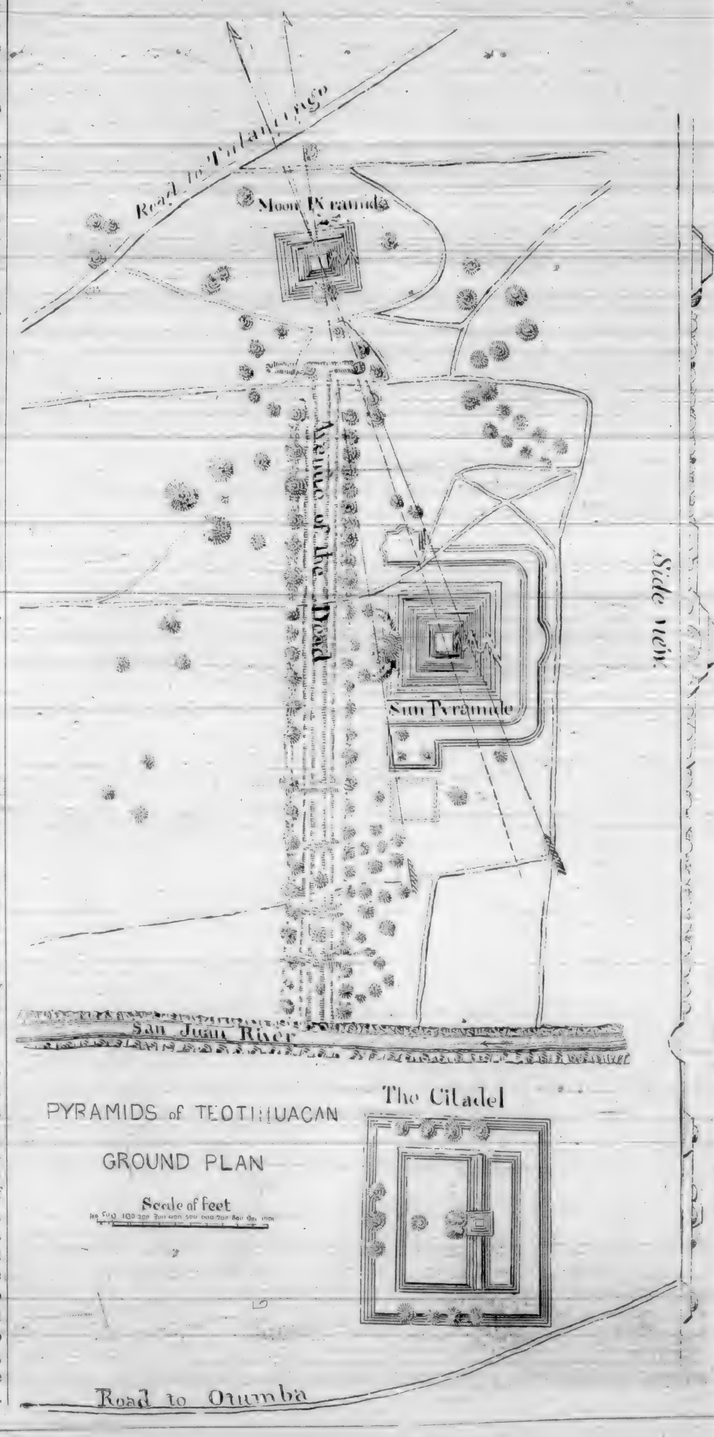
At the northern extremity heads the *Mezetli Itzacual*, or Pyramid of the Moon. The observer placed on its summit and looking southward sees close to its base a square about five hundred feet on each side, formed of tumuli, or mounds, which the Mexicans call *tlalles* or *cocillos*. Starting from that square, there is an avenue several miles long and about two hundred feet wide, with a line of earth mounds, or *tumuli*, on either side. These are very well defined for a distance of nearly a mile, where they cross the San Juan River. This avenue was called by the Mexicans *Micoatl*, or the "Avenue of the Dead." The earth mounds are elevated from the level of the avenue, and along it, on either side, run wide sidewalks, in the shape of steps. Midway between the Pyramid of the Moon and the San Juan River, or at a distance of 2,600 feet from the Pyramid of the Moon, stands *Tonatiuh Itzacual*, or Sun Pyramid. At the other side of the San Juan River, a large, walled square, called the Citadel, with a pyramid near its center, forms the third prominent structure of this remarkable group of prehistoric monuments.

The geographical positions of these monuments, as determined by the scientific commission of Pachuca, are as follows:—

Moon Pyramid, Lat., 19°, 41', 52.80"; Long., 6h., 35m., 18.32 sec., Greenwich time. Sun Pryamid, Lat., 19°, 41', 26.74"; Lon., 6h., 35m., 18.32 sec., Greenwich time. Citadel Pyramid, Lat., 19°, 40', 51.57"; Long., 6h., 35m., 18.96 sec., Greenwich time.

The sides of these pyramids do not follow the direction of the cardinal points, as stated by Brasseur de Bourbourg, and others, and as the Egyptian pyramids do. The Moon Pyramid follows just now the magnetic points, but that is only an accidental circumstance. The sides of the Pyramid of the Sun, as well as the Citadel, follow intermediate points of the compass.

There is, however, this remarkable circumstance in the situation of the pyramids, that the line joining the centers of both, follows within two degrees a true north and south line. The little decrepancy may be accounted for by the supposition that they were aligned by some star near the pole at the time of their construction, probably Alpha Draconis, but not Polaris, as, erroneously, Almaraz says. Taking in consideration that the pyramid builders nearly always placed the sides of the pyramids in parallel lines, I am inclined to think that the diagonals of the quadrilateral forming the bases of the pyramid, point to two prominent points in the Valley of Mexico, which can be determined as soon as accurate surveys of the pyramids and valley are made.



PYRAMID OF THE MOON.

This is the smaller of the two. The base is a rectangular quadrilateral, 511 feet long on the sides running east and west, and 426 those running north and south, the elevation from the base is 138 feet. The dimensions given by Clavijero, viz., 88 by 86 perches, or 1,492 by 1,319 feet, are three times too large. It covers a surface larger than the Superior, and nearly as great as the Great Pyramid of Egypt, or twice as large as our Union Square.

This pyramid, as well as that of the Sun, was formerly divided in four stages, or bodies, separated by a walk around three of its sides. One of these divisions is plainly visible yet, at a height of about seventy feet from the ground. The side without walks or steps is at the east, and there is at present the zigzag road to ascend them. But, according to Clavijero, there were formerly steps at the sides in the same fashion as those of the *teocalis* and the great Cu in the city of Mexico.

The manner of building these pyramids is by layers parallel to the sides, and not horizontally as we would build them; the material is a kind of McAdam composition. First is a layer of boulders and mud about thirty inches thick, the boulders being about ten inches on each side. On top of this there is another layer, six inches thick, of mud mortar, and finally a finishing coat of lime. These layers are repeated over again through the whole mass, as far as it has been uncovered. It is possible that when properly examined some variations may be found.

PYRAMID OF THE SUN.

This is the larger of the two, with a rectangular base 735 feet east and west, 761 feet north and south. Its height is 203 feet. It covers an area as large as the Cheops, or Splendid Pyramid, in Egypt, and larger than our largest square, Alamo, or Lafayette Park. Around this pyramid there is a very large wall, 131 feet wide and 20 feet high. This wall is discontinued at the west side. The faces are not vertical, but inclined, or in talus.

THE CITADEL.

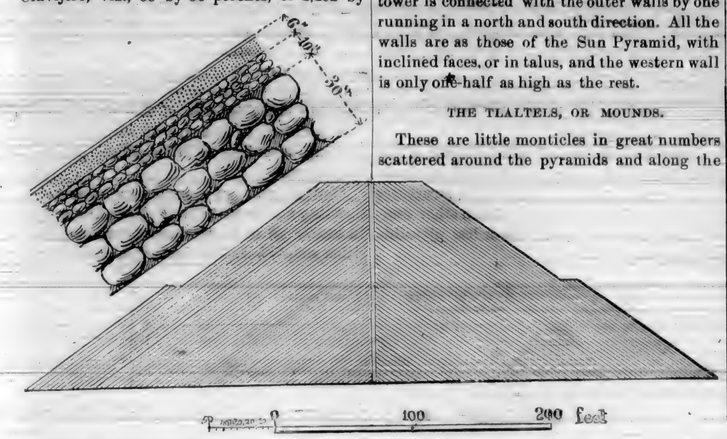
As the name indicates, this is an inclosure in the shape of a fortification. Four walls 1,000 feet long, each side, 260 feet wide, and 33 feet high, inclose a pyramid in the shape of the tower, common in old fortifications. The tower is connected with the outer walls by one running in a north and south direction. All the walls are as those of the Sun Pyramid, with inclined faces, or in talus, and the western wall is only one-half as high as the rest.

THE TLALTELS, OR MOUNDS.

These are little monticles in great numbers scattered around the pyramids and along the avenues of the dead, in groups, sometimes forming regular geometrical figures. Their outer form is a half spheroid, but they cover structures nowhere met with in similar monuments.

Each monticle covers a building, home, temple, mausoleum, or whatever it may be. Though connected with one another, they are isolated in their greater part. With a circular or poligonal plant they have only one side connected with the adjoining buildings. The floors and walls are admirable, though made of dry mud; they are covered with a composition of lime and metallic oxide, that would shame our best cements, Roman, Portland or Rosendale. The hard finish of those walls is made of a stucco not to be compared with our plaster. After a lapse of centuries (no one knows how many) they are so bright and shining that it gives pleasure to behold them. The floors are without cracks, without using Schillinger's patent.

Some of these *tumuli* have been broken open for treasures, building materials, or archeological objects, more for the former than latter. In all of them have been found vases and objects of art. In some, beautiful ornaments of silver, gold and stones.



Megalithic structures were so abundant that they can be seen used for house building, roads and bridges in the country around. I saw many in the neighboring town of San Juan of Teotihuacan, which would honor any museum in the world. And yet the Mexican Government suffers them to be destroyed, and loses not only objects of intrinsic value, but the key to unlock many of the secrets of the Ethnography of this continent. There is not in any one spot on this continent as much material together as in Teotihuacan. It would be worth the while of any society of wealthy American to send a scientific commission there. In one day I gathered more than 2,000 penates, and as many obsidian arrow points and knives. I acquired two large idols and several vases, which, however, I lost in Acapulco by being ignorant of the Mexican law of Treasuretrove.

In the avenue of the dead, opposite the Pyramid of the Moon, lies, abandoned and exposed to the dilapidations of the weather and vandals, a monolithic statue which may be *Mextli*, the one alluded to by the early Mexican historians, said to have been on top of the Pyramid of the Moon. It is eleven and one-half feet in height, and five and one-half feet on each side. It must weigh no less than 18 tons. These monuments are supposed to be the most ancient built by the hand of man in this continent. Who were the builders is not known. Betancourt says it was the Mexicans, but all other authors say that the Mexicans, when they arrived at the valley of Mexico, found these pyramids already built. Father Siguenza says it was the Olmecas, but that race has left no remains of their architecture, or records, upon which an opinion can be formed. Clavijero and Torquemada think they were built by the Toltecas, by whom the pyramid of Cholula is supposed to have been built. Sahagun says it was the Totonacos who built them. Mendoza, from geological consideration, ascribes to these pyramids a greater antiquity than any of the above-named race attained, and infers that they were built by a prehistoric race. No matter which race built them, they occupy, in the history, tradition, and legends of all of them, a most prominent place. The ground where they are placed was the Holy Land and the Mecca combined. The name Teotihuacan implies it.

The early writers translate it "*The city of the gods.*" Mendoza translates *Teotl*, God; *otli*, road; *huan* and *can*, close to; or "a place, close to the holy road." My friend Agustin Ziehl, translates, *Teotia*, to worship; *huan*, plural termination; *can*, as before; the whole, "Oratory, or place of worship."

In that spot the Indian tradition says the gods assembled after the world was created to metamorphize two of them into the *sun* and *moon*, and, according to some of the traditions, the pyramids were built at that time by the gods. When the Toltecs were tyrannized by their kings, they went in peregrination to Teotihuacan to propitiate the gods, who, however, destroyed them.

These traditions, ridiculous as they are, show the veneration which all the Indian races had for their pyramids.

The object in view of the builders of the pyramids is also surrounded by darkness, and only by a minute study of the structures themselves and a comparison with other similar ones, may we form more or less plausible conjectures.

Half a century ago, Champollion's discoveries gave the key to classify and understand the wonderful monuments of Egypt. The deciphering of the cuneiform character has thrown light to arrange and establish the dates of the temples and palaces of Nineveh and Babylon. All the Greek and Roman structures have been surveyed, illustrated, classified, and described minutely. The Dagobes and rock-cut temples of India have been brought to the reach of tradition and history, and have shown that those of Burmah, Cambodia, or China were not so remote that their origin could not be traced. Only the monuments of America still defy the endeavors of Americans to wrest from them the secrets of their history.

The builders of the pyramids were utterly illiterate, and have left no written record of their erection, nor are there any legible inscriptions on the stones, found on or around them, which offer any hints to the inquirer. They are in this respect similar to the old world monuments known as Barrows Cairns Giant's beds, Bazinas howes, Tumps, Lowe, etc.

And, as Ferguson says, "Till antiquaries are agreed whether the dolmens are monuments of the dead or altars for sacrificing men, whether the circles are temples or tombs or observatories, whether the mounds are tombs or law courts, it seems impossible, without arguing every point, to say anything that will be generally accepted."

If we cannot hope for the exact determination of the time of building the pyramids, or the race that originated them, however, we can find striking resemblances to similar structures in both continents.

We find in the old continent the everybody's-known pyramids of Egypt, with a great resemblance to our own. Their size is not very different; the areas covered by the two largest ones, in both hemispheres, are nearly the same, whereas the smaller Mexican pyramid is, in areal size, between the Great and Superior in Egypt. It has been stated by nearly every writer on the subject, that the American pyramids, like the Egyptian ones, were oriented by the cardinal points; but it is not so. On the contrary, it is a distinguishing characteristic of the structures on this continent, to be nearly all with their sides running according to intermediate points of the compass.

Another point of resemblance consists in that they are associated with funereal remains. In nearly all such structures human remains, either simply buried, or incased in cists or urns, are to be found. It has been made a subject of many studies, and the origin of many theories, the possible use to which the Egyptian pyramids could be put for astronomical purposes. The pyramids we are considering have no apparent device by means of which they might be made serviceable for that purpose. We might say, borrowing a botanical expression, that the pyramids in the valley of the Nile, and those in the valley of Anahuac, are of the same *genus* but of different *species*.

The geographical distribution is also remarkably similar in both continents. Starting from the north, we find them in England and Scotland, especially in hilly countries; in *tumuli*, *dolmens*, *avenues*, *circles*, and the fanciful Dracontia of Dr. Stukeley, attaining the greatest dimensions at Averbury and Stonehenge. In Ireland, we find similiar structures all over that country, under the names of cairns, which are specially described in the accounts of the battle circles of Moytura.

The tumuli, dolmens, and other monuments of the like, are very numerous both in Scandinavia and North Germany. To the Danes the credit is due of the first attempts to a systematic classification. We find them also in France and all the countries bordering the Mediterranean Sea. In Algiers and Tripoli they are numerous, and some in Algiers resemble those of Teotihuacan in the connection of the tumuli by rows of stone. The islands of the Mediterranean afford also many samples of these monuments, sometimes of great beauty and splendor. They extend themselves to Palestine, India, and the Siberian steppes. In Europe, as well as in Asia, they attain the largest dimensions and the most beautiful forms in a zone not far from the tropic of Cancer.

If now we come to this side of the Atlantic, we find them at the south of the shores of the Great Lakes, and spreading themselves easterly as far as the western boundary of the State of New Jersey, and westerly as far as Oregon and even Vancouver Island. The finest specimens of these structures are to be found along the great rivers Missouri, Mississippi and Ohio, generally on their borders and on alluvial soil. The Marietta works and Pyramids, on the banks of the Muskingum River, as described by Squier and Davis, have many points of resemblance to the Pyramids of Teotihuacan.

Going northward they change their form from the spherical to the pyramidal, and improve both in size and shape, attaining the best form at a zone not far from the tropics, thus resembling in their geographical distribution the monuments of the old world. Another feature is that, in proportion as we go northward, what the mounds lose in importance, the inclosure gains in extension, so that, in the old continent, the latter are either absent or of little importance, in Egypt or India, attaining an extension of several miles in the northern countries.

The same occurs in America. The walls, that in Teotihuacan measure scarcely a few thousand feet, reach, in Ohio, several miles, and assume all kinds of shapes. It seems as if the mound builders had started from near the tropics, where they held undisputed sway, and, going northward, had to protect their buildings with fortifications and other works, from the aggression of hostile tribes. The similarity of these structures raise, naturally, the question whether their builders were from the same race in both continents; and, if so, whether they emigrated from the Old Continent to the New, or *vice versa*?

Among the penates, or little figures, I found in Teotihuacan, there are all the types of mankind. The resemblance cannot be accidental, as they are found with even the same ornaments used by the respective type races. It seems as if people of all the races, known to us, had inhabited the Valley of *Anahuac*, or that the races which inhabited that valley were acquainted with all the races, and had perpetuated them in their statues. But, then, the same resemblance is found in the flora and fauna of both countries, and we are forced to conclude that either similar conditions of land, position, and climate will produce the same organisms, with similar tendencies, or that the earth, in her cosmogonical and geological life, has, by means of her changes of rotation, upheavals and depressions, uncovered, and immerged successively all her surface, and gradually shifted the organized world from one place into another.

In the utter impossibility of determining the history of these monuments, the Danish antiquarians have classified them in three classes:—

Those belonging to the remotest age, in which no metals of any kind were known to man; and they have called them as belonging to the "Stone Age." The Stone Age they suppose to come down to about 2,000 years B. C. The monument in which, besides the stone relics, copper, gold and brass are found, they place as belonging to another age, called the "Bronze Age," which comes down to our own era, in which time, iron, they suppose, began to be used.

This classification is obviously incomplete, inasmuch as most probably before they used bronze, man used gold, copper, and tin, which is found in many instances pure, in a native state. Besides, a great period of transition must have elapsed between two successive ages. In our country they have been classified according to the probable purpose for which they were built. That of Squier, Davis, and Lapham, is as follows:—

1. Inclosures for defense.
2. Sacred and miscellaneous inclosures.
3. Mounds of sacrifice.
4. Mounds of sepulture.
5. Temple mounds.
6. Animal mounds.

The Pyramids of Teotihuacan would be classified by Danish antiquarians as belonging to the Bronze Age, as different tools and ornaments have been found within them, though never iron has been found. According to the American classification, they belong to all the several denominations, excepting the last one.

They were inclosures for defense, as shown by the walls, excavations, and strategical position they occupy. Besides being placed in the highest part of the valley of Mexico, they were walled on the pregnable sides. Dr. Manfred, a member of the Mexican Geological Society and one of those sent by that society to explore those monuments, thinks that the well or shaft found in the interior of the Pyramid of the Moon is the entrance to a gallery going to the Pyramid of the Sun. He states to have seen similar structures in New Zealand, and in the Pampas of Sacramento, in South America, which the natives call Pahs. Each pyramid, or mound, has a central well, which gives entrance to galleries going to long distances. When the natives are attacked he says they defend the mounds to the last, but, if overpowered, they dissappear through the wells, and make their escape to long distances. He thinks that a proper exploration would show that both pyramids are connected by a gallery.

Close to the citadel I found large heaps of obsidian arrow points, and on the neighboring river many boulders of the same material of which the arrow points are made. I presume there they had their arsenal. They were "sacred inclosures" inasmuch as, according

to tradition, the Mexicans assembled around them to propitiate their gods.

The Mexicans sacrificed prisoners, both to the sun, *Tonatiuh*, and to the moon, *Meztli*, consequently the pyramids must have been used as "Mounds of Sacrifice."

That they were Mounds of Sepulture is implied by the *Micoatl*, or Avenue of the Dead, and attested by the cists or urns and funereal objects found in the *Tlatles*, or Tumuli.

Finally they were "Temple Mounds" dedicated to *Tonatiuh* and *Meztli*.

What a horizon is surveyed by a traveler on top of the Meztlizacoalli! At his feet the sacred Valley of Teotihuacan, one of the most elevated in Mexico, fertile, and perpetually green, surrounded by hills, like an amphitheatre. The silvery heads of Popocatapetl and Iztaccihuatl penetrating high in the sky on one side, and the snow-capped Toluca in the opposite, all full with traditions. Close by the town of San Juan, the only one that tradition mentions from prehistoric times. There is where the wise men of Anahuac assembled together to organize their wonderful calendar. There the learned and pious Huemac wrote the Teoamoxlit or American Bible; there, in remote ages, took effect the symbolic, mythological metamorphosis.

Of all that splendor and glorious achievements, what remains? In the words of Rioja:

"Sad relics, sad and vain,
Of those invincible men
Who held the region then."

[Lecture delivered by E. J. Molera, before the Geographical Society of the Pacific.]

Notes about Saws.

THE Germans use at the present day among their furniture makers, carpenters and joiners, thirteen different varieties of saws, each one of which has its own peculiar size of the teeth, as well as a different relation of the teeth to each other. How important the thin saw blade is, not only as a means to save power, but also as a means to save wood, can be seen from the following: A log of walnut, four meters long, and one meter diameter, cut into twenty pieces by the new horizontal saw frame, saves thirty millimeters of wood when compared with the cutting of the old fashioned vertical saws. This is equal to a profit of $9.00 to $12.00. For Germany, where annually 100,000 cubic meters of this wood is used in the various industries, this would represent a saving of $37,500 to $50,000.

The greatest enemies of saws are the particles and pieces of iron found in woods; these are often driven in some form into young trees and succeeding growth covers them up entirely. A curious collection of such ingrown iron particles was recently exhibited in Germany. It had been obtained from America, Prussia, Germany, Spain and other countries, and exhibited the queerest forms of wood formation covering particles of iron of various shapes and sizes, whose presence was revealed only by the breaking of the teeth of the saw, and which without the cutting would have remained invisible to the human eyes.—*The Lumber World.*

Save Your Chisel Handles.

ALL carpenters know how soon the butt end of chisels split, when daily exposed to the blow of a mallet or hammer. A remedy suggested by a Brooklyn man consists simply in sawing or cutting off the round end of the handle so as to make it flat, and attaching by a few small nails on the top of it two round disks of sole leather, so that the end becomes similar to the heel of a boot. Two thicknesses of leather will prevent all further splitting, and if, in the course of time, they expand or overlap the wood of the handle, they are simply trimmed off all around.

IT is well known that the round form is the best for chimneys in workshops. It facilitates the escape of smoke and gives less hold for the wind, besides requiring less material for construction. Round chimneys are, however, difficult to build, and in some places the want of workmen able to make the round kind has compelled the adoption of square or octagonal forms. To obviate this a European firm makes bricks in the shape of wedges, and corresponding with the radius the chimney is to have.

WHITE paint that has become discolored may be nicely cleaned by using a little whitening in the water for washing.

THE most universally recognized rule for determining the height of a room is the sum of half the width and the square root of the length. The adoption of this rule results in bringing the angle formed by the ceiling and wall just within the angle of vision of a person standing in the center of the room, without raising the eyes; but of course the rule can only be strictly observed in one room on each floor, unless a double tier of joists is set above the smaller rooms, or unless it is possible to have the floors of rooms in the same story on different levels, either course involving difficulty and expense.

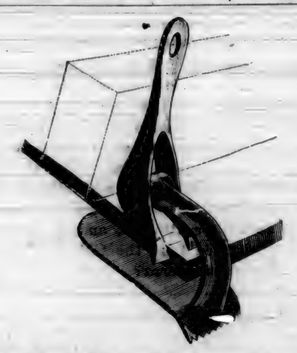
TO CLEAN red brick floors rub them with a brick of the same color, moistened with a little warm milk and water, and wipe dry with a soft cloth.

Buck's Architectural Designs.

WE now have a full supply of this new work on hand, and will forward a copy to any address upon the receipt of FIFTY CENTS.

Promptly forward your subscription for 1884.

KENNETT'S PATENT ROOF BRACKET.



This Bracket is used to instantly secure a Scaffold or Staging on a Shingle roof,

Without the Use of Nails or Screws.

It is made of best **Malleable Iron**, and cannot be broken.

The above Illustration shows the Bracket partly under a shingle and a scantling, in position. By this construction it forms a clamp, and the more pressure there is against it the tighter it gets. The bracket is placed over a joint, so that it holds on to three shingles and makes it doubly secure, and obviates any possibility of slipping or of splitting shingles.

The scantling lies close to the roof, so that loose nails and shingles cannot pass down and off the roof. It engages with thick or thin shingles with the same readiness and security.

IT IS THE SAFEST MODE
In the World
OF FASTENING A SCAFFOLD.
It Cannot Slip or Give Way.

For Shingling, Repairing, or Painting a Shingle Roof, or in case of a fire, to go on a roof it has no equal. It requires but a few seconds to change from one place to another, requires no nails, splits no shingles in taking up your scaffold, as in the old way.

Price, $4.00 per Dozen.

In order that every mechanic on the coast may possess these Brackets, we will send a pair, post-paid, to any address, upon receipt of **75 cents**. ADDRESS this office,

240 Montgomery St., San Francisco, Cal.

MASONS' and BUILDERS' EXCHANGE OF SAN FRANCISCO,

Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

Thanks.

THE CALIFORNIA ARCHITECT AND BUILDING NEWS is the most practical and sensible Journal printed on the Pacific Slope. It has literary merits that make it agreeable reading, and its practical articles, designs, and illustrations are pertinent to its purposes and must be extremely useful to the architects and builders of all sections of the far West. Messrs. Jas. E. and Geo. H. Wolfe, have displayed considerable judgment and remarkable vigor in working their paper to its present high position.—*Decorator and Furnisher of New York.*

Shavings and Saw-dust.

A NEW work by J. Kane, of Rochester, New York. It treats especially of the designing, construction, care and operation of wood-working machinery. The work is especially valuable from the fact that the observations given are those of a practical machinist and one who presents his views instructively and entertainingly. Every wood-worker should possess a copy of this work. Sent post paid upon receipt of $1.50.

Malleable Iron Castings and Fences.

PARTICULAR attention is called to the new and artistic designs of malleable iron castings and fences now being successfully introduced into this market by the Phœnix Iron Works. See page ii of this issue.

Steel Sinks.

EVERY new building should have their kitchen furnished with one of these new sinks. Old wooden sinks should be removed to make place for these neat and cleanly appurtenances. See page ix.

Venetian Blinds.

D. S. BROWN & Co. have been appointed sole agents for these beautiful adjuncts to windows. Architects are especially invited to examine the merits of these blinds. See page xii.

Gas Machines.

THE Royal Gas Machine, through their explanations on page iii of this issue, calls particular attention to the merits of their improved Gas Machine. Send for circulars.

Wood-Working Machinery.

ADDRESS a letter to Goodell and Waters, Philadelphia, for information in regard to all the latest improvements in wood-working machinery.

"YOU have asked to see me?" said an employer to his clerk. "Yes, sir." "What is wanted?" "I wish to make a claim, which I doubt not your sense of justice will accept." "Very well, what is it?" "I do the same work as Z, and I am paid five dollars a month less than he. Is that fair?" "No; you are perfectly right. I will at once reduce Z's salary five dollars!"

BUILDING NEWS
Published on the 15th of each month
BY THE
San Francisco Architectural Publishing Co.
JAMES E. WOLFE, GEO. H. WOLFE,
EDITORS AND MANAGERS
Rooms 11, 12, 13, No. 240 Montgomery Street.
TERMS:
PER ANNUM $2.00 IN ADVANCE
ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.
Front Cover, outside, each insertion, $2.50 per square.
Back Cover, outside, each insertion, $2.00 per square.
Page preceding reading matter, $1.75 per square.
Page following reading matter, $1.50 per square,
Inside Pages, each insertion, $1.00 per square.
Full Page, inside, one insertion, $40.00.
Each subsequent insertion according to agreement.
A square is seven-eighths of an inch in length by width of column.
Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.
NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.
When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

Result of our Competition.

IN our January issue of this year, the proprietors of this Journal offered four premiums, amounting to $175, for the four best plans for a country dwelling to cost about $5,000. It was stipulated in the offer made, that all plans were to be in this office on or before the first day of May.

With the result as far as the number of plans is concerned, we are well pleased; much interest was taken by both Architects and Draughtsmen in various sections of the country, and the plans presented, as a whole, are meritorious in design, neat and skillful in execution, and are decidedly original in conception, the only fault being that, as a rule, the estimates are too low for the designs presented, without a single exception.

The committee from the S. F. Chapter of Architects—Messrs. Sanders, Pissis & Mitchell—met in our office early Saturday (May 10) evening, for the purpose of examining the plans presented. Each one was carefully considered, and the defects and beauties of each plan were noted. From the number of plans, much time was taken and it was midnight when they adjourned. They will meet again this week, when the award will be made.

Plans presented by the following parties, are the ones selected from which the successful four will be drawn:—

Garrick.
As You Like It.
P. Nutt.
Oriole.
Tease Quare.
Alaska.
Hoosier.
T. L. W. K.
O. K.

The proper names and addresses of the parties entitled to receive the premiums, will be given in our next issue. Notification, however, will be sent by mail as soon as the award is made. The committee will not be informed of either name or address until their report is prepared. Drafts for the amounts offered will be sent to the successful competitors as soon as the decision is announced.

The Pioneer Hall.

RESULT OF THE COMPETITION.

The building committee of the Pioneer Society, after receiving the report of an expert upon the merits of the various plans presented, selected those presented by

Wright & Sanders,
Percy & Hamilton,
W. Patton,

as the three best, and awarded to each equal premiums of $500, the first-named securing the honor of furnishing the plans, and superintending the erection of the building.

Much dissatisfaction is felt at the result given. Had the building committee selected *three* experts, the feeling among the unsuccessful ones would not have been so bitter; but, in the case in point, when so much time and money had been expended in preparing plans, it is justly held that the decision should not have been left to *one* man, as too much power was thereby placed for such an important decision.

The whole arrangement, from its inception, has turned out similar to previous competitions held in this city. This Journal pointed out plainly the many absurd requirements of the rules governing the one in question, and we were much surprised at the number of first-class architects who almost knowingly wasted their time and money in preparing plans. We hope the architects of this city have received a lesson from the way the Pioneer Hall competition has been conducted.

High Price of Bricks.

PROPOSED REMEDY.

A HEALTHY state of building operations in any large city is always sure to be the means of local combinations among material men, the effect of which is to raise the prices of nearly everything connected with the building trades, and oftentimes to a point that compels owners to stop contemplated improvements; San Francisco is no exception to this general rule. No matter how great a depression may have existed, as soon as the least ray of light breaks in upon the general gloom, the material men combine, and, as a result, prices are gradually raised until they become so great that operations in the respective branches of trade are almost stopped; then prices are lowered until another demand is created, when the same process is repeated as before. And this battledore and shuttlecock game is played over and over again to the infinite disgust of those who desire to see materials and wages at a price satisfactory to both producers and consumers.

In several issues of this Journal, we have shown that the prices of lumber are and have been much higher than a fair, legitimate profit will warrant. And now when property owners are willing to invest money in substantial improvements, expecting for a while but a small income from their outlay, the price of brick is held at a figure totally inconsistent with the cost of production.

The lowest price for which good, hard-burned brick can be purchased at the present time is eleven dollars per thousand, the only concession granted being one per cent. discount for cash. In addition to this price, from 50 cents to $1.50 per thousand is charged for hauling, depending altogether upon the distance. At the price given there is a clear profit of at least three dollars per thousand. In a small building where only a few thousands are necessary for foundations and chimneys, the cost is not much increased; but on the new Odd Fellows' Hall, where nearly four millions are required, the case assumes a totally different aspect.

This state of affairs has received careful study from those most interested, and more than one project is on foot, to counteract the designs of those holding the brick supply in their tight grasp. Among other things, the advisability has been considered of the Master Masons themselves combining and starting a manufactory of their own, thus in a great measure making them independent of the syndicate now controlling the market.

We can see no good reason for a project of this kind not being a successful one. Unity of action and strict obedience to a well digested set of rules will enable the leading masons to form a company that, with judicious management, can so regulate the supply of brick and the price thereof that owners can make preparations a long way ahead for building, feeling sure that they can make calculations on the cost of improvements and thus determine if the same will return a profitable income.

There can be no question but that some arrangement will be made before next year's building season will commence, to regulate the price of bricks, and still leave a fair profit to the manufacturer. We understand that one of the largest consumers of brick in the city has taken hold of the problem, and if his intentions are carried out as stated to us, the price will be materially lower in the near future.

In this connection, we would suggest that the matter of masons' wages become an important one. Patterning after the example of the manufacturers, whenever labor is in demand up jumps the wages to as high a standard as the owners will bear, and when work is scarce on account of the great cost of materials and labor, the price gradually drops. One of the great questions to be considered is, Can a standard of wages and prices of materials be adopted, so that owners can calculate in the future the cost of any desired improvement.

Building Without Plans.

THE carpenter or contractor who is emphatic in his assurances that plans and specifications are not necessary may be likened to a druggist who should propose to furnish the medicines for a serious case of illness without the doctor's prescription; or to an opponent in a case at law, who should make the absurd proposition that he and his lawyer could settle the question without the aid of a judge and counsel on the other side. The relations of the owner and contractor must always necessarily resemble a case at law. The contractor's knowledge of the business is his counsel, the architect is the owner's counsel, and the plans and specifications are the judges. The best way to keep out of a real case at law is to provide this silent little court to settle every question.

The Increasing Prospects of this Journal.

WE once more renew expressions of gratitude for the handsome patronage extended to this journal, both in subscriptions and advertisements. It has by far exceeded the highest expectations of its founders, and if earnest efforts will accomplish it, the future will be no less a triumph than the past has been.

It is pleasant to listen to the very many complimentary expressions volunteered by patrons—personally strangers to us—known only by the feelings of friendship brought about through the influence of what has appeared from time to time in this journal.

It also greatly pleases to have a large number of our advertising patrons tell of the returns received, and the business advantages derived from advertising in our columns. We shall not "blow our own horn" in this regard, but refer those who have not, to those who have continued their advertising in this journal. Judicious advertising always yields a fair return for the money spent.

The Painters' Strike.

THE maximum rates of wages paid to journeymen painters up to the present time, has been $3.00 per diem. Recently, however, the spirit of dissatisfaction has manifested itself among the daily toilers with the brush and paint-pot, resulting in the demand for $3.50 per day, which being not acceeded to by the bosses, a strike has resulted.

Up to present writing, just prior to going to press, no general concession has been made by the master painters, although some have been compelled to comply with the demand for an advance, for the purpose of completing work under way, within the limits of contract time, and to avoid liquidated damages. A few of the employers, for reasons of their own, have yeilded, and in time there may be a general concession.

The opposition to the advance, on the part of the employers, is not based so much upon the financial feature, for in all cases of contracts taken after the advance becomes the rule, the difference can be provided for in the estimates for new work. But it is a well-known fact in painting circles, and among mechanics generally in other branches, and to architects, that adulterations of paint materials is a common practice with a certain class of master painters, who take work at prices that pure stock cannot be afforded, using various compounds composed of ingredients containing no elements of white lead and oil, and by this and other unfair means, deprive men who do honest work and use proper materials and are unwilling to degrade the painting art, from anything like a fair show in the field of contracting. And the better men realize the disadvantage at which they are placed, for the frauds can better afford, with the use of their abominable pastes and slushes costing but little to prepare, to pay $3.50, than competent and worthy men can afford $3.00, using the pure articles.

The hitch is mainly upon this ground; the better class of bosses feeling that there should be something done in the way of exposures of things existing and practiced daily in the painting business, to equalize matters, so that the public may be able to understand matters fully, and know who are *painters* in the right and true signification of the term, and who the men that roll up their sleeves and manipulate with their hands and arms, stuff that they call paint, but which contains not one-twentieth part of pure paint stock, which they palm off upon, and deceive owners with, while those who will not descend to such perversion of the mechanical art, have less to do than they should have, and suffer financially by being crowded out in so many cases, by reason of owners, for the sake of an *apparent* saving in first cost, accepting the "slush heavers" at a low figure, rather than paying a fair advance over fraud prices, to good and reliable men for good work.

For Architects.

ARCHITECTS who practice in the large cities will be interested in the answer given by the law editor of *La Semaine des Constructeurs* to a correspondent who asks whether the usual commission can be collected, where old materials are used in building, upon the cost of the work as it would have been if all the materials were new. The reply to this important question is a very satisfactory one, at least for architects in France. It appears the judicial decisions have established the law there that for his services in the construction of a new building an architect is entitled, in summing up the cost upon which his commission is calculated, to reckon all materials, whether old or new, and whether furnished by the proprietor or not, as if new and furnished by the contractor, the courts holding that the work and responsibility of the professional man, and his proper compensation, are the same in both cases. Moreover, if, as often happens in cities, the demolition of structures already existing on the ground forms a necessary preliminary to the construction of a new building, and if the architect of the latter includes in his service the direction of the work of taking down and sorting the old materials, and the provisions for the protection of the public, he is entitled in France, by a decision of the Tribunal of the Seine, to collect commission upon the cost of these operations, in addition to his fees for work upon the new building.

Compiled Items of Interest for Mechanics.

Finishing Saws.

A LATE improvement consists in tempering and straightening the saws at one operation. This is done by heating the saws to the proper degree, and then pressing them with a sudden and powerful stroke between two surfaces of cold iron. A drop-press is employed for the purpose. The mechanism is quite simple and inexpensive. Its use is said to effect an important economy in the manufacture of nearly all kinds of saws and improve their quality.

Street, Store and Bank Fronts, $4.00

IN filling up cracks and breaks in walls, painters experience a great annoyance from the rapidity with which the ordinary plaster of Paris and water "sets." A remedy will be found in using vinegar instead of water. Mix the same as if water was used, and the result will be very much like putty, and will remain plastic for about a half an hour, finally becoming perfectly hard.

Cottages and Villas $6.00

GLYCERINE GLUE.—A German chemist has discovered that the strength of glue is very greatly increased by the addition of one-fourth as much glycerine as glue. Glycerine has many other uses, among which one of the least known is its property of removing pencil marks from paper in a very perfect manner. It may also be combined with starch and plaster of Paris, to form one of the most durable cements for various kinds of apparatus.

Builder's Guide $2.00

GRECIAN mythology tells us that the inventor of the saw once found the jawbone of a snake, and used it to cut through a piece of wood, then imitated it by jagging an iron plate, and thus made a saw.

Modern Perspective $6.00

IT is reported that the carpenters and sawyers of Paris have made the singular proposal that a tax shall be put upon all machines used by their employers, according to the work they perform.

Wooden and Brick Buildings ... $18.00

INDIAN ink running. If it is for drawing plans you may prevent it running by adding a little sugar to the the Indian ink.

How to Make Cisterns.

CISTERNS, as a general rule, should be made as deep as possible, for the sake of coolness and economy, because it is easier to arch over a cistern twenty feet deep and twelve feet in diameter, than one twelve feet deep and seventeen feet in diameter, and these would be of equal capacity. The following table of the contents of the various sized cisterns may be of interest in this connection: For each ten inches in depth the following diameters will give the contents named: 8 feet, 313 gallons; 9 feet, 396 gallons; 10 feet, 489 gallons; 11 feet, 592 gallons; 12 feet, 705 gallons; 14 feet, 959 gallons. Double these diameters will give four times as much capacity.

Church Architecture $4.00

CREASES in drawing paper or in engravings may be removed by laying the paper face downward upon a sheet of smooth, unsized white paper, covering it with another sheet of the same, slightly damped, and then iron with a warm flat-iron.

Practical Carpentry $1.00

ONE of the most important features in an interior arrangement is the actual and relative height and width of doors and windows. The question is whether the apparent proportions of apartments cannot be greatly modified by the treatment of the necessary openings. A window in the center of one side of a room gives more light than if at one side of the center, but it has the effect of shortening the length of that side. The same is true of doors in similar positions. The higher a window is the more light it will give, but the lower the room will appear. In doors, nothing is gained by increasing the height beyond a proportion to the width that shall prevent a stunted appearance. Their relative height to that of the windows is a nice question of balance, that can be best determined by experience.

Universal Assistant $2.50

VARNISH and paint can be removed by a solution of caustic soda. The operation may have to be repeated several times, depending upon the thickness of the materials to be removed.

COAL Oil is soluble in Ether, Naptha, Chloroform, etc. Stains in carpets made by the oil, with proper manipulation, can readily be removed by either of the above reagents. Care should be taken not to have a light around while making the experiment.

Buck's Practical Designs 50c

LIQUID GLUE.—4 ounces hard glue, 16 ounces acetic acid; dissolve by soaking and heating. Spaulding's glue is supposed to be ordinary glue dissolved in good, strong vinegar. Another way is to add a little pyroligneous acid to a thick solution of glue and water.

Cummings' Architectural Details $6.00

THE apprentice system is finding strong advocates, not only among employers, but among intelligent workmen and trade-unionists, who have heretofore opposed the system. Skill always pays, always is in demand, and always commands better compensation than where it is lacking.

Bancroft's Histories.

THIS magnificent work embraces a complete history of the Pacific States. The territory covered is the western half of North America, from Panama to Alaska, including all of Central America and Mexico, and is equivalent in area to one-twelfth of the earth's surface.

There are to be thirty-nine octavo volumes, with maps and illustrations, fifteen of which are now ready. They will be well printed on good paper, neatly and substantially bound, uniform in style, and will average over 700 pages each. Three or four new volumes per annum will appear until the entire series is completed. Subscribers will not be obliged to take the work unless it corresponds with the description in every particular.

	PER VOLUME.
Bound in Extra, English Cloth, neat and attractive style	$4.50
Bound in fine leather, Library Style	5.50
Bound in half calf, half Russia or half Morocco	8.00
Bound in Russia Leather or Tree Calf	10.00

Any information in regard to the above will be given by addressing the office of this journal.

Old English Homesteads.

BY A CURTIS BOND.

THE structural stability of old English dwellings and the massiveness of their material, has preserved a vast number of them dating centuries back. In the superior class of residences there is ample provision for indoor comfort, whilst the prevailing disposition was to put wood to its best account in turning and carving, and to hide the nakedness of walls by paintings, which, if gaudy, were at least suggestive.

It is noticeable that in houses of any pretentions the ornament was such as to give it a distinctive and appropriate character. The room of Mary, Queen of Scots, at Hardwich House, Derbyshire, has panels of inlaid woods representing profiles of the Cæsars. The state-room walls are divided in half the upper portion, having landscapes and figures on a white ground, tapestry covering the lower portion.

An early poet tells of a room on the walls of which appeared,

"Old portraitures
Of horsemen, hawkes and hounds,
And hart all full of wounds."

The designs were often only outlined or roughly filled in, but the scenic effect would be heightened by the light being admitted through narrow, casemented windows, and never too abundant.

The bedsteads, not infrequently placed on an elevated platform, were of so solid a character as to well merit the designation in wills and other documents, as "beds of tymbre." That of Henry VIII., now to be seen in Hampton Court, is described in an old inventory as having "postes and head curiously wrought." Old oaken chests, oddly carved, were invariable accompaniments of dining-room and sitting-room furniture.

Ends and backs of benches for the dining-table, massive and richly carved, were prominent features of the decorative *ensemble* and the extent to which ceiling decoration was carried, contrasts strongly with the prevailing plainness which succeeded, but the sunken panels, with carved borders, were in keeping with the walls of the room when of wood, and which, in paneling and coloring, were singularly ornamented.

Domed, scenic, oval, masonry recesses were frequently planned by architects to hold the side-board, and thus prevent them from obtrusively occupying the floor space. An immense amount of carving was often lavished on staircases, which, with their ample breadth, were always rendered a prominent feature, the effect being aided by the practice, from the time that glass came into general use, of lighting them from above. In old drawings of manors, with surrounding grounds, the garden pavilions in stone or brick, and composition or wood, on which much care and cost were lavished, form conspicuous features and are suggestive of a departure in architecture with ourselves in this line. The pediments of many of these wooden temples, in rustic or classic form, were adorned with figures of satyrs, the graces, griffins, dragons, etc., in short, all descriptions of vagaries, not to be too critically scanned, serving to gratify the sight, the sport of fancy breaking away from the conventional styles of more permanent erections.

Evoluting from the early house of the past generations of Englishmen to the present business house of New York City, is a progression by no means so violent in its change as would appear at first sight, for the constructive qualities of both are worthy of especial notice in their stability. The architect of the modern building has discovered that permanency in his structure is an element essential to their appreciation and necessary for his own reputation. In fact, singular as it may appear, more attention is given in New York to the construction and substantiality of business buildings than of residences. Dwellings, where possibly a dozen different families are congregated, on fashionable flats, renting from $2,000 to $6,000 each apartment per year, are made in a flimsy and precarious way when compared with the magnificent stone buildings constantly being put up in the lower part of the city. The protection of human life, in a word, is a secondary consideration to the safety of books and office furniture.

Early in May a large number of firms will remove their offices to a new building (referred to some months ago), on Nassau Street, between Cedar and Liberty, occupying the cite of the old post-office. Masons are busy laying the stone in the main hall, and plasterers are putting the finishing touches to the walls. Every day witnesses new crowds gathering on the corner of the streets thereabouts to study the ornamental features, which are so plentifully shown.

The building of the Mutual Life Insurance Company is destined to be an architectural attraction for the prescribed ten days, which is the duration of wonder in this country, and by the end of that time, no doubt, another edifice will have been started with novelties shown in its construction and ornamentation that will detract attention from the present. That, in its turn, will be eclipsed by other efforts, and so it will go on, as Dean Swift says, "*ad infinitum*."

The portico of the Mutual Building is two stories in height. The first story consists of large piers of granite, the alternate blocks polished and fluted. These are planked by two very handsomely polished Quincy granite columns. The frieze contains a panel upon which the title of the company is set in polished granite letters. The ceiling of this story of the portico is paneled with richly moulded squares, three in number, which inclose foliated rosettes, elaborately carved, all in strict conformity with the style of the building, which is Italian Renaissance. The capitals of the polished columns are of white Italian marble, decorated with handsomely modeled cap-work. The second story is of Indiana limestone. The piers, unlike those of the first story, are paneled, and enriched with elaborate carvings. Next to these piers are granite columns smaller than those below, and supporting an arch with a vaulted paneled ceiling.

The capitals of the flanking piers contain heads typical of Europe, Asia, Africa, and America. Europe is represented by the head of a Caucasian, Asia by the head of a Chinaman, Africa by a negro, and America by the everlasting Indian. They were modeled in Rome.

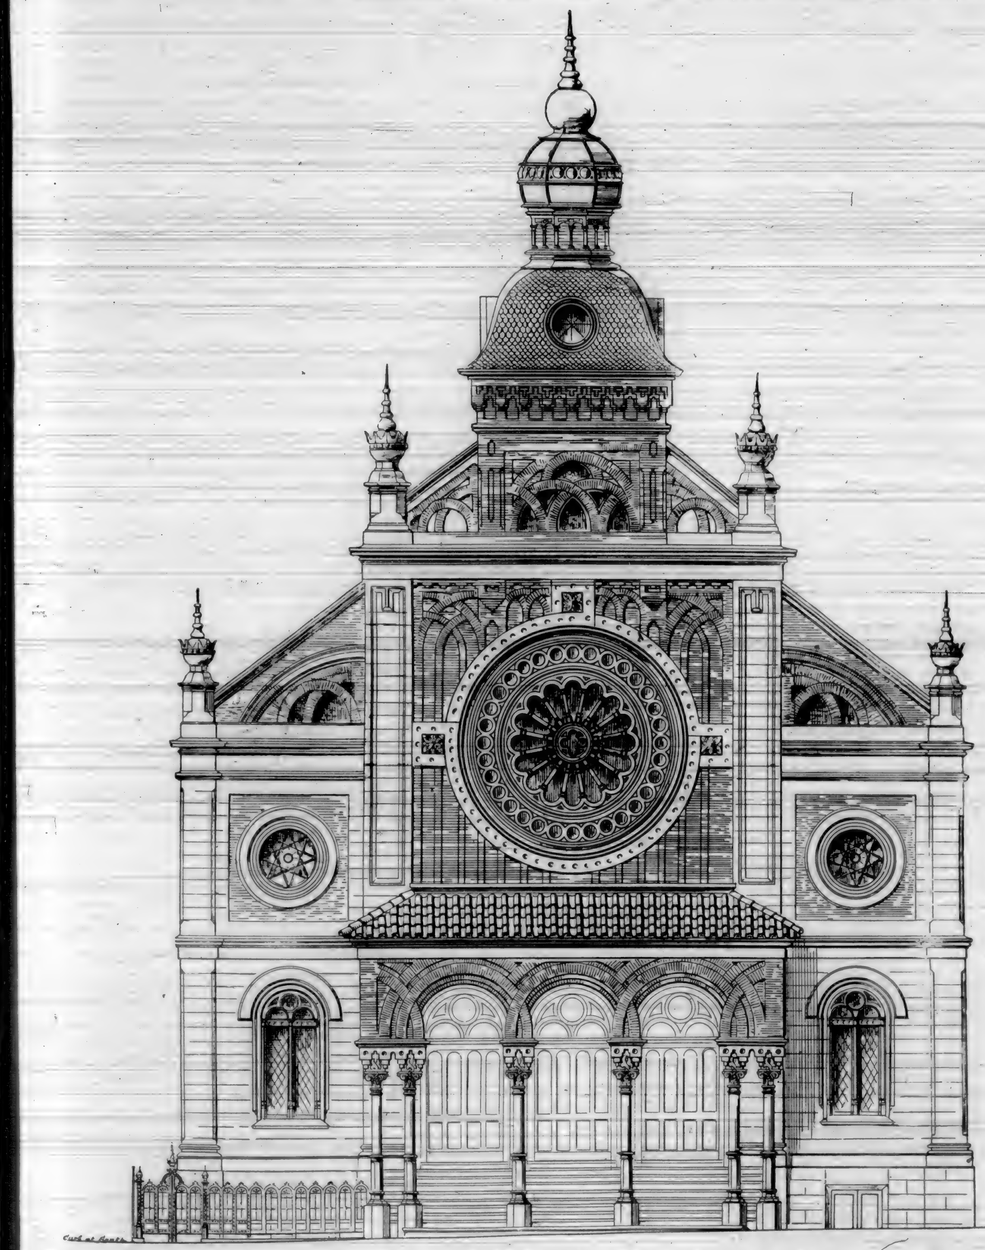
The whole building is so harmonious in its proportions that the size of the portico is really lost sight of, and is beyond what an ordinary observer would imagine. Its length is over 64 feet, and its breadth over 26 feet. The building is 185 feet in length on Nassau Street, 111 feet on Cedar Street, and 115 on Liberty. It is about 150 feet in height, divided between eight stories.

Wood carving has become, like stained glass, such an essential in architecture that it may now be considered legitimately as one of the phases of the art.

Carvings abound which show the limits and monotony of the art rather than the varieties of which it is susceptible. For pervading expression, all details must be brought into subordination to a governing purpose. It is this manifestation and not mere manipulative skill that gives carving its true value. At the same time technical methods must be used to the utmost, and especial care taken in transitions of form:—transitions which are often rough and rude to a fault, though displaying a certain kind of ingenuity.

There may be inequality in a carving and yet without blemish, as, for instance, when the objects in bold relief are highly finished, and the details somewhat sketchily worked out, but this sketchy aspect must be executed so skillfully as not to bear the appearance of slovenliness. Chopped-up execution and scattered details are to be avoided. The whole art does not consist in mere representation of objects in relief, but there is necessitated a certain unity of design which will be greatly aided by giving to each part its proper scale. As illustrating this latter point comes the following scathing English critique on a carved panel: "It represented a piece of French carving, and is a fearful and wonderful piece of art. It contains a rose which might be a cabbage; close by is a snail with a horse on his back; near the snail is a squirrel much too small, and a butterfly much too large, and, resting one foot on the roof of the snail-shell, sucking honey from a kind of fuchia, is a bird of such strange aspect that we have no choice but to conclude that at length we are privileged to behold a portrait of the eccentric chuck itself."

It cannot be too often urged that time and skill must be employed on the composition as well as on the execution, and that but a portion of the praise due to good, artistic carving is to be accorded to the manual labor. Carving may be indulged in as an amusement, but



FRONT-ELEVATION.

Scale: ¼ of an inch to the foot. Synagogue of the Beni Jeshurun, Madison Av.

let the aim be to embody in the work some feature of excellence. Of various devices by which special effects may be secured, may be instanced the emphasizing, by a number of small holes, the central portion of a leaf between the two projecting lines which represent the mid-rib, and the delineation or intersecting stems by making some more depressed than others. Some carvers show a tendency to substitute angular for rounded forms, thus directing the eye rather to sharp outlines than to broad surfaces, and to unduly multiplying parts which must be rendered proportionately minute. To please in minor details wood carving should exhibit a swift touch and an easy lightness in the rendering of the details.

Excellence in wood carving does not necessarily lie in the presentation of objects in the boldest possible relief. When the art was carried to its highest perfection in France, in the reign of Henry II., there was extreme simplicity of treatment, and the finest contrasts of light and shadow were obtained without high relief.

The obstructions to travel, and the annoyance of having the sidewalk occupied with the dirt and boards, essential accompaniments to the reconstruction of a building, has been such a cause of complaint in our city where existing buildings are constantly undergoing repairs, that means have now been adopted to avoid this sort of confusion. A bank recently erected in Wall Street found it desirable to absorb into itself the entire sidewalk in its frontage; and, to accommodate the traveling hundreds who daily pass that way, a wooden structure was put up forming a second sidewalk, elevated some five feet above the natural one. Pedestrians were asked to climb a few steps to reach this made walk, and the workmen wheeled the mortar and carried their material beneath. Over the wooden walk was a substantial roof to protect passers from an accidental brick that might possibly find its way from the upper stories.

Another excellent arrangement was recently seen on Twenty-third Street, where the owner of a corner building was adding three stories to its height. An enormous wooden funnel was constructed from the first floor to the roof, running up the side of the building at its extreme rear. At the first story the funnel turned abruptly at an angle and continued out over the sidewalk to the gutter, where it terminated in a pair of steps. The height of this arm or angle from the ground was sufficient to permit people in the street passing beneath it. An elevator ran up the funnel, carrying to the roof all the materials necessary for the construction going on. By this means the street was kept clear, and the occupants of the house were saved the dust from the walk and the unsightliness of dirty heaps about the doors.

Architecture has of late received much attention from the magazines. *The Century*, not long ago, had an article upon the architectural league of this city, and has followed that up with articles bearing more directly upon particular buildings. This month *Harper's* has the first of a series upon recent buildings in America—or rather in the United States, beginning with business houses, and presumedly intending to follow it up with residences, etc.

In this connection the prevailing craze might be referred to, that has taken possession of society ladies, which is to become authoresses, and those who have the "vital spark," are making efforts to fan it into a particularly lively flame. Several have succeeded and this paper to which I have referred, in *Harper's*, is one of that sort, being written by Mrs. Schuyler Van Rensaellaer. If this craze will last long enough to accomplish any good to the young ladies, it will be a most commendable fashion.

* * * * * * *

The illustration I sent this month is a departure fron the strictly country architecture which I have made it a point to furnish for the past few months. I am induced to illustrate this synagogue for the reason that it is the very latest building put up in the city, and is destined to be very prominent from the rich congregation that is to worship in it.

The style is the Moresque and the Architect is Mr. R. Guastavino.

Improvements in Men and Machines.

It would be a curious study to ascertain how far the improvement in machines and in tools had kept pace with that in the skilled mechanic. One thing is certain, at the beginning of the inquiry, that a skilled mechanic is of just as much value to-day as ever. How much he has improved is a question for scientific examination rather than one for absolute statement. It would be a queer assertion that the men of fifty years ago were inferior to those of the present. All the facts of the past, as well as those of the present, show that our present mechanics are no more mechanics than those of half a century ago All the great improvements in hand tools and machine tools for the last fifty years have come from the individual efforts of men who had done their work before the present advent of machine and automatic tools. These men—these workmen and inventors—made possibilities out of suggestions, and realities out of imaginings. To them belong the realities of the present machine shop.

It would seem from this that it is not the tools and the appliances that make the workmen, but the workmen who make the tools. There are just as good mechanics to-day, with all our mechanical appliances for good work, as there were when every job required a new arrangement of tools for work. In fact, the improvement in machines presupposes the capacity of the machine makers.

And yet, these improvements have their influence on the workman; the better the tool, the more exactive the workman. There are gray-headed, almost superannuated, workmen in our shops who have voluntarily discarded all their old time notions to take up with some "new fangled trick" that has been proved to be an advance toward perfection. Every improvement in tools—induced and perfected by mechanics—tends to advance in the true mechanical improvement of the workman.—*Scientific American.*

Tin Casing to Retard Flames.

The principal cause of the rapid spreading of flames, in modern buildings, is found in the fact that the elevator shafts furnish such perfect flues for making a strong draught. When, added to this, these openings through the floors of a building, from top to bottom, are incased with wood, alone forms the partition walls separating such a flue from the different stories, it will be readily seen that we have a surprisingly perfect arrangement for the quick spreading of a conflagration from cellar to roof. A cheap and easily obtainable means for partial protection from this danger, in buildings where the most improved construction has not been followed, would be to line the elevator shaft and the connecting doors and casing, as well as the car, with tin. This would not, of course, make these openings proof against the action of a fire which has been some time in progress, where the accumulated heat would be like that of a furnace, but it would interpose a measure of protection which would effectually check a fire in its initial stages, and prevent the sudden flashing into a blaze, through this channel, of all the floors at a time of a great store or warehouse. This is a precaution which may be taken with so little trouble and expense that it is worth the consideration of every owner or occupant of a building where the elevator shaft is of the old style of combustible construction.

The Lost Rivers of Idaho.

One of the most singular features in the scenery of the Territory of Idaho is the occurrence of dark, rocky chasms, into which large streams and creeks suddenly disappear and are never more seen. These fissures are old lava channels produced by the outside of the molten mass cooling and forming a tube, which, on the fiery stream becoming exhausted, has been left empty, while the roof of the lava duct, having at some point fallen in, presents there the opening into which the river plunges and is lost. At one place along the banks of the Snake, one of these rivers reappears, gushing from a cleft high up in the basaltic walls, where it leaps, a cataract, into the torrent below.

Where this stream has its origin, or at what point it is swallowed up, is utterly unknown, though it is believed that its sources are a long way up in the north country. Besides becoming the channels of living streams, these lava conduits are frequently found impacted with ice masses which never entirely melt.

A Brick Tenement House.

San Francisco can justly be termed blessed in not having within its limits a brick tenement house; but as we have received repeated inquiries for a house of this description, that could be erected in the "fire limits" and not conflict with the "fire ordinances," we present the accompanying elevation and plans of a building suitable to those who desire to live in "flats" and yet reside in the business portion of the city. They were prepared expressly for this Journal by W. Claude Frederick, Architect.

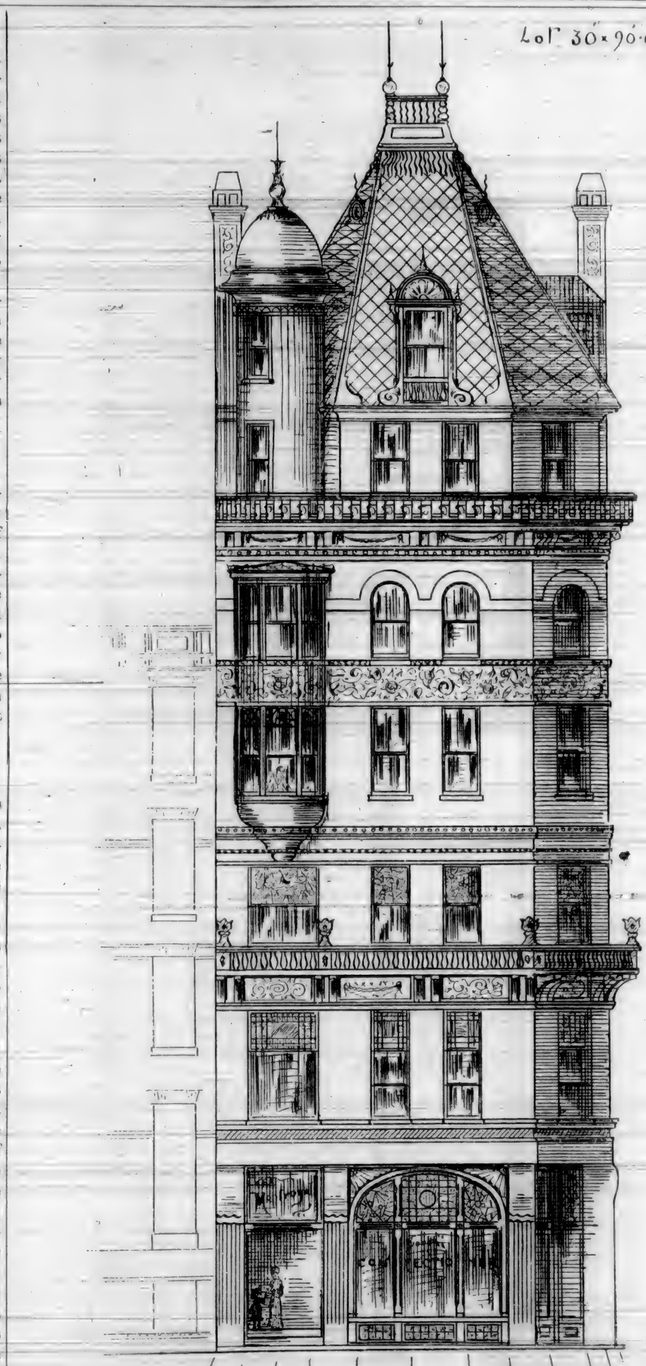
The elevation, though striking and presenting many features not usually found in San Francisco architecture, is not an expensive one; the arrangement of the rooms is clearly shown by the engravings and will well repay a careful study. Each floor above the first is a duplicate of that presented on page 87.

To Prevent Scratching Matches on Paint.

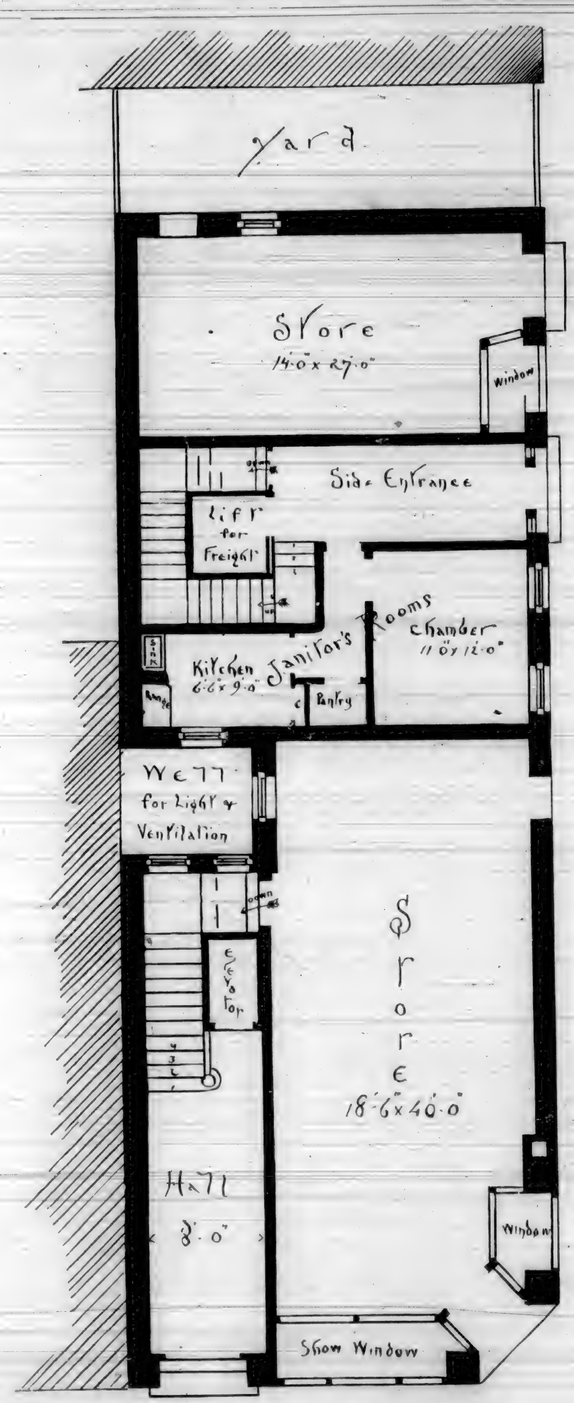
A correspondent, in Florida, of *New Remedies*, speaking of the defacement of paint by the inadvertent or heedless scratching of matches, says that he has observed that when one mark has been made, others follow rapidly. To effectually prevent this, rub the spot with flannel saturated with any liquid vaseline. "After that, people may try to strike their matches there as much as they like, they will neither get a light nor injure the paint," and, most singular, the petroleum causes the existing mark to disappear, at least when it occurs on dark paint.

How Carpet Tacks are Made.

The iron is received from the rolling mills in sheets from 3 in. to 12 in. wide, and from 3 ft. to 9ft. in length, the thickness varying, according to the kind of work into which it is to be made, from ¼th to 1-32nd of an inch. These sheets are all cut in about 30 in. pieces and, by immersion in acid, cleaned of the hard outside flinty scale. They are then chopped into strips of a width corresponding to the length of the nail or tack required. Supposing the tack to be cut is an 8-oz. carpet tack, the strip of the iron, as chopped and ready for the machine, would be about 11-16ths of an inch wide and 30 in. long. This piece is placed firmly in the feeding apparatus, and by this arrangement carried between the knives of the machine. At each revolution of the balance-wheel the knives cut off a small piece from the end of this plate. The piece cut off is pointed at one end, and square for forming the head at the other. It is then carried between two dies by the action of the knives, and these dies, coming together, form the body of the tack under the head. Enough of the iron projects beyond the face of the dies to form the head, and while held firmly by them, a lever strikes this projecting piece into a round head. This, as we have said before, is all done during one revolution of the wheel, and the knives, as soon as the tack drops from the machine, are ready to cut off another piece.



Elevation of Brick Tenement House.—W. Claude Frederick, Architect.



First Floor Plan of Brick Tenement House.

Architectural Competitions.

THE subject of competitive plan making, which, in nearly all cases, means obtaining men's services without an equivalent, is being very freely ventilated and discussed in all journals and publications issued in architectural interests, throughout America, England and other countries, with ninety-nine per cent. of all that has more recently appeared in print, strongly condemnatory and in opposition to the methods practiced, under the delusive and misleading pretext of competition, by which State, county, and municipal governments, corporate institutions, associations, and sometimes private individuals obtain and secure the results of the labor, skill and coin of architects without compensation.

The many wrongs inflicted upon the profession as a whole, and upon its more worthy and competent members individually, through the *modus operandi* of competitions, have grown to such magnitude, and become so unmistakably the means through which gross injustice in nearly all cases is practiced, that the feeling and sentiment among the more intelligent and honorable in the profession is decidedly and emphatically opposed to the disreputable method of competitions as practiced—particularly during the past decade.

Some, and by far too many of the "Set up's" have been shrewdly-managed affairs, so disguised by finely-worded conditions and pretenses as to deceive and mislead silly men in the profession, into an expenditure of effort, time, labor and expense, while, in fact, the chances of success have been ninety-five per cent. in favor of some certain party enjoying the decidedly large prestige of being the *party preferred* by those managing affairs.

In England, a movement is on foot under the auspices of the Royal Ins itute of British Architects, the object of which is to obtain the signatures of *all practitioners* of creditable repute, pledging themselves not to participate in any competition not subject to the arbitrament of disinterested professionals, recognized as qualified to adjudge the intrinsic merits of the plans submitted, and enjoying a good reputation as to moral integrity.

We are right glad to learn that the architects of England have taken so decided a stand in the matter, and only regret that the profession in our own country is so overrun with pretenders and men of mediocre professional abilities that it would be folly exemplified to express the hope that a reform in professional practices, as far as competitions are concerned, is among the reasonably near probabilities.

But this the respectable architects in California can do, especially members of the chapter,—refuse to participate in any competition, not conditioned exactly as provided in the constitution and by-laws of the organization, and such other regulations as may at any time be adopted by the local or parent chapter.

Bound Volumes California Architect, $2.50

Modifying the Proportions of a Room.

TO MAKE a room appear higher, the plane surface of the ceiling should be decreased by the mouldings of the cornice, by panels, or, in the absence of these, by bands of color performing the same office. A vertical system of line should be adopted in mural decoration, and the mantel should be lower.

To make a room appear lower, exactly the opposite treatment should be adopted; that is, to increase the plane ceiling, adopt a horizontal system of mural decoration, with a dado and a high mantel.

To make a room appear wider, is accomplished, to a certain extent, by making it appear lower; but where this is undesirable, or where it is insufficient, the effect can be reached by adopting a mural decoration on a graduated scale of form, decreasing upward, so that two or more patterns at the top similar to those at the foot are found to occupy the same space as one at the foot, and this effect can be much increased by a gradation of color upward from dark to light.

To make a room appear narrower is accomplished, to a certain extent, by making it appear higher; but where this is undesirable or insufficient, the effect can be obtained by adopting a strongly-drawn large pattern in strong color for mural decoration.

To make a room appear longer is to an extent accomplished by making it appear lower and narrower; but where these are undesirable or insufficient, the effect may be obtained by decreasing the scale and strength of color of the mural decoration adopted at the ends.

To make a room appear shorter is accomplished, to an extent, by making it appear wider and higher; but the effect can be achieved by increasing the scale and strength of color of the mural decoration adopted at the ends.

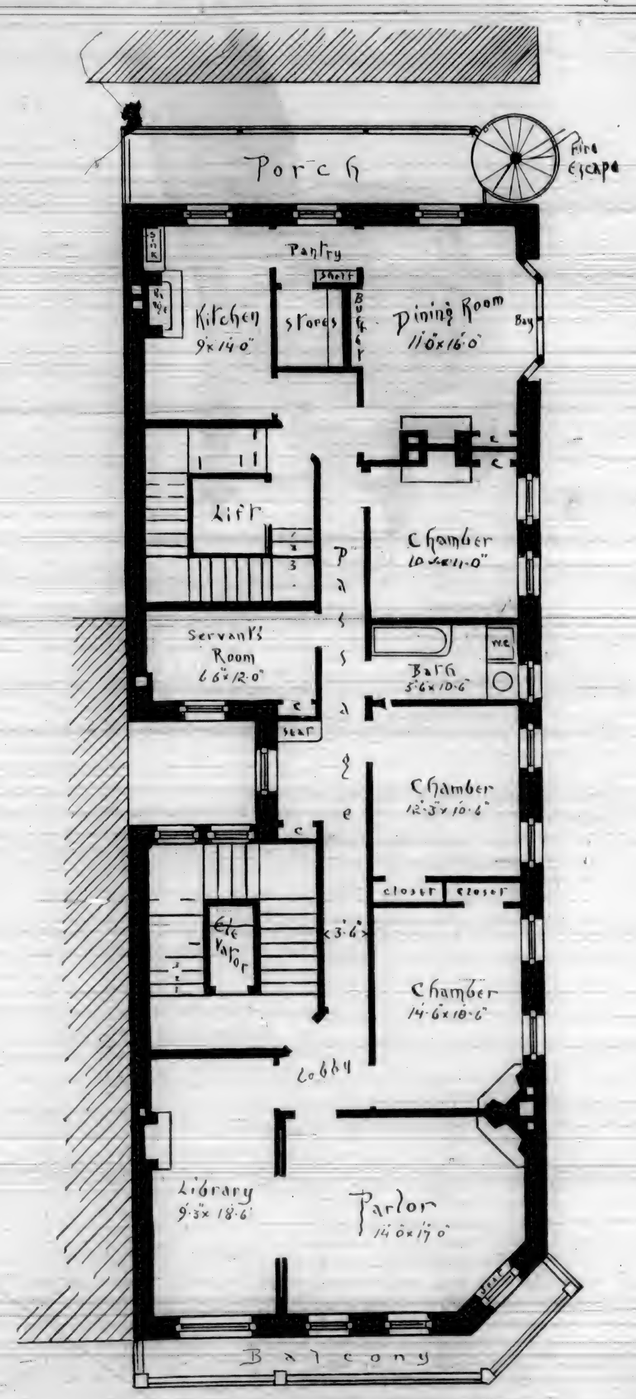
Any of these effects can be modified or increased by the treatment of the floor surface, whether by carpets, rugs, painted boards, or by parquet flooring, lines running across a room, or rugs laid down at intervals, having the effect of shortening, and consequently to an extent of heightening and widening a room. Lines running in the length increase this dimension, and to an extent reduce the height and width. A polished floor increases the apparent height of an apartment by reflecting all vertical lines and prolonging them.

"HISTORY OF ARCHITECTURE in all Countries from the Earliest Times to the Present Day." By Jas. Furguson.

This work is one that should be in the possession of every architect. Especially should students and draughtsmen secure a copy. Being a reprint of the London edition, the price has been materially reduced. Two large volumes, containing over 1,200 pages, beautifully illustrated. Price, complete, $15.00.

"BUILDING SUPERINTENDENCE."

This new work is of invaluable assistance to the architect and builder. It is written by a gentleman long connected with the architectural profession, and is eminently practical in its character. We will send a copy to any address upon receipt of $4.00.



Second Story Plan of Brick Tenement House.

DESIGN FOR CHAIR.

The Pyramids.

WHY the pryamids were built is a question which has puzzled antiquarians and savants for centuries. The theory of John Taylor was that the pyramids were erected by kings who had conquered and were detested by the Egyptians, and that while the tradition of injustice in making them labor on such stupendous piles lingered on through after history, the purpose and meaning of the kings and their architects had been forgotten. Taylor believed that the Great Pyramid was designed to record in its proportions and its interior features, certain important truths of religion and science, which were not for the people then living, but for men who were to come 4,000 years or so after. And this view has been accepted by Prof. Piazzi Smith, Astronomer Royal, of Scotland, whose writings have attracted a great deal of deserved attention.

But R. A. Proctor, the most popular living writer on scientific subjects, combats this theory with a great deal of learning and plausibility, in a work on "The Great Pyramid," published by R. Worthington. He maintains that the structure was essentially astronomical and astrological—the two were then virtually one—and that no explanation which does not take this element into the account can explain facts. There are many pyramids, and each belongs to a separate king; we are forced to believe that there was some special relation between the pyramid and its builder, seeing that each king wanted a pyramid of his own. The theory that they were tombs receives only a partial support, and would not account for the most important features discovered in their peculiar architecture.

Without exception, the pyramids are built on special astronomical principles. Their square bases are built so as to have two sides lying north and south. "One can imagine no reason why a tomb should have such a position," writes Mr. Proctor; and he says: "It is not easy to understand why any building at all, except an astronomical observatory, should have such a position." And he elaborates an ingenious theory which fits remarkably well as it goes, why these wonderful structures were built as we find them.

Each king had his pyramid, and each had his horoscope cast. A succeeding king could not use the pyramid of his predecessor; it was closed up and abandoned and a new observatory begun. But no explanation yet made has rendered it at all clear to the practical modern mind why the ancient kings exhausted their subjects with the labors that were necessary to the raising of these massive mountains of stone and brick. Mr. Proctor admits that there are difficulties in the astrological theory, but they arise from our inability to understand how men ever had such fullness of faith in astrology as to devote enormous sums and many years of labor to the pursuit of astrological researches. Besides the essay on the "Great Pyramid," this volume contains short papers on the origin of the week, Saturn, and the Sabbath of the Jews, astronomy, and the Jewish festivals. The volume is rich in ingenious materials and scientific information.—

STAINED GLASS WINDOWS.

MESSRS. G. W. CLARK & CO., 645 and 647 Market Street, have on exhibition the most beautiful and artistic designs that have as yet been shown to our people, for stained glass windows. They have secured the agency of the La Farge Decorative Art Company, and are fully prepared to furnish *stained glass work* of every description and in a great variety of designs. Messrs. Clark & Co., are also agents for *Linerusta Walton*, the most beautiful material yet invented for decorative purposes.

A French Class.

Under the Auspices of the S. F. Chapter.

DURING the past month, a class in French has been organized, principally intended for Architects and students connected with the Chapter. Any one, however, can join. The terms have been placed especially low for the purpose of inducing many of the younger members of the profession, and those interested in art, to join the class.

The class will be under the direction of Madame Pietro Mezzari, a lady well known in artistic circles. The class meets every Friday evening. Parties wishing to join will please send their names and address to this office.

Books and Special Notices.

GOODELL & WATERS, of Philadelphia, have sent us their Illustrated Catalogue of Wood Working Machinery. It contains numerous engravings of every kind of machinery used for wood working purposes. We would advise those desiring to purchase anything in their line to address a note to the above firm.

THOS. KANE & CO., of Chicago, have forwarded to us a specimen sample of their wood carpeting, which we will be pleased to show to callers.

FOUNDATIONS AND "FOUNDATION WALLS" for all classes of buildings, pile driving, building stones and bricks, pier and wall construction, mortars, limes, cements, concretes, stucco, etc. Practical explanation of the various methods of building foundation walls for all kinds of buildings. Revised and enlarged edition. A copy of this work will be sent free of postage to any part of the world upon receipt of the Publisher's price, $2.00.

WE have received two new works by Wm. Paul Gerhard, entitled "Sanitary Drainage of Tenement Houses," and "House Drainage." This writer is well known as one of the most experienced, and best qualified of the sanitary experts of the present age. A copy of these works should be in the possession of every house owner, and their contents thoroughly studied.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market st., S. F.

FOR WEEK ENDING APRIL 29, 1884.

297,657.—CULTIVATOR—Daniel Archer, Madison, Cal.

297,910.—TRACK CLEARER—Ephraim B. Bishop, San Francisco, Cal.

297,664.—MITER BOX—William L. Bovyer, San Francisco, Cal.

297,668.—TOBACCO SWEATER—George Brownstein, San Francisco, Cal.

297,594.—STRAW CARRIER FOR THRESHING MACHINES—Maximilian J. Grssner, San Francisco, Cal.

297,796.—CARTRIDGE IMPLEMENT—Henry T. Hazard, Los Angeles, Cal.

297,698.—SAW SWAGE—Simon Kinney, San Francisco, Cal.

297,699.—PIN FOR ELECTRIC INSULATORS—John M. Klein, San Francisco, Cal.

297,714.—VEHICLE—Jacob Price, San Leandro, Cal.

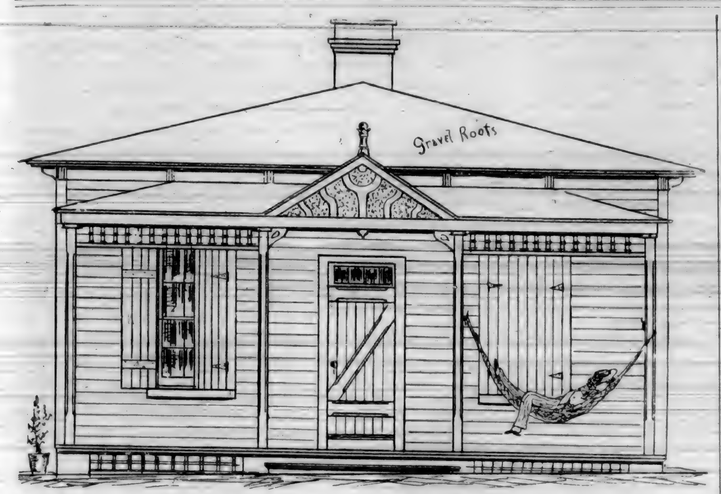
297,857.—FIRE ESCAPE—George Sinfield, Portland, Oregon.

297,647.—SUBMARINE VESSEL—Josiah H. L. Tuck, San Francisco, Cal.

297,648.—MARINE TORPEDO—Josiah H. L. Tuck, San Francisco, Cal.

297,734.—WHIFFLETREE—James Whitcomb, San Jose, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.



DESIGN FOR A SUMMER RESORT COTTAGE.

A Summer Resort Cottage.

THE accompanying illustrations represent a design for a comfortably arranged cottage to be built at a seaside or summer resort. Economy, with ample accommodations, are the main features. All the partitions are made of inch boards. The front is covered with rustic, which may be extended around the building, depending altogether upon the amount of money one wishes to expend. The rooms are very convenient and large enough for the purposes intended. The dining hall, with its cheerful fireplace, may also be used for a general meeting room in the evening.

The plan is admirably adapted for places like Pacific Grove and was prepared especially for the consideration of parties desiring to locate in that beautiful place.

We are indebted for the plans to W. Claude Frederick, Architect.

Album of Mantels.

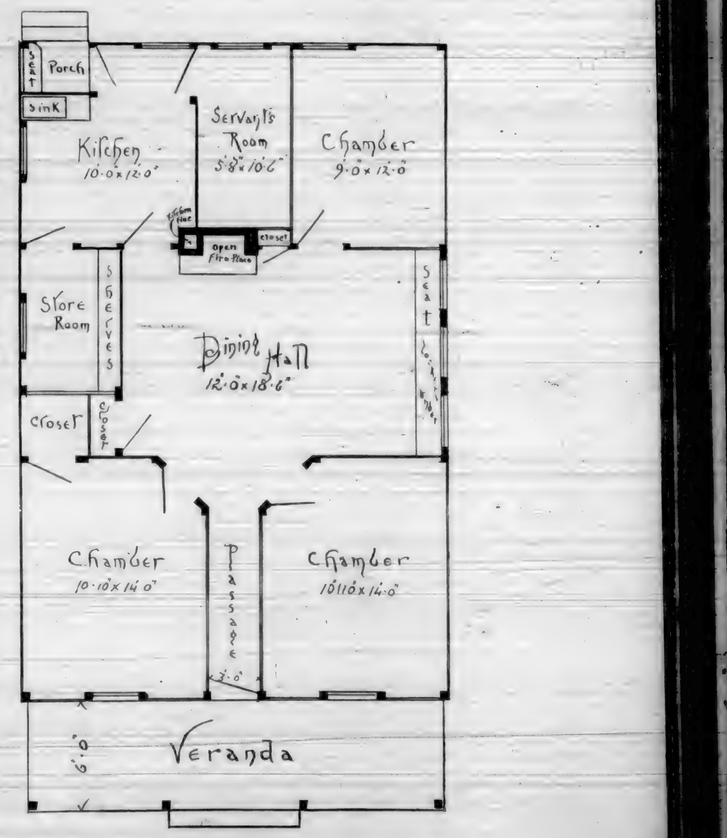
A NEW work, containing designs for every description of mantels. Price, $8.00.

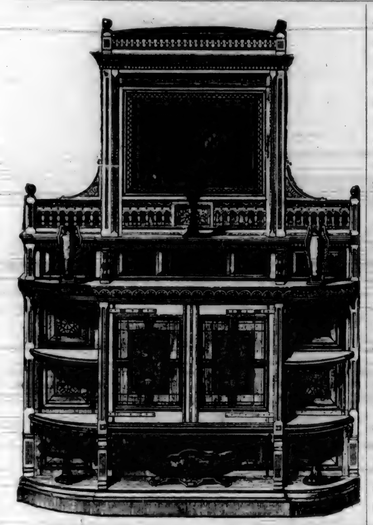
Work—for a Home.

THERE are two important steps to be taken by every young man who has to depend upon his own exertions for a living. The first is to master some occupation which he can rely upon in after life for a livelihood. The three or four years spent in learning a trade are to most young men years of privation, during which they are compelled to exercise the most rigid economy. The lessons taught during these years, if properly applied, will render the next step—the procurement of a home—comparatively easy of accomplishment. A wage worker, in the possession of a good trade and a comfortable house to live in, is on the highway to competency.

The greatest obstacle to the steady advancement and prosperity of the mechanic is the constant drain which the landlord makes upon his income. It is plain, therefore, that the first step toward independence is for the mechanic to own his own house. If he has to pay out in rents every ten years as much money as would secure for him a comfortable home, there is but a slim chance of his ever accumulating much money. Once a wage worker becomes his own landlord, he can save a sum annually at least equal to what his rent would be, and this continued for a period of years must result in a competency if a judicious use is made of the money. It may not be possible for all mechanics to obtain homes of their own, but thousands who continue to be renters all their lives could do so if they would only make an effort. It requires some degree of self-denial to accomplish the result, but once obtained it removes the chief obstacle to those steady accumulations which are the foundations of all fortunes, great and small.

Detail Cottage and Constructive Architecture, Price $10.00.





HANDSOME DESIGN FOR A CABINET.

Unhealthy.

[Special Eastern Correspondence of the CALIFORNIA ARCHITECT.]

IN a series of articles prepared from actual laboratory stata, we shall strive to show plainly, first, the wanton ignorance in the home; second, the superfluity of physicians and their gross inefficiency; and, lastly, the comparatively few occupants of graves who were not murderers or suicides, perhaps both. In making these tests, and in the preparation and presentation of resulting facts, we have only consulted what the spectroscope, microscope, chemistry, and physical laws have revealed, having no desire to array ourself in an antagonistic manner with any trade or profession in life. To the contrary, we take this manner of inviting the co-operation of all; in order that, when completed, it may be truly said of them, 'tis finished, and wiser are we.

Late in the autumn of 1883, one of the most beautiful and enterprising cities on the Ohio River found itself in the embrace of an epidemic, the nature of which baffled all available medical talent. Expert architects and engineers were unable to agree concerning its cause, but unanimously urged a rigorous cleaning up and thorough fumigation of all the infected wards which comprised the most popular and aristocratic in the city, but all of no avail. The disease spread, carrying death before it, until scarcely a house in the entire square but wept over the vacant chair. To be sure the physicians all theorized, nevertheless they failed to arrest its progress.

When the epidemic had begun to subside, the municipal authorities seemed to have awakened from their lethargy and set about investigating, manifesting a willingness to assist, financially, all who reached results that appeared reasonable. Of course chemists were on hand in numbers with their appliances for examining liquids, gases and solids as a means of reaching some conclusion. The water supply furnished from a rapidly running stream by the Holly system was found good and pure in the ordinary acceptation of the term, but a close inquiry revealed the fact that localities the most afflicted with the epidemic—a sort of low form of typhus fever—were supplied largely from private sources. These being analyzed, unmistakable evidences of uric acid and dumb bell crystals were found, though the wells were well kept, free from filth, and far removed from all apparent opportunities for contamination, still this extraneous matter was present and necessarily had an origin somewhere.

Before proceeding farther, it will be best to describe the situation of the place. The city is situated on a very high point, built substantially, mostly of brick and stone. In or near the center is the Court House and public park, occupying an entire square, which is surrounded by a beautiful and high iron fence, between which and the street is a stone pavement, it being, as it were, fenced in with heavy railing, to which the farmers, traders, hucksters, etc., fastened and fed their teams, which at the time of our first visit, was lined closely all the way round with a medley of teams. The gutter, substantially laid with granite and cement, made perfect drainage for all liquids deposited, while once or twice per week the jailor and the prisoners scraped all solids, etc., and washed them down the gutter, which conducted them to the river, below the filter from which the city's water supply is obtained. Apparently, here was a perfect system of drainage, for where the surface drain or gutter entered the river, the stream contained high banks and run in the form of a current, the city occupying the inner or concave side. We have been thus explicit in our description that all may appreciate fully the situation to be discussed further on.

In the spring preceding the outbreak of the epidemic, the county had given the contract for erecting a bridge across the river at the lower end of town, and the city awarded the contractor the privilege of making coffer-dams for laying pier foundations, but to make the expense of hauling stone, iron and all heavy material less, this contractor made a dam from the inner shore, nearly three-fourths across the stream. On the top of this was a roadway or pike.

By tracing carefully, by the aid of microscopic chemistry, we found that the dam had furnished a different current for the river, and all along the right bank the water was stationary above where the gutter from the square had a termination. A large factory had been erected on a low, marshy tract adjacent, and procured its water supply from shallow driven wells. This tended to drain off the stagnant water, when this backwater from the river found ample space to accommodate the slightest raise.

From this low section the water gradually seeped and eventually found its way into the wells, the water from which poisoned scores. Thus we found direct communication well established between the Augean Stables at the square of the Court House to the wells of the citizens.

(To be Continued.)

Painting

PAINTING is one of the many things that an architect is expected by his client to be thoroughly posted on, and certainly for his own comfort he should be. Yet how many architects are there who understand the matter? It is easy enough to specify "two-coat" or "three-coat" work, and to remember what parts of the building it is best to have treated in one way or the o her; and to superintend the painting, so far as to make sure that wood is primed only when thoroughly dry; that it is properly rubbed down and filled is also comparatively easy, but to superintend the mixing of the paints, to be able to detect and condemn inferior and adulterated oils, to be sure that the lead is not mainly barytes, to be able to take the paddle yourself, and by a real knowledge of the properties of pigments to mix a tint that you desire to obtain, to know what of the many brands of "ready-made" paint it is allowable to use,—these are attainments that the architect rarely has. Yet he should have them. He should know what varnishes will crawl and crack, and what will stand; he should know about stains, about wax and oil polishes, metallic paints, shellac, and the infinite variety of pigments. And we believe that some day he will find it well for him to know these things with a scientific if not a practical knowledge, and not leave them as now entirely to the honesty and intelligence of the painter's foreman, just as now he knows more about plumbing than the architect of ten years ago ever dreamed of knowing.—*Am. Architect and Builder.*

SAWDUST, as an ingredient of mortar for house plastering, is commanding considerable attention in certain directions. It is used in place of sand. It is claimed that such mortar is more porous than the ordinary kind, consequently the face of a wall composed of it is warmer; that it is a non-conductor of sound and dampness; that it overcomes the echo in churches and halls. In the manufacture of the mortar a glutinous substance is used, which sticks it firmly to the wall.—*The Lumberman.*

SACK'S AUTOMATIC SELF-DISCHARGING WATER CLOSET.

WE would call particular attention to this New Water Closet, now being introduced in this city by Mr. Wm. E. Stevens. Its merits are fully set forth in his statement and card on Page IX, to which we will refer those interested. It is the *only self-discharging* closet now in the market, and its simplicity and non-liability to get out of repair, warrant its general adoption by every architect, property owner, plumber, etc. They can be seen in successful operation at Mr. Steven's place of business, Market cor. Larkin.

Steel Square and its Uses.... ..... **$1.00**

John M. Curtis.

GENERALLY those who are most successful in this world are the ones that, being left alone in the very early stages of life, with no parents to watch and guide their course, yet struggle manfully along, and develop the talents given to them by the Great Architect above.

Mr Curtis was left an orphan when very young, and his guardianship was assumed by Wm. T. Coleman, of this city; to this gentleman does he owe much of his success as a builder, and, later, as an architect. The principles instilled by Mr. Coleman into Mr. Curtis' mind, were those that taught the man to be independent and to take care of one's self by persevering industry and thus earning success.

Early manifesting an inclination to handling carpenter's tools, Mr. C. was apprenticed with Messrs. Burt & Son, of St. Louis, at that time one of the prominent contracting firms of that city. Upon the completion of his articled time, he entered the office of Mitchell & Brady, architects, in the same place, and remained over five years in their employ.

California presenting unusual inducements to men of energy, Mr. Curtis started for San Francisco; shortly after his arrival, he was employed by E. J. Baldwin as assistant architect of his magnificent hotel and theater, remaining in that capacity until the entire building was finished.

Feeling that a more extended *practical* knowledge of carpentry was necessary in order to thoroughly master all the intricacies of his future profession, Mr. Curtis again entered the lists of contractors in this city. Several fine dwellings were built under his direction, some of which were under the immediate superintendence of the senior editor of this journal.

JOHN M. CURTIS.

After an extensive experience in the building line, we find Mr. Curtis again resuming his practice as a professional architect. Among his first clients, was his former guardian, whose offices he designed, and which are among the nicest fitted up in the State. All the principal street decorations used during the Triennial Conclave, were d signed and erected under the supervision of Mr. Curtis.

Business increasing, Mr. Curtis associated himself with A. A. Bennett, and located his offices in the German Bank Building, 528 California Street. These gentlemen have now under construction the Sonoma County Court House, at Santa Rosa, the Humboldt County Court House, at Eureka, the University of Southern California, at Los Angeles, and several private dwellings.

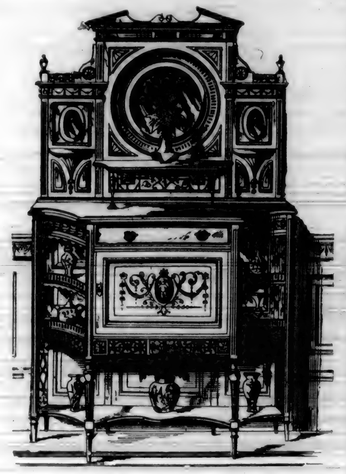
Mr. Curtis is also, at present, supervising architect of the new City Hall. He is a member of the S. F. Chapter American Institute of Architects and is prominently identified with several Fraternal Associations.

The Liability of Contractors.

A RECENT decision of the Supreme Court of Nebraska is of special interest to builders. S sued B for $492.60, the balance due him for building a two-story brick house, and B made a counter claim for defective material thrown out and money expended in repairing the unskillful work of S. The contract price was $2,535, and the plaintiff paid $2,042.40; the counter claim was $1,985, for which the defendant got judgment. The defense to the counter claim was a most novel one, viz.: that the defendant had "no experience in laying foundations, as the defendants knew." The case, Sherman *vs.* Bates, was carried to the Supreme Court, where the judgment was affirmed. Judge Maxwell, in the opinion, said: "A party entering into a contract to construct a building thereby agrees that all parts of the structure shall be put up according to the agreement. As a defense to inferior workmanship, he cannot say: 'I am not a mason, or carpenter, or tinsmith; therefore I am not liable for defects caused by unskillful or careless workmen.' The question is not one of skill on the part of the contractor, but of compliance with the contract." If a contractor agrees to erect a building in a certain manner, he must comply with the agreement, and no plea of a lack of skill, of himself or any of his workmen or sub-contractors, will constitute a defense for a failure to comply with the contract.—*Building.*

Gas Leakages.

AN indicator of gas leakages has been constructed by Mons. C. V. Jhan, and is described in the *Revue Industrielle*. The apparatus consists of a vessel of porous earthenware, such as the porous cell of a galvanic battery, set upside down, and closed by a perforated India rubber stopper. Through the hole in the stopper, the inside of the vessel is connected with a pressure gauge containing a little colored water. The vessel can be exposed to the air of an apartment where a leak of gas is suspected; or a sample of the air may be contained in a bell glass inverted over the porous cell. The diffusion of gas through the earthenware raises the level of the water in the pressure gauge; and when the latter is properly graduated and proportioned to the capacity of the cell, exact and delicate indications may be obtained in a simple manner. This species of diffusiometer is so sensitive that when an Argand burner is gradually turned down until it is extinguished, the instrument, if held above the burner, will show a considerable rise of the water in four or five seconds. If held over an ordinary burner, turned on just sufficiently to be ignited, the liquid rises very rapidly. When the instrument is graduated in millimeters, a volume of one-half per cent. of gas in a room may be distinguished by it. An example is afforded by a case of sickness, which, in the opinion of the medical attendant, was due to gas poisoning. Some doubt arose on the point, because gas was not laid on to the house. The diffusiometer was brought into requisition, and showed the presence of gas, the source of which was afterward found in a broken main three meters distant from the house. A modification of the same instrument is made, whereby the sensitive portion is adapted for permanent exposure in any place difficult of access—such as the ceiling of a theater or public building, where gas might be expected to collect, the indicating portion being fixed anywhere within view.



NEW DESIGN FOR CABINET.

The Reliability of Ready Mixed Paints.

THE question of the reliability or durability of ready mixed paints continues to be one of the most interesting and perplexing ones connected with the trade. Shall the oft-repeated statement, "Ready prepared paints are not to be depended upon with that degree of certainty which good work demands," be taken as an accepted truth, not admi ting discussion, or, on the other hand, shall the decision be reached that there are honest, ready-prepared colors, and that the question of the responsibility of the manufacturer sh uld determine where they be purchased?

The value or durabici y of a color depends upon the vehicles used in mixing the paints, and when, through downright dishonesty, or the demands of a too strong competition, artificial pigments are used, an unreliable product is the result, and the prejudice existing among so large a class of painters against the use of ready-mixed paints is strenthened. When this is so strong that it is almost impossible to induce painters to make use of ready-mixed paints at all, surely it must be conceded that there are some good reasons back of this prejudice.

One old painter says: "I have always and still entertain prejudice against the mass of ready-mixed colors and paints turned out by grinders and manufacturers. My objections are that we cannot safely rely upon their quality or even the honesty with which they are compounded—so many different substances are called by the same name. We find ochres, for instance, in the market, which have little, if any, of the natural pigments in them; many of them are artificial products. The same with umbers, carmines, vermilion, in fact, with nearly all our colors and pigments that it will pay to imitate."

A strong argument many painters bring forward in favor of mixing their paints is that these imitations and frauds can more readily be detected in the crude materials than in the prepared paint or color. While this is true, it is also the fact that the painter who mixes and grinds his own colors can very easily be, and very frequently is, imposed upon by adulterations, artificial pigments, etc.

It is an admitted fact among the best class of painters that where the skill and honesty of the large manufacturer can be relied upon, the latter can better secure uniformity of quality and color. Experts in the mixing and application of paints—men thoroughly understanding the chemical relations of the colors being handled and with a large amount of material to select from—must certainly be able to secure a more uniform result, both as to quality and tone of color, than the ordinary painter in his shop, with few facilities for the work on hand, and a limited stock from which to select.

Again, a greater degree of durability can be obtained by the large manufacturer who is at the same time honest in his manipulations. The permanence of colors in secondary or mixed paints depends primarily in the chemical relations of the colors and pigments employed. These secondary or mixed colors are produced by various combinations, and the rule is to use the least number of colors possible to secure the desired tint. Where the greatest skill is displayed in these chemical manipulations, and where there is the widest choice of material, naturally seem to be the place where the greatest durability in the mixed paint could be secured.

Then there is the question of economy. Granted the honesty of the large manufacturer, with his superior facilities, advantages for purchasing the crude material, etc., is it not reasonable that the cost of manufacture should be much lower than where the opposite is the case? The large manufacturer buys his own materials and thus becomes responsible for their quality, while the painter mixes and combines materials purchased by another party, and the quality of which material he is ignorant of, except so far as a careful examination and his own chemical knowledge go to inform him.

The whole question seems to us to resolve itself down to this: Those who purchase only standard ready-mixed paints manufactured by well-known and responsible concerns, will get honest goods, and those who pursue the opposite course will get the adulterated and fraudulent goods. While there are unprincipled manufacturers, it is not really a difficult matter to find the reliable and honest ones. A good reputation for honestly-compounded paints and colors is built upon a solid foundation, and is not recklessly hazarded by the fortunate possessor. Even the severest competition of his dishonest rivals who undersell him, and promise just as good or better goods than he manufactures, will not drive him into the compounding of adulterated goods.—*The Painter.*

The Trade in Modern Antiquities.

ONE of the chief delights of Continental travel, as every person of experience will admit, is the unlimited opportunities it affords for buying antiquities. The statuary, the coins, and pictures that may be purchased in Italy are a source of never failing interest to English travelers and of never failing profit to Italian dealers. Andalusia, again, is a huge curiosity shop. Being once upon a time in Seville, we came across a retired British grocer, or tailor, or something of that kind, who had just purchased a "Madonna and Child"—unhappily, unsigned—which he had picked up for a few pounds in a dingy back street. He was going to send it to the Exhibition of Old Masters, and, if he ever did so, he probably found that it was worth only a pound or thirty shillings at the outside. It is the same, indeed, throughout Spain.

The altar cloths, the broken fans, the inlaid tables and cabinets, as resplendent as anything in the convent of the Cartuffe at Granada, the wonderful chairs and the still more extraordinary scraps of ancient lace, upon which all who have ever traveled in Spain have spent much money—these abound from Malaga to Irun, and naturally one is inclined to speculate a little on the odd circumstance that the supply is more abundant than ever, although the demand is fairly brisk.

Tangiers is, we should say, a hotbed of modern antiquities, and even Mr. Chamberlain bought some of them when he was over there a year or so ago. He ought to have known something about this class of goods, being a Birmingham man, but the childlike faith of the president of the Board of Trade in all things ancient is notorious. America, oddly enough, has taken to this business of manufacturing the antique Dutch cabinets, that, with bronze panels, dingy and marked with the cracks of fictitious centuries, are turned out every day from Chicago furniture stores, and for some purposes they are quite as useful as if they had indeed belonged to some departed burgher in the dead cities of the Zuyder-Zee.

New York experts in this sort of forgery make a specialty of Queen Anne chairs and tables, and the imitation is so perfect as to deceive all but those who have studied such things minutely in Europe. The explorer of furniture stores may come upon magnificent specimens of English Gothic chamber pieces, or ancient-looking Chippendale and Sheraton chairs, which might have belonged to Queen Elizabeth but for the fact that they did not.

It must be puzzling at first to discover in New York shops stamped leather chairs of the time of Louis Treize, plentifully ornamented with brass nails, whose heads are fully an inch in diameter, and the citizens of that enterprising city are invited to become the happy possessors of as many of these treasures as they like on ridiculously low terms. If, however, the explorer is inquisitive, and the furniture venders are in a tolerably can-

did mood, the visitor may be conducted into some back yard where these gems of high art are produced.

A Queen Anne's chair, just made, can, for instance, be supplied with worm holes by the simple process of tilting it bottom-side up and firing a charge of pigeon shot into the bottom and front of the seat.

Old armor, too, is a good line in this business, the drawings required for the purpose being made from the collection in the Grand Opera House, in Paris. It is said that Birmingham knows something about this branch of the trade, and that helmets, shields, casques, breastplates, and complete suits of mail are regularly manufactured for the gratification of credulous oil speculators and retired pill manufacturers. If a man starts a lot of ancestors he likes to have dummies of them in his hall rigged in their medieval iron-mongery. If Birmingham did not gratify him, Germany would.

It is astonishing how many tons of antiquites are annually sold along the Rhine, and it is even asserted that in Castle Colburg, where Martin Luther threw his inkstand at the devil—and unhappily missed him—the original splash was cut up and sold long ago; but that as the timber is massive, the place is carefully re-inked every night for the purpose of sale the next day. We cannot say how much truth or falsehood there may be in this particular story. There might have been some excitement in seeing the original transaction if both the distinguished parties to it were present. There can be none in gazing on a patch of ink. The trade in modern antiquities, however, is a curious reality, as real as the sale of old clothes or tombstones. It is a fact calculated to weaken one's faith in life.—*Ex.*

Color.

TO THE house painter who is ruled largely by the restrictions of a customer as to choice of colors and quality of material, and, it may be, by prevailing customs of decoration also, the study of color does not seem a great necessity. To put paint of some sort where it will prevent decay has been his chief duty; what the color was, or what the effect it would produce, seemed less important.

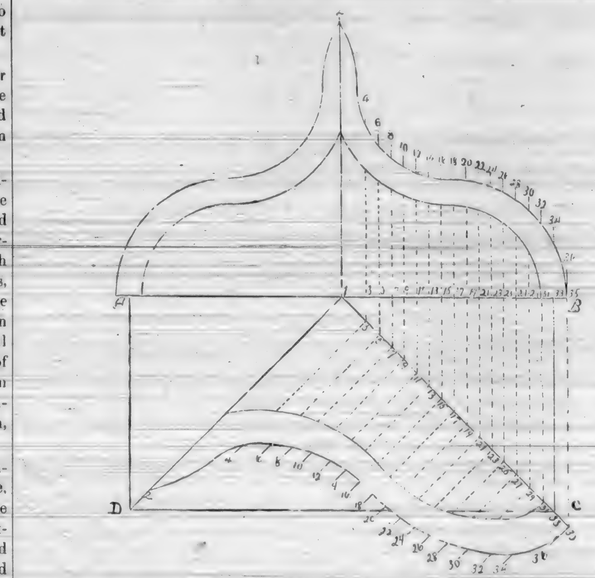
In the calling of the painter, aside from its conventionalities and bread-earning purposes, there is an ample field for his genius, if he have it, or for any talent he may possess. Between black, the one extreme of color, and white, its other extreme, there is a long stretch of varied and beautiful landscape, which can be made more beautiful by careful cultivation, or uglier by neglect and distortion. In order to its proper cultivation, the painter must acquaint himself with the qualities of color, the variations to which it is susceptible, its expressive power, and its proper relationships by harmony and contrast.

That color can speak to the artistic eye is a fact well known. That it too often tells a tale of the ill treatment to which it has been subjected quite as pitiful, and probably more truthful, than the street beggar, is also true, and that under skillful manipulation it reveals its power, unequaled to charm and to instruct, is beyond question.

What variations lie between black and white, and what the proper relations of these variations are, nature teaches; for they all are found in the golden glory of the sunset, in the somberness and majesty of the storm, in the endless variety and beauty of vegetation, in the grey, purple and brown of rock, hill and mountain, and in the soft tint of untainted water. Watch the play of light in nature's work, drink copiously at this unfailing source of knowledge, and lessons in the use of color may be learned which will greatly improve present tastes with regard to decoration.

The expressiveness, the sympathy, the contrasting beauty which can be got out of color for house decoration, should be drawn out by the painter and applied so that none of our buildings would be ugly in appearance, or inharmonious with surroundings. Study and persevering practice will accomplish this, and it will prove a source of intellectual and pecuniary profit to those who become masters of the art.—*The Painter.*

GAS FITTERS' CEMENT.—Melt together four and one-half parts of resin (by weight), one part beeswax, then stir in three parts of Venetian Red, and pour into moulds made of oiled paper, or cold iron moulds.



RULE APPLYING TO THE CURVED RIBS OF BAY WINDOWS.

Explanation of Above Diagram.

A B C D shows ground plan. A B 2 elevation of common rafter. 1 C to be the seat line of hip. Square from seat line C 1 out to D; space the curve 2 B into as many parts of parts, the more, the more accurate. Let fall from the numbers on the curved line perpendicular to the numbers on the seat line C 1. Square from the numbers on seat line 1 C commence and transfer from seat line 1 B in their respective places, to corresponding places on seat line of hip 1 C by those transfers. Points are found to trace curve theory. Cut and stand up as shown. Of all the cuts that are a source of annoyance to carpenters, the above is one that to many is most difficult of mastering.

The rule applies to the curved ribs of bay windows, also to roofs that curve both ways. Ribs for arbors also apply to roof of octagonal ground plans. M. J. MARION.

Science of Carpentry Made Easy.

A WORK that should be in the possession of every mechanic, as its pages are full of practical, instructive matter pertaining to carpentry, bridge building, etc. Price, $5.00.

How to Build, Furnish and Decorate.

SIX HUNDRED and fifty illustrations, consisting of plans for every kind of a building.

A PERFECTLY NEW WORK. PRICE, $10.00.

Indexed Atlas of the World.

BUT one copy left. Price, $30.00.

Stained Floors.

THE popularity of stained floors goes on increasing. Nowhere are they more appreciated than in sleeping-rooms, where sweetness and freshness are the main considerations. Just what is the best stain is a difficult question to decide. A writer in the London *Queen* is of opinion that permanganate of potash is the best. It is much used in the navy, and is very satisfactory in sitting-rooms and sleeping-rooms. As most people know, permanganate of potash not only stains, but purifies and disinfects the rooms which are stained. The mode of procedure is this; Procure a good quality of permanganate of potash; dissolve about an ounce and a half of the crystals in a gallon of boiling water—this will make quite a dark stain—use a stick to stir up the mixture; then with a painter's flat brush lay on the stain, working the way of the grain of the wood quickly and boldly. A small brush is useful for corners and crevices, and a pair of heavy gloves should be worn while at work, as the permanganate stains very considerably. Salts of lemon or the lemon juice will, however, quickly remove the stains from the hands. When dry the staining can be repeated if the color is not dark enough, and then when perfectly dry the floor should be rubbed dry with an old duster, and linseed oil should be rubbed on freely with a piece of flannel, always applying it with the grain of the wood. Two or three layers of the oil are an improvement, and firmly set the stain. The floor is then ready to be polished with beeswax and turpentine. To prepare this, spread or cut up the wax into small pieces; put it in a gallipot, and pour sufficient spirits of turpentine over it to just cover it; set the pot in the oven or on the stove until the wax is thoroughly melted, then set it aside to get cold, when it should be of the consistency of pomatum. Put on the wax—not too much of it—with a piece of flannel, and polish with a polishing brush or a big silk duster. This mode of treating floors is quite the best and most wholesome for bedrooms, which should be stained all over, under the beds and everywhere. They can be kept very clean and bright by a daily rubbing with the duster and a weekly application of beeswax and turpentine. Turpentine is cleansing, and floors so treated do not require the weekly scrubbing which is so objectionable in cold and wet weather. Some people object that these floors require so much labor; but after they are once well polished, the labor is not more than scrubbing floors and washing oilcloths, and they take away two-thirds of the terrors of house cleaning. Those who like the more common varnished floors should stain the floors as above, but instead of the linseed oil a coat of size should be laid on. This can be obtained at the paint shops, and should be dissolved in boiling water to the consistency of thin gum, and then laid on with the brush evenly and with the grain. When the size is perfectly dry and hard it can be varnished with one or two coats of copal or egg-shell flat varnish. These floors require to be dusted daily and to have a little linseed oil rubbed in occasionally. These require less care than a waxed floor, but when they get shabby they are not so easily renovated. A flannel bag in which the broom can be encased is the best floor duster and one most easily managed. - *Sel.*

The Manufacture of Glue.

GLUE is an inspissated jelly, made of the parings of hides and horns of any kind, the pelts obtained from furriers, the hoofs and ears of horses, oxen, calves, sheep, etc. These are first digested in lime water, to cleanse them from greace or dirt; they are then steeped in clean water with frequent stirring, afterwards laid in a heap and the water pressed out. They are then boiled in a large cauldron with clean water, skimming off the dirt as it rises, and further cleansed by putting in, after the whole is dissolved, a little melted alum or finely powdered lime. The skimming is continued for some time, after which the mass is strained through baskets, and suffered to settle, that the remaining impurities may subside. It is then poured into the kettle again, and further evaporated by boiling and skimming till it becomes of a clear darkish brown color. When it is thought to be strong enough, it is poured into frames or moulds about six feet long, one broad and two deep, where it gradually hardens as it cools, and is cut out when cold into square cakes. Each of these is placed in a wooden box opened in three divisions to the back: in this the glue, while yet soft, is cut into three slices by an instrument like a bow, with a brass wire for a string. The slices are then taken out into the open air and dried upon a kind of coarse network, fastened in movable sheds four feet square, which are placed in rows in the glue maker's field. When perfectly dry and hard it is fit for sale. That is thought the best glue which swells considerably without melting by three or four days' immersion in cold water, and recovers its former dimensions and properties by drying. Glue that has got frost or that looks thick and black, should be melted over again.

To know good from bad glue, the purchaser should hold it between his eye and the light, and if it appears of a strong, dark color, and free from cloudy or dark spots, the article is good.

To this account may be added some experiments on a glue made from the raspings and trimmings of ivory, the refuse pieces and shavings of the button mould makers, and other pieces of hard bone that cannot be turned to account in entire manufacture. Six pounds of button mould shavings were put into a copper boiler with twenty-four quarts of cold water, and first let soak for two hours. The fire was then kindled and the liquor slowly brought to boiling, and kept at this heat for nine hours. After standing a night, fourteen quarts of clear gelatinous liquor were drawn off by a syphon, and two quarts more were obtained by pressing the residue. This was duly evaporated without addition, and when of the proper consistence was allowed to subside for half an hour, when it became firm enough to cut into cakes, which being hung up for a fortnight in a barn, yielded fifteen ounces of solid glue, or rather less than a sixth of the weight of the bone shavings originally used. A similar experiment made with ivory turnings yielded nearly the same proportion of glue. The jelly from these clean white bones is at first very transparent, and with but little color, and when concentrated by evaporation it always deepens in color, but if well made still remains transparent. A piece of this glue put into cold water swelled, as happens with common good glue, and in twenty-four hours had absorbed fifteen times its weight of water, but without dissolving, and by again drying in the air it returned to its original bulk and weight. It appears that at Paris there are three sorts of glue commonly sold. The best is imported from England, and is of a deep red; the next in value is the Flemish, which is whitish and transparent, and the most ordinary glue of the country is black and opaque.

In using glue, the carpenters first break it and cover it with cold water, and let it stand for about twenty-four hours, by which, as already mentioned, it swells to many times its original bulk after which the soaked pieces are melted, without more water, over a slow fire and kept simmering for about a quarter of an hour, with frequent stirring, and are then cooled. It is now a firm jelly, of such a consistence as very readily to be cut by any instrument, but too stiff to be tremulous. When wanted to be used, it is merely warmed, which renders it sufficiently fluid to be spread over the surface of the wood with a brush Wood joined by glue requires from one to three days to be perfectly cemented, which is known by the hardness of the portion that remains on the outside of the joining; and the force of cohesion of the best glue is such that boards as thick as any commonly used in furniture carpentering will quite as readily give way to violence in any other part of the substance as at the joining. Glued boards will not set in a freezing temperature, the stiffening being owing to the evaporation of the superfluous water of the glue, which is prevented by great cold.

A variety of gelatinous cements of less firmness than common glue and known by the general term of *size*, are made for the use of paperhangers, gilders, bookbinders, house painters in distemper, and many other trades, by boiling down in water the clippings of parchment glove leather, fish skin, and many other kinds of skin and animal membrane. These are used either alone or mixed with vegetable tenacious substances, such as flour paste, gum arabic and tragacanth, and the like. The preparations of these jellies is very simple, the substance used (parchment shreds, for example) being merely dissolved in water by boiling, strained and evaporated to a due consistence. Eel skins and the skins of other fishes make a cement which is much valued for its transparency and tenacity.—*Furniture Gazette.*

MASONS' and BUILDERS' EXCHANGE
OF SAN FRANCISCO,
Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

"Ancient Lead Work," American Architect and Building News, Boston.
"Healthy Foundations," Sanitary Engineer, New York.

METROPOLITAN FOUNDRY,
228, 230 and 234 Fremont St., San Francisco,

Manufactures all kinds of

BUILDING CASTINGS.

Estimates furnished on

ALL KINDS OF CAST IRON WORK.

A full assortment of

SASH WEIGHTS

Constantly on hand and made to order in any shape or style; also weights for Dumb Waiters, Elevators, &c., &c.

ALL KINDS OF VENTILTORS

In Stock and Made to Order

Carpenters & Builders

SHOULD send for the best **COMBINATION TOOLS** for Clapboarding. Take the place of all the old tools except the saw and hammer. They are made of the best malleable iron, nicely japanned and nickel-plated, neatly packed in a box with full directions for using. If your hardware dealer does not keep them we will send them to you on receipt of $3.50. Parties ordering together will save on express charges. Can be sent by mail for additional 60 cents. Address BASSETT & WASHBURN, Plainville, Connecticut.

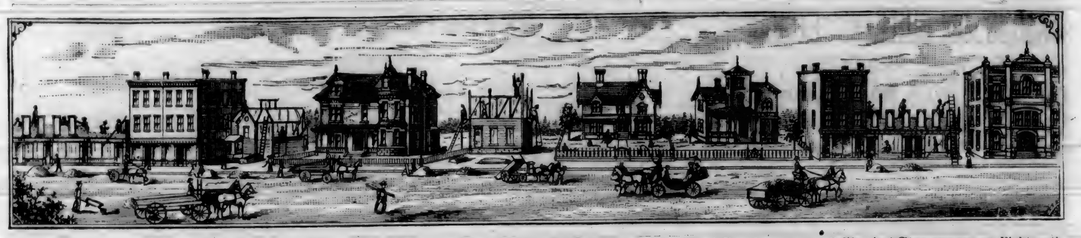
S. F. Architectural Publishing Co., Sole Agents for Pacific Coast, 240 MONTGOMERY STREET, SAN FRANCISCO.

ALL THOSE ORDERING BOOKS TO THE AMOUNT OF $11.00 WILL RECEIVE—FREE—ONE YEAR'S SUBSCRIPTION TO THE CALIFORNIA ARCHITECT AND BUILDING NEWS.

Promptly forward your subscription for 1884.



We do not answer ANONYMOUS communications.
Contractors are not regarded as architects, simply because they do, at times, make plans for buildings.
Friend, Architector, Constant Reader, old subscriber and others, by sending us their proper names, will receive letters in answer to their questions

Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

Semi-Annual Review of Building Operations in San Francisco.

A MORE THAN FAVORABLE SHOWING.

DURING the first six months of 1884 up to the 10th of the present month, more buildings and of greater value have been erected than for any similar period since records of the same have been kept. The showing given is the more remarkable from the fact that many of our real estate agents considered the large number of flats which were erected last year would be ample to meet the demand for a while, and that only occasionally similar structures would be erected during, at least, the first six months of the present year.

In a labored article in the *Chronicle* on building operations, we find that "it is now thought the number of new buildings to go up this season will hardly equal that of 1883." The writer evidently did not know the true state of facts. We have reported each month the number of contracts actually signed, and even a casual observer could not help but notice that the number of buildings was considerably larger than that of last year. The true value of such a statement is best shown by the following résumé:—

In the first six months of 1882, there were reported in this Journal, of building improvements—brick, frame, and alterations—

281 Buildings of the value of $1,238,910;

Same time in 1883,
424 Buildings of the value of $2,464,898;

For the first six months of 1884,
521 Buildings of the value of $3,188,670.

IT WILL THUS BE SEEN THAT NEARLY 100 MORE BUILDINGS HAVE BEEN ERECTED, OR ARE IN PROCESS OF ERECTION, MORE THAN FOR ANY SIMILAR PERIOD OF WHICH WE HAVE ANY RECORD; BEING A COMPLETE REFUTATION OF THE "CHRONICLE'S" STATEMENT.

There are several improvements under way not counted in the above estimate. It is our rule not to give building items until the contracts are signed, and for this reason we do not include the Murphy building, corner Jones and Market; grading has been commenced and estimates are now being received. Probably nearly half a million will be spent on this property.

Work has also been in progress for some time on the "Fair" property on Nob Hill, but we have as yet made no allowance for same in our estimate. The old Metropolitan Market Building is now being torn down to make room for a fine brick structure; as the contract is not yet signed, we do not report the same. Many others might be quoted to prove that the building boom is much greater than our figures show, but we do not anticipate events in order to swell the record. We have given, each month, a faithful record of the number of buildings actually in process of erection, and one that can be relied upon as substantially correct

We can see no good reason to apprehend a falling off in the number of new buildings to be erected in the remaining months of the year. The indications at present are, that they will exceed in number and value those of the same period in 1883.

Every kind of labor can, at present, secure remunerative employment. First-class carpenters are scarce. Masons are in good demand, a thorough mechanic being but seldom out of employment. When carpenters are busy, lathers, plasterers, plumbers, painters, etc., must necessarily, have plenty of work.

Our article in last issue on "High Price of Brick," attracted much attention, and we received a gentle chiding (?) from some of the prominent manufacturers in regard to the same. We do not think brick will be held at so stiff figures after the middle of July.

The inclination among the Lumber Manufacturers is to shade off on the prices in schedule. In fact, some of the shades are quite heavy. Prices favor the buyers, especially when large quantities are furnished. We are pleased to see this good work commenced. Twenty dollars per thousand is the most that rough lumber ought to command in this city.

From the number and character of buildings now in course of erection, one can readily form a true idea of the prosperity and growth of our city. More than anything else that has contributed to this result, is the steady decrease of the mining excitement, and the sooner the "Big Board" is dissolved, the better it will be for our real estate and building interests.

San Francisco Chapter, American Institute of Architects.

THE regular monthly meeting of the Chapter was held on June 6th, H. C. Macy presided. It being the desire of the members present to attend the meeting in honor of the Presidential nominees, the routine business was dispensed with. Several communications were laid over until next meeting. J. J. Clark as Fellow, and L. M. Turton as Student, were elected members of the Chapter. Proposi-

tions for membership were received from A. A. Bennett and Emil John.

A long and earnest discussion then ensued upon the advisability of allowing one member of an architectural firm to belong to the Chapter when the other member or members do not desire to join. No definite conclusion was reached.

Committee on Indentures presented a report which was laid over till next meeting. The secretary was authorized to have printed a number of copies of the by-laws, immediately upon receiving the articles of Incorporation of the Chapter, and to combine the latter with the by-laws.

The meeting adjourned to Friday evening July 11th, as the regular night comes on the 4th, said day being a national holiday.

Division Fences.—The "Call" in Error.

A CORRESPONDENT asks, through the question column of the *Morning Call*, whether the respective owners of lots are obligated to bear equal proportions of cost of fences built upon the division line.

The *Call*, which in matters with which it is familiar generally returns correct answers to its querists, is correct in saying, "If two persons own adjoining lots, and one wishes to fence around his lot, he cannot compel the other to share the expense of the division fence between the two lots," but it is greatly in error in stating, "But afterward, if the owner of the second lot desires to fence in his property, he *must* pay half cost of the division fence if it is used as the only fence between the two lots." There is no legal rule or law justifying the use of the word "MUST pay." Morally, it would be only fair and just for the second owner to pay half cost of the division fence, but if he does not see fit to do so, the one who built the fence can have no financial redress in the cost thereof. He may by law prevent the second party from using such fence for the purpose of attaching clothes lines, sheds, or other constructions, or in any manner making use thereof, by nailing or securing to it. But the second man may enjoy the use of such fence for all the purposes of inclosure simply, without paying a farthing toward the cost of erection.

The Ordinances Regulating the Construction of Buildings in San Francisco.

THE "orders" defining the Fire Limits and regulating the construction of both brick and frame buildings in San Francisco, has been printed and bound in convenient form, containing 114 pages. The copy before us is the latest upon the subject matter regulated, having been passed by a vote of eleven to one in the board of supervisors, February 27, and approved by his honor, Mayor Bartlett, March 3, 1884.

The objects in view with those originating the various orders as passed, were evidently to define and enforce the practice of safe and secure methods of construction, with fire risks and dangers as the basis of judgment, and the conclusions reached. The necessity for a perfect and equitable code of ordinances to regulate and prevent the many abuses that have been so commonly and generally practiced in San Francisco, is admitted by all intelligent architects and builders; for the violations and disregard of the correct science of construction and mechanical principles in the erection of buildings in California, are very numerous; and it is not a matter of surprise that those to whose special care the fire interests of the city are confided, should be alive to the importance and necessity of buildings being so constructed as to insure, first, the greater security against the occurrence of fire, and the best means and facilities in controlling conflagrations when they do occur; secondly, to diminish the risks and dangers always more or less possible to firemen during active service, and thirdly, the most practical and safest means of escape to occupants of burning buildings; all of which is proper and wise, where *common rights and privileges* are not unnecessarily proscribed and restrained. But it is possible, and a thing that has often been done by law-making powers, to go beyond limits at which they should stop; for there is the possibility in law and ordinance making, as in all the other affairs of life, of attempting, comprehending, and seeking to cover and do too much, thereby making legal enactments, passed presumably for the protection and bettering of matters and interests legislated upon, onerous and oppressive, and therefore unjust.

How nearly the exactly right and fair has been reached in the passage of the "fire limit orders," or how handsomely the overstepping of legitimate and proper bounds has been avoided, is a question undoubtedly affirmed and claimed by the framers of the "orders," while architects, contractors and owners very generally disapprove and oppose many of the provisions and regulations of the book of orders and submit thereto with no special manifestation of good grace.

The dissatisfaction that exists arises largely from the fact that there are many really competent architects and builders in San Francisco, who claim to, and do understand and know as perfectly, exactly and comprehensively the numerous requirements involved in building constructions, as do the law-making powers, whose knowledge of building matters and principles is almost exclusively second-handed, and devoid of any more than incidental personal experiences as to architectural or building sciences. And when such men are confronted in the exercise of their professional and mechanical practices, by legal orders and ordinances which in many of their details are considered as unnecessarily restrictive, faulty, and not of recognized consistency and practical utility, it is the most natural thing imaginable that a rebellious feeling should exist.

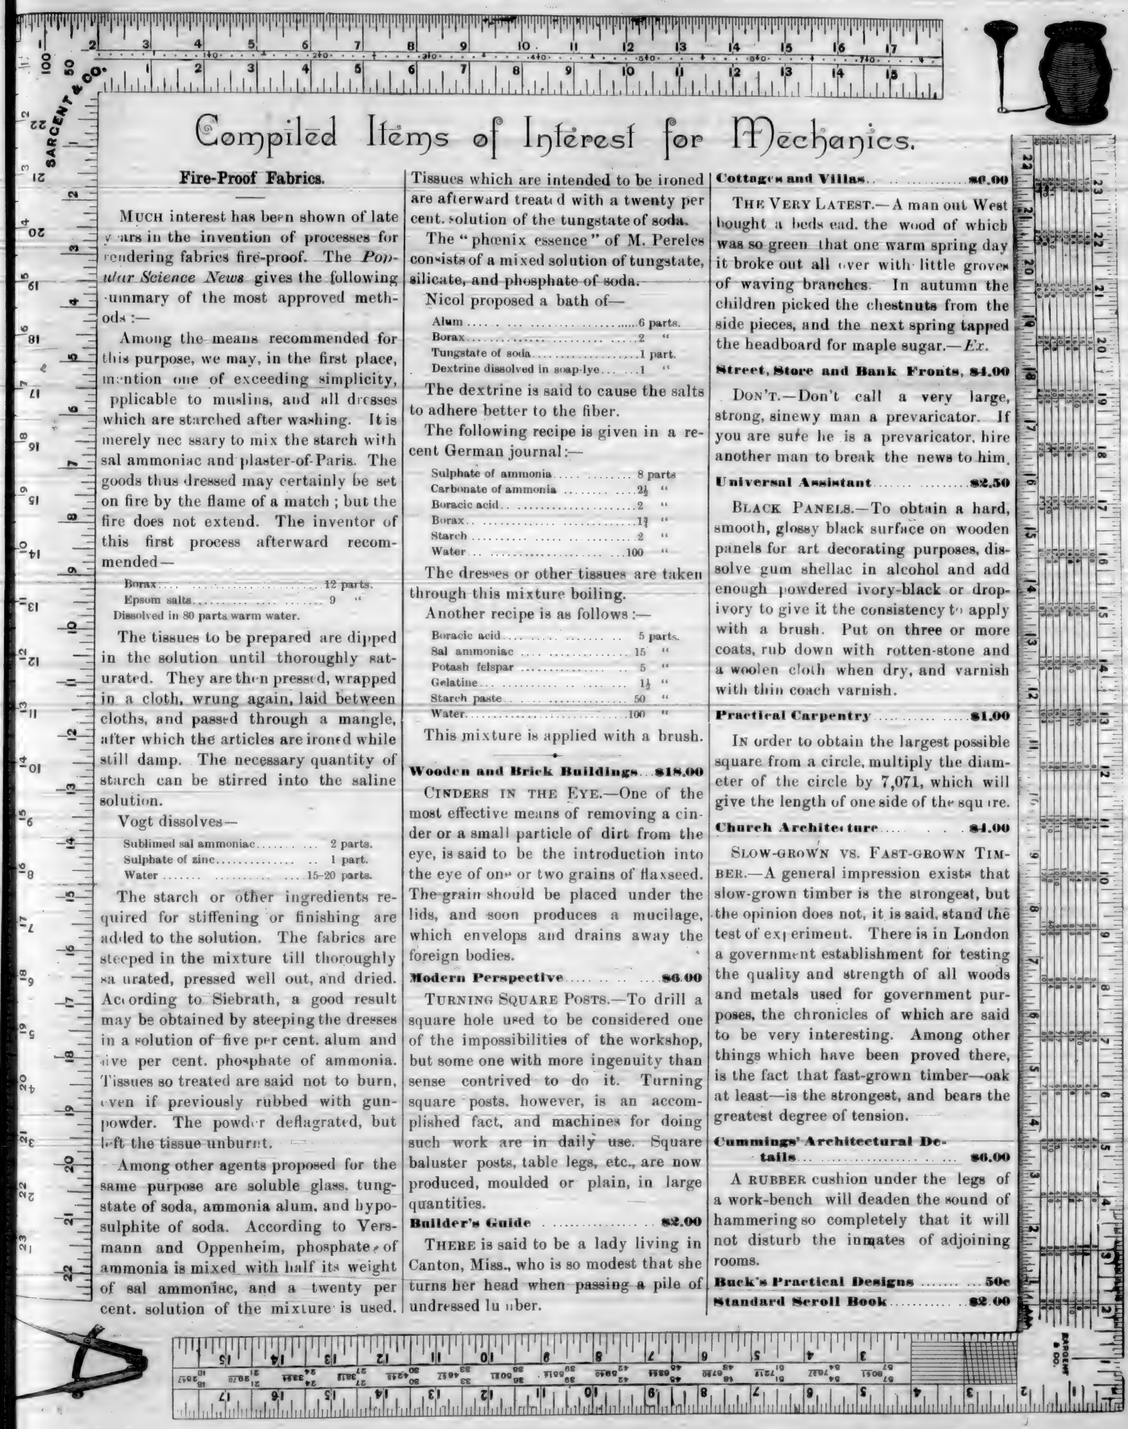
Reference is made to the subject under notice, simply because the feeling is so general, and so freely expressed by architects and others, in reference to many of the provisions of the "orders," which, in the main, are good, sound and proper; and if purged of the objectionable features, would meet the hearty approval of all competent and worthy architects and builders, as both the professional and mechanical departments of building science are infested with men whose attempts at designing and construction require laws and orders to force them to even half consistent practices, and who would be much nearer their proper spheres of operation with the reins of a mule team or a pick and shovel in hand.

Buildings.

SECTION 48 of the "Fire Limit Order," as passed by the Board of Supervisors, provides that all doors of ingress and egress, to and from halls and buildings used for public assemblages, *shall open both ways—inwardly and outwardly—and in no case inwardly only.*

The section not defining explicitly the class of buildings contemplated, and included in and by the intent and meaning of the order, beyond the general expression, "*all buildings . . . used for public assemblages,*" the fraternal organizations people claimed that the order was not intended to reach and include halls and buildings devoted to secret society purposes, and the late decision of Judge Ferral in the appeal case of District Engineer Kennard vs. John Goldman—the defendant having been arrested for misdemeanor, and tried in the Police Court for non-compliance with the order requiring entrance doors to halls to open outward—sustains the theory that lodge room buildings are not public halls, and therefore not subject to the provisions of the "Fire Limit Order!"

A QUESTION is raised by *La Semaine des Constructeurs* which is of some importance in this country as well as in Europe. One of its correspondents in speaking of the items which should be included in the cost of a party-wall, for the purpose of determining the amount that should be paid by a person wishing to use it to support an adjoining building, remarks that, according to the decision of the courts, the owner of the wall is not entitled to include the architect's commission of five per cent. as a part of the cost of the wall, half of which the adjoining owner is bound to pay in return for the privilege of using it. This seems to the correspondent, as well as to the editor of *La Semaine*, rather unreasonable, and the latter even goes so far as to say that where the party-walls had been constructed without the intervention of an architect, the owner should still be entitled to add the usual architect's commission, as compensation for the trouble which he had been at in making contracts and supervising the work. As five per cent. on the value of half an ordinary city party-wall would be from fifty to a hundred dollars, or even more, it ought to be worth some one's while to settle the question definitely. Although we have heard the point discussed here, we have never seen the architects percentage specified as an item in the account of the cost of a party-wall. If any one of our readers knows of local customs or precedents favoring a different practice, we should be very glad to be informed of them.—*American Architect and Building News.*



Compiled Items of Interest for Mechanics.

Fire-Proof Fabrics.

MUCH interest has been shown of late years in the invention of processes for rendering fabrics fire-proof. The *Popular Science News* gives the following summary of the most approved methods:—

Among the means recommended for this purpose, we may, in the first place, mention one of exceeding simplicity, applicable to muslins, and all dresses which are starched after washing. It is merely necessary to mix the starch with sal ammoniac and plaster-of-Paris. The goods thus dressed may certainly be set on fire by the flame of a match; but the fire does not extend. The inventor of this first process afterward recommended—

Borax	12 parts.
Epsom salts	9 "

Dissolved in 80 parts warm water.

The tissues to be prepared are dipped in the solution until thoroughly saturated. They are then pressed, wrapped in a cloth, wrung again, laid between cloths, and passed through a mangle, after which the articles are ironed while still damp. The necessary quantity of starch can be stirred into the saline solution.

Vogt dissolves—

Sublimed sal ammoniac	2 parts.
Sulphate of zinc	1 part.
Water	15–20 parts.

The starch or other ingredients required for stiffening or finishing are added to the solution. The fabrics are steeped in the mixture till thoroughly saturated, pressed well out, and dried. According to Siebrath, a good result may be obtained by steeping the dresses in a solution of five per cent. alum and five per cent. phosphate of ammonia. Tissues so treated are said not to burn, even if previously rubbed with gunpowder. The powder deflagrated, but left the tissue unburnt.

Among other agents proposed for the same purpose are soluble glass, tungstate of soda, ammonia alum, and hyposulphite of soda. According to Versmann and Oppenheim, phosphate of ammonia is mixed with half its weight of sal ammoniac, and a twenty per cent. solution of the mixture is used. Tissues which are intended to be ironed are afterward treated with a twenty per cent. solution of the tungstate of soda.

The "phœnix essence" of M. Pereles consists of a mixed solution of tungstate, silicate, and phosphate of soda.

Nicol proposed a bath of—

Alum	6 parts.
Borax	2 "
Tungstate of soda	1 part.
Dextrine dissolved in soap-lye	1 "

The dextrine is said to cause the salts to adhere better to the fiber.

The following recipe is given in a recent German journal:—

Sulphate of ammonia	8 parts
Carbonate of ammonia	2½ "
Boracic acid	2 "
Borax	1¼ "
Starch	2 "
Water	100 "

The dresses or other tissues are taken through this mixture boiling.

Another recipe is as follows:—

Boracic acid	5 parts.
Sal ammoniac	15 "
Potash felspar	5 "
Gelatine	1½ "
Starch paste	50 "
Water	100 "

This mixture is applied with a brush.

Wooden and Brick Buildings.....$18.00

CINDERS IN THE EYE.—One of the most effective means of removing a cinder or a small particle of dirt from the eye, is said to be the introduction into the eye of one or two grains of flaxseed. The grain should be placed under the lids, and soon produces a mucilage, which envelops and drains away the foreign bodies.

Modern Perspective.....$6.00

TURNING SQUARE POSTS.—To drill a square hole used to be considered one of the impossibilities of the workshop, but some one with more ingenuity than sense contrived to do it. Turning square posts, however, is an accomplished fact, and machines for doing such work are in daily use. Square baluster posts, table legs, etc., are now produced, moulded or plain, in large quantities.

DON'T.—Don't call a very large, strong, sinewy man a prevaricator. If you are sure he is a prevaricator, hire another man to break the news to him.

Universal Assistant.....$2.50

BLACK PANELS.—To obtain a hard, smooth, glossy black surface on wooden panels for art decorating purposes, dissolve gum shellac in alcohol and add enough powdered ivory-black or drop-ivory to give it the consistency to apply with a brush. Put on three or more coats, rub down with rotten-stone and a woolen cloth when dry, and varnish with thin coach varnish.

Practical Carpentry.....$1.00

IN order to obtain the largest possible square from a circle, multiply the diameter of the circle by 7,071, which will give the length of one side of the square.

Church Architecture.....$4.00

SLOW-GROWN VS. FAST-GROWN TIMBER.—A general impression exists that slow-grown timber is the strongest, but the opinion does not, it is said, stand the test of experiment. There is in London a government establishment for testing the quality and strength of all woods and metals used for government purposes, the chronicles of which are said to be very interesting. Among other things which have been proved there, is the fact that fast-grown timber—oak at least—is the strongest, and bears the greatest degree of tension.

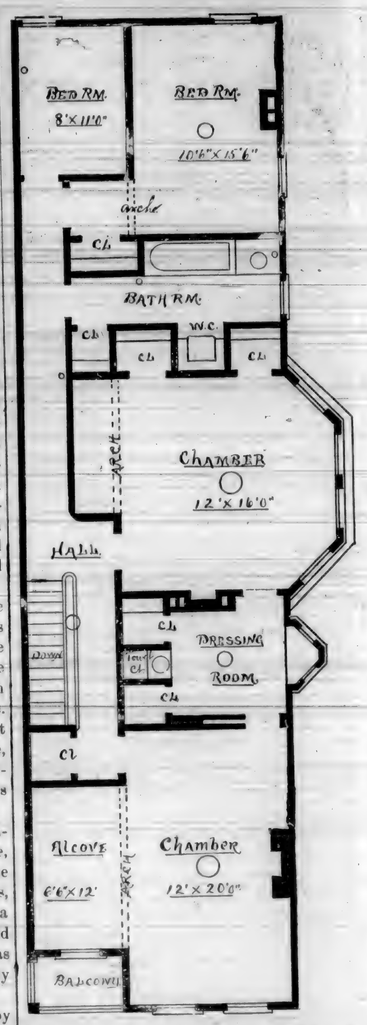
FIRST FLOOR PLAN OF $5,500 DWELLING.



SECOND FLOOR PLAN OF $5,500 DWELLING.

Our First Competition—Result.

AFTER a thorough and impartial investigation of the numerous plans presented by applicants, for the various awards offered by the proprietors of this Journal, the Committee have awarded the Premiums as follows:—

FIRST PRIZE; "AS YOU LIKE IT."—Author, Junius H. Morse, 10 Pemberton Square, Boston, Mass.

SECOND PRIZE; "GARRICK."—Author, John C. Wolf, 57 Broadway, New York.

THIRD PRIZE; "ORIOLE."—Author, W. Claude Frederick, 65 West Fayette St., Baltimore, Md.

FOURTH PRIZE; "Hoosier."—Author, J. W. Hammond, Frankfort, Ind.

HONORABLE MENTION; "TEASE QUARE."—Author, Oliver C. Smith, S W. cor. 6th and Vine Sts., Cincinnati, Ohio.

We publicly extend our thanks to the Committee, Messrs. Sanders, Pissis, and Mitchell, for their earnest efforts in arriving at the result. It was a task of more than unusual difficulty to decide upon the merits of the various plans. That their decision was just is evinced by the fact that not a single premium was awarded to competitors on this coast. Hence, no partiality was shown in making the awards.

After receiving the plans from the Committee, we carefully studied the various designs, and are satisfied that good judgment was exercised in declaring the result, as stated. We could not help but notice a general fault with all the designs. There is not a single one that can be built for anything like $5,000 in this city, and, strange to say, the plans presented by competitors residing in California, were as far out of the way in this regard as those from the East. We also noticed carefully the estimates, and found that, although they were all near the required amount, still there were many items much too low, and many omitted altogether.

In one estimate the price of brick laid in the wall was given at $12.50 per thousand. This figure is so much at variance with the price in this city, viz. $20.00, per thousand, that we are at a loss to conceive the conditions which would naturally give rise to such a difference.

In another case, the labor was placed at $1,350. This seems incredible in a $5,000 house, but not hardly more so than is given in another estimate for work where the same is placed at $430.

We very much regret that one of the contestants should have gone to the Committee, and, without the advice or sanction of the Editors of this Journal, withdrawn his plans, simply b cause he thought he could not get a premium, and therefore concluded he would withdraw the same before the result was announced. Being a new-comer, we generously overlook the affair.

We sincerely regret the apathy shown by architects and draughtsmen residing on the Pacific Coast, in regard to presenting plans for this competition. The premiums—$60, $50, and $40—for the first three prizes were certainly worth striving for, and when, in addition to the money, the publicity given to the successful authors of the various designs is taken into consideration, we are surprised that more energy was not exercised by our California brethren in striving to secure at least *one* of the prizes.

As a whole we are well pleased with the result. There were more plans received than we had hoped for when our offer was made. Those receiving premiums, and those of whom honorable mention is made will appear in successive numbers of this Journal, the first of which will be in our July issue.

It is our intention to shortly issue a prospectus for our SECOND competition. This will be for a country dwelling to cost not over $3,500. To avoid such discrepancies in estimates as were contained in the *first*, we will specify distinctly the prices to be used for lumber, brick, etc. Parties desiring to compete will please send us their address as soon as convenient. This second competition is OPEN TO ALL.

All our competitions will be under the control of a committee appointed by the S. F. Chapter A. I. A., thus ensuring absolute fairness in the awarding of premiums.

CITY OR SUBURBAN DWELLING, COSTING ABOUT $5,500.

The Journeymen Painters' Movement.

At the time of going to press with the April number of this Journal, the issue between the master and journeymen painters remained unadjusted, with the indications strongly in favor of the workmen. Since then the anticipated concession has been made by the masters, and the journeymen are joyous over their success in securing the advance in wages demanded.

As was stated in a former issue, the resistance on the part of employers was influenced by a virtually *criminal* wrong existing with so many of those who assume the position of masters, whose regular business practice has been, and is, to swindle and rob owners through contract engagements, and honest bosses by the use of all manner of stuff manipulated into a solution made to resemble, to the unpracticed eye and credulous owners, the appearance of paint. And in *fact* a paint—for the term paint is defined by Webster's unabridged as, "*To cover or smear over with coloring matter.*" Consequently any mixture that can be applied with a brush, and which gives color, comes under the name of paint, the ingredients used not being defined or expressed by the term. But when the painting of a building is let, either upon the basis of a specification or upon a verbal understanding, the universal presumption is that white lead and pure linseed oil shall constitute the pigments of the color used, and honest painters so understand the matter and govern themselves accordingly in fixing a value for the work to be done; while the "professors" of the adulteration art, destitute of all mechanical pride and principles, resort to the use of base mixtures, fifty to ninety per cent of which cannot be found nor purchased of any reputable house manufacturing or dealing in white lead, pure oils and genuine paint stock.

Consequently the honest men who do use the proper materials, and are faithful to their employers, stand no equal chance when the "professors" are allowed to compete. It is not reasonable to suppose that those who use genuine paint stock, costing, say ten cents per pound more or less, have any comparative standing with those who use slush, costing three to five cents per pound. And it is this unequal grievance that seemed to compel the master painters to resist an advance, while the "professors," knowing their advantages, could, with financial safety, acceed to the demand for increased wages on the part of journeymen.

The terms *"swindle and rob"* have been used in this article; are they warranted? Emphatically, yes. Robberies and swindles are of unlimited kind and varying degrees, and those who, through contract opportunities, obtain money from owners in payment for material used and work performed, differing from, inferior to, and of far less value than that covenanted and agreed to be used, are nothing less than a special class of swindlers and cheats. Yet the class of owners who let their work to such men, simply upon the ground that the parties offer to do the work at a very low price, without any regard to the standing or reputation of the persons engaged, merit all the bad usage received; while that fact does not lessen nor justify the rascalities of those who abuse and degrade a mechanical pursuit, about and around which clusters so many grand and sublime facts in history, in the arts and sciences, and in the grandeurs of the universe, with its mountains, fields and valleys made beautiful by the Artist of eternity, in the millions of tints, hues and colors spread out over all of earth's surface, each shade being in and of itself pure and unadulterated, proclaiming to the world their origin through the perfect and pure laws of natural growth, as established by Him who organized the perfect system of truth and love, brought forth by each return of seasons, and who added to the sun's golden rays, the soft moonbeams of night, and completed the beauties of the firmament by changing clouds of unspeakable grandeur and the colors and tints of arching rainbows.

But we leave the subject in hand for the present, to be further considered and treated when we shall have gathered and added to our practical knowledge of the matter other information in detail, sustaining and confirming all that has been outlined in this article.

To this end we ask the assistance of all reliable users of pure paint material, whether masters or journeymen, assuring them that authenticated facts alone, without the use of name, will be used in this connection.

The Strength of Wood.—It may seem strange, says the *Midland Industrial Gazette*, that a board one inch in thickness, of any solid wood, requires less force to tear asunder than one of the same thickness composed of a number of layers of wood, the resistance being augmented by crossing the grain. For instance, five samples of lumber, as represented in the following, were carefully adjusted and subjected to tension with these results:—

Walnut, solid	87.4	pounds	to tear	asunder.
Gum, "	98.7	"	"	"
Poplar, "	71.13	"	"	"
Cherry, "	84.07	"	"	"
Ash, "	69.91	"	"	"

One-fifth of an inch of each sample was now placed together, grain all running in one direction, when, after being glued and thoroughly dried, it required a strain of a trifle over 100 pounds to tear apart, and the strangest feature of all was it separated with the wood that showed the greatest resistance when tested solid, hence though the resistance is increased in all, the weaker woods show the greater. Again, the grain was crossed with each layer alternately when the resistance was still further increased 28.5 pounds, and when crossed diagonally we found a better result still, it being about 80 pounds greater than required to split or tear asunder the original wood.

Practical Perspective, $6.00.

Practical Carpentry, $1.00.

Nails.

A large dealer in builder's hardware said recently that the demand for clinch or clout nails and for chisel pointed wire nails had largely increased within a year, as compared with that for the ordinary cut nails, and that flooring nails with the wedged-shaped heads were also used in place of the nails with the flat upset heads. His reasons were that better work resulted from the better nails, and there was far less waste. For the coarsest purposes the less first cost of the ordinary cut nails with the flat head induced builders to continue their use; but he believed the improved form and better material of the tough wire and clinch nails would, in time, drive out the inferior material and defective form. The principal advantage of the wedge-shaped head, as in floor nails, is that the head never breaks off in driving, as it is only a gradual enlargement of the body of the nail, instead of an upset across the nail. But the chisel point of the wire nail is its especial merit, as it cuts a clean passage through the fibers of the wood for the following of the body of the nail, instead of "stunting" and mutilating the fibers, as the blunt-pointed nails do.

The common cut nails will not usually clinch, even when the clinch is turned in the direction of the grain of the wood; but they may be considerably toughened by heating to a red, and gradual cooling. A hardware establishment was burned a few years ago, and among the stores were nearly a hundred kegs of cut nails of various sizes. The remains from the fire were sold to another dealer, and as soon as the value of the burned nails became known he could sell no others until they were gone.

The Little Shop.

It is time that notice should be taken of the work done, as well as of the place taken, by our small shops. The "big concerns" do not monopolize all the skill and mechanical capability in the country. They may profess to do the best work and produce the best results, because they are furnished with the best tools, but they do not monopolize all the mechanical skill, nor collect all the best workmen Many of the best manipulators, and a very large proportion of the most exact mechanics, are in the little shops, content, may be, to be the foremen, when in a big shop they would be only first-class workmen. The small shop men are valuable in any shop where mechanics, rather than operatives, are required, because they are generally "men at a pinch," "expediency men," and generally excellent workmen.

The proprietor of a large manufacturing establishment, building fine tools of a particular character, claims that his best men come from small shops, where make-shifts and contrivances are the rule. "Such men," he says, "can make the shop hum" by their methods.

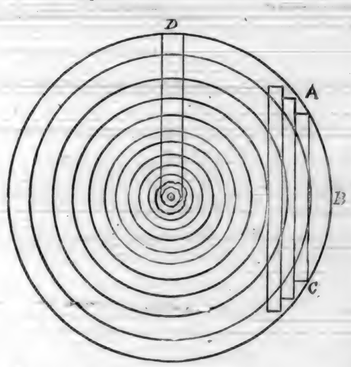
It is very convenient to have a shop full of adapted tools, but it is also convenient to have in the shop graduates from "the little shop," who can contrive, as well as tend, a machine. —*Scientific American.*

A Few General Designs for Country Dwellings.

Strength of Wood.

It is a fact well known to builders that the same varieties of wood will bear different weights, when placed in different positions as regards the running of the grain. Again, it has been repeatedly demonstrated that, at certain angles, timber will sustain greater weight than at others. There are certain well defined laws governing this that will be explained further on. To introduce properly a subject of this kind, it is expedient that we define more clearly the changes which wood undergoes from the time the tree is felled until the wood rots. All lumbermen have noticed that wood contracts less in diameter than in circumference. This disposition of inequality will explain why whole timber generally contracts in drying. In consequence of this irregular contraction, a board may be cut from a tree that, by any means known, cannot be made to retain its original shape, especially if subjected to alternate dryness and moisture constantly, as with exposed lumber in this climate.

If we take a log of any timber when cut clean, it will show up something like the following, though the rings will not of necessity present the regularity as represented in Fig. 1, still this plan will illustrate our meaning.



If we cut a couple of boards in different directions relative to their transverse septa, so that the septa crosses the middle of one board at right angles, while on the other they lie nearly parallel, then place these in a warm room under similar circumstances, we will find the board which has been formed by cutting across the transverse septa, as at *a*, Fig. 1, soon changes its form very perceptibly, the one side becoming concave and the other convex, and in seasoning it will contract nearly 14 per cent. in width. The board taken out at *d*, where the septa is nearly parallel with the surface of the board, will retain, with slight variations, the form it assumed on leaving the saw, and will not contract to exceed one-fifth as much as the other in width, but nearly equal the contraction in thickness.

In the softer, gummy and resinous woods, the difference is still greater than in the hard woods. It follows, then, from these experiments, that there is great advantage to be derived by a proper attention in cutting out boards for panels, etc. It will be found that panels cut in such a manner that the septa are nearly parallel to their faces, will appear of a finer and more even grain, requiring less labor to dress, make smooth, and give a good finish if not painted, or to take less oil if painted and grained. To be sure, this making all the boards with the septa in this relative position as regards the surface, is impracticable, inasmuch as the heart of the tree would have to be discarded. To overcome this seeming obstacle is not difficult by any means. When a board seasons, it always becomes concave on the surface nearer the outside of the tree, and *vice versa;* or, in other words, to use a common phrase, the concentric rings seem to be straightening out, hence the board will be hollow where the ring would indicate, simply because the rings of the wood, when cut across, are relieved from tension, and in their endeavor to expand themselves, cause the hollow on the outside and the ridge on the opposite side. So, if the board be ripped down the center and the stuff turned inside out, the wood is reversed, and one contraction counterbalances the other, and the board seasons even, and in this way the most perfect glue joints can be made; and for the manufacture of fine goods, such as furniture and the like, more especially in oil finishes, the effect of this change is indeed beautiful.

There is another kind of contraction in wood while being dried, of great inconvenience and trouble to builders. This is a tendency of some woods to curve in the direction of length. Often this disposition manifests itself after the timbers are framed and in position, causing a repetition of labor, or leaving a crooked job as an enduring monument of poor or slighted work. We often find walls and ceilings out of true, and blame the architect or builder, when the real fault, if such it may be called, is with the elements and physical forces over which man has little or no control. In the long style of framing, for instance, it has often been observed how difficult it is to prevent the stile of a door, hung with centers, from curving, so as to rub against the jamb. To overcome this is not difficult, if we will stop and consider that the interior layers of wood, being older, are more solid and compact than the exterior layers of the same tree; consequently in drying, the latter contract more in length than the former. This unevenness or irregularity of contraction, causes the wood to curve in the direction of the length, and may be avoided by cutting the parts of each piece so that they shall be as nearly the same age as possible. But inasmuch as this would necessitate considerable waste of lumber, it can be overcome by taking pains to always turn the stuff so that the heart of the wood will be outward. Then in framing a door the heart of the wood should always go against the jamb, the sap against the panels.

Architects' Companion, $2.50.
History of Architecture, $15.00.

Growing Black Walnut Trees.

Black walnut can be grown from the nut, producing a butt fourteen inches in diameter in as many years from the seed, as far north as Massachusetts. No tree valuable for its timber in cabinet uses, unless the black birch be so considered, can attain to that useful growth in that period of time in our northern climate. Maples require twenty years before they become good timber trees; beeches and birches, fifteen years to attain to a diameter large enough to yield nine-inch boards; hickory should have a growth of thirty years, and cherry at least as much.

The cultivation of the black walnut might be made a source of profit, if only as an auxiliary to the ordinary farm products. It requires no particular care, makes as elegant tree, even in its youth, and later offers an agreeable shade.

One hundred acres of land, seeded to walnut trees, if they even reach maturity in fifteen years, would be more remunerative than many of the crops produced by fifteen of incessant toil. Besides, these trees might be planted and would thrive on spots which are really valueless for agricultural purposes, and while in the course of growth would serve as valuable aids to agriculture as wind-breaks, and in other respects.

A Watch Made to Be Pounded.

When a visitor to the office of the American Bank Note Company sat down to talk to Mr. Lee, that gentleman put a piece of white paper under a stamp, pounded on it, and laid the paper aside. When the visitor rose to go away, Mr. Lee put the paper under the stamp again and pounded it once more. "You talked eight minutes," said he; "that wasn't bad." He showed the paper to the caller, who saw upon it two printed clock dials. One showed the hands at four minutes to 4 o'clock, the other showed them at four minutes past 4 o'clock. "We keep that stamp," he said, "so that you sha'n't go away and say you came here at 11 o'clock in the morning, or that you had to wait an hour and a half, or make any other misstatements which can be guarded against."

"No," he added, a moment later; "that stamp is the latest wrinkle in office furniture. It is an ordinary stamp with a clock attachment. The hour hand is simply a raised point upon a movable circle. The minute hand is an arrow on another revolving circle. The usual inked tape passes over these indicators and the outer circle of hour figures. Beside the clock face is a cylinder with several faces, each bearing a word—one is 'approved,' another is 'wired,' another is 'answered,' others are 'delivered,' 'Lee,' 'received.' Thus a business man is able, whenever he sends away a letter, telegram, or package, receives an order, or transacts any business whatever, to record the precise moment at which the thing was done. It costs $20.00. I did not invent it. I bought it."—*N. Y. Sun.*

A. A. Bennett.

Mr. A. A. Bennett, to whom this brief biographical sketch refers, was among the earlier arrivals to our golden shores, and a description of his coming will be found full of interest. He, together with thirteen other pioneer spirits from Alabama, banded together and styled themselves "The Montgomery Company," consisting of Mr. Bennett, Dr. A. Gindrott, J. H. Paul, J. H. Skates, J. Yarbrough, S. Cole, P. Bibb, H. Smith, J. B. Davison, E. Lynn, Col. D. M. Boyd, George Albright, Mr. Klock, and Mr. Lindsey, a Baptist clergyman from Mobile, sailed from New Orleans in the steamer *Galveston*, early in 1849, and when in the Carribean Sea, on Washington's birthday, February 22d, she broke her piston-rod and was obliged to rely solely on the limited quantity of canvas she spread to carry her into port, so the Captain made for British Honduras, arriving there safely. Here, part of the passengers, Mr. Bennett among them, chartered the British brig *Thetus*, which conveyed them to Chagres, the steamer being afterwards towed to New York. The company went up the Chagres River in small boats to Gorgonia, and from there Mr. Bennett tramped to Panama in one day, carrying his rifle on his back and hiring natives to carry his baggage. On their arrival at Panama, they found the people panic-stricken from dread of cholera, which was then epidemic there. After remaining there two months the company embarked, with 365 passengers, on the old ship *Alexander Von Humboldt;* were 102 days reaching the Golden Gate, stopping a short time, for supplies, at Acapulco. At last the old ship, after being tossed by wind and wave, landed her human cargo at San Francisco, the landing taking place on the 30th of August, 1849, the boats touching ground where the old Montgomery Block Building now stands, at the corner of Montgomery and Washington Streets. Although very short of rations and almost losing hope of ever reaching the golden land, it was not destined that she should go astray, as she bore many a name on her list of passengers that was to be felt in moulding the history of that wonderful State—yet unborn—California.

A. A. Bennett.

Aside from the subject of this sketch, there was Dr. Morse, whose name and services are dear to every Odd Fellow both here and in Europe; James Anthony, of the Sacramento *Union;* Jonathan Kittredge, and Capt. John Clark, whose name has long been familiar to land-owners and students of Spanish archives. All of these have passed to their long rest, but there are yet among the living many more who have been prominent in civil or commercial circles, none more so, perhaps, than C. P. Huntington, to whom we owe our railroad system and whose fame is known throughout the civilized world. In commercial circles we find the name of Isaac E. Davis, of Davis & Cowell, James Irvine, B. A. Hendricksen, A. M. and L. M. Starr, and James E. Gordon, of the Gordon Hardware Co., the latter gentleman being Secretary of the Humboldt Association, composed of the surviving passengers of the old ship above referred to.

Having been closely identified with the growth and architectural advancement of our State, this brief biographical sketch of his life will be interesting to the readers of our Journal. Born in Schoharie County, New York, July 26, 1825, of parents whose lineage is traced back to the earlier settlers of New York, he has those sterling qualities that lead to giving exact justice to all, and a steadiness of purpose that no obstacle can daunt or throw aside. Both parents were Quakers in their religious faith and practice.

His father, Dr. Joseph Bennett, wished him to study his profession, but from boyhood he evinced a strong desire to become an architect, and as a primary study in that direction, engaged himself at the early age of sixteen to his brother William, at Stamford, to work as a carpenter and joiner in Delaware County, remaining there two years. From there he returned to his native town, and, under the tutelage of his brother-in-law, Orson Phelps, commenced the study of architecture and carpentry, remaining with him nearly three years. In 1846 he went south, to Montgomery, Alabama, and was there engaged in building the State Capitol. In 1848 he designed and built the Orion Academy, at Orion, Alabama, the Grand Master of Alabama coming from Mobile to assist in laying the corner-stone, the edifice being one of the most imposing structures of its day. From Alabama he came, as before mentioned, to California, arriving here August, 1849, and at once engaged in architecture, contracting and building. In the spring of 1850 he removed to Sacramento, where he remained until he again took up his residence in San Francisco in December, 1876, where he has resided ever since.

In Sacramento he constructed some of the finest buildings of the capital city, among the number being the Odd Fellows Temple, Golden Eagle Hotel, Arcade, County Hospital, and other places of note. He was the State Architect under the administration of Governors Haight and Irwin, at which time he was engaged on the State Capitol, Governor's mansion, prison and work-shops at San Quentin, and also revised and completed the branch State prison, at Folsom. Among the prominent buildings of which he was architect, are the Mechanics' Art College, at Berkeley; the Court Houses of Yolo, Stanislaus, Merced, Tulare, and Kern Counties.

In February, 1883, he associated himself with J. M. Curtis, present Architect of the new City Hall, since which time the firm plans have been adopted for the Court Houses at Santa Rosa, Sonoma County, now in course of construction, at a cost of $80,000, and one at Eureka, Humboldt County, to cost $100,000; also the building of Red Men's Hall, in this city.

Paint Adulterations.

We have repeatedly been asked to give the form of adulterations used in paint mixtures. This we cannot do, as there are by far too many already familiar with the nefarious art, and we do not propose to give information which will either help them by additional points, or which will tend to lead into erring paths those who have not as yet been able to master a knowledge of how to injure themselves and their trade by the use of illegitimate material. Better to keep the standard as pure as possible.

The Frieze.

BY R. H. PRATT.

THE frieze is, undoubtedly, the part of the wall decoration best adapted to ornamentation; it bears the same relation to the wall that a cornice does to a house, or a capital to a column. A frieze should give dignity to the room, and should, therefore, be sufficiently wide to admit of ornament that will not seem cramped or insignificant when seen from the floor. Some friezes look well when a few feet from and on a level with the eye, but when placed at the top of a wall of very ordinary height, their design is lost and the result disappointing. The relative proportion of wall and frieze is a matter of taste; the tendency seems, however, to be toward having them too narrow rather than too wide. It is often said that unless narrow borders are used, the ceiling will be made to appear low. It should be known that a too narrow border or frieze will have the same objectional effect.

Most often the apparent lowering of the ceiling is caused, not by the width of the frieze, but by its color or design being inappropriate to the paper below, or to the furnishing or use of the apartment.

Correct proportion is very important in decoration, and experience has taught that, provided the design and colors be suitable, a wall of 9 feet in height should have a frieze of about 8 or 9 inches in width; if the wall be 10 feet 6 inches or 11 feet, the frieze should be 15 or 18 inches wide. These proportions will be pleasing if the colors are appropriate in the papers and in the friezes. Sometimes there are friezes made that match the wall papers, having the same design and colors; this plan is of rather questionable propriety. The most satisfactory are to be found where the paper and frieze do not match so exactly in color, the frieze being much richer and more pronounced than the paper, and at the same time, there should be the proper harmony or feeling between them.

The mistake is often made of using paper and frieze together that have not the slightest relation to each other; for instance, sometimes a frieze of conventional design above a wall paper whose pattern is naturalistic or flowered or *vice versa*, or some other incongruous arrangement that is anything but decorative.

Where the paper is dark, it is better to have the ground of the frieze lighter than the paper and the colors brighter; in fact, it is very doubtful whether dark colors should ever be used in friezes; it seems proper to use dark and heavy colors for dados, but it seems most appropriate to use light colors or gold for frieze backgrounds.

When the walls are over 10 feet in height, the effect can be much improved by using a narrow band of plain colored paper immediately below the lower edge of the frieze, and let this band be separated from the wall paper below by the picture moulding or other narrow wooden moulding having not much projection. This band of plain paper should be of a tone that is in harmony with the general effect of the paper and frieze, and of about the same intensity of tint as the wall paper.

In most rooms the windows are of such height that their casings project beyond the lower edge of a wide frieze; in cases of this kind when the effect is unsightly, there are two methods of overcoming the difficulty. One plan is to have a narrow shelf placed over each window, either resting on the casing or a little above it, if the space be sufficient; upon this shelf small plaques or vases may be displayed, thus distracting the attention from the frieze, or the curtain pole or valance may be placed nearer the ceiling, and if the window casing show below the pole it may be covered by a valance.

Like other paper hangings, the tendency in many friezes is toward over-crowding, and too much elaboration, which is apt to render them ineffective and feeble. Friezes whose ornament is vertical, or if floral appears to grow toward the ceiling, are well adapted to rooms whose ceilings are not very lofty, for the reason that all ornament or decoration having an upward tendency, adds to the apparent height. Such friezes should be so arranged that the upper part nearest the ceiling should be more open and less crowded than the lower edge.

Avoid growing or vertical friezes whose upper margin or finish is heavy; the upper edge should be like a sky or atmosphere. If, however, the pattern of the frieze be of the scroll or running vine description, the finish on the top and bottom may be equal in width. This kind of frieze is best for large and lofty rooms.

As the frieze has generally as much to do with the appearance of the room as the paper, great care should be used in selecting; recollect that the frieze is not exposed to so bright a light as the wall paper, and, consequently, should be brighter in its color; the ground may be of gold, or of a lighter tint than that of the wall paper. When the paper on the wall is very light and delicate, and it is impossible to have lighter colors in the frieze, let it be on the same ground, but with more pronounced colors, but do not let the colors of your frieze be so prominent as to kill the effect of your wall paper. Do not have the difference so great as to be unpleasant, nor so nearly alike that it is difficult to determine when the frieze begins; it appears as though the paper extended to the cornice or ceiling. If gold be used in the frieze, it is best as a ground and not as a figure. A gold frieze may be used above a paper that is without gold with good effect.—*The Decorator and Furnisher.*

REMOVAL.

Notice the removal of Dunham, Carrigan & Co. to their new quarters, 17 and 19 Beale, and 18, 20, 22 and 24 Main Street. They carry the largest stock of Builders' Hardware of any Firm in the City.

Why Work is Scamped.

THERE are said to be tricks in all trades, and the rule apparently holds good in the house-painter's craft. He has, it appears, two ways of complying with a contract. If the owner of a house personally employs him to put on so many coats of oil and lead color, he will carry out the order exactly without stinting materials; but if the owner entrusts an agent with the business, the house-painter knows that his intermediary will expect a handsome commission, and this must be obtained at the expense of some other person. If the painter pays it out of his own pocket, all his profit will vanish; were he to put the matter to the owner, an *expose* would be certain, with the result that no more business would ever come from that agent. In this dilemma the sorely-driven painter saves himself by doing his work in the cheapest possible way, without giving heed to the terms of the specification. At all events, this was the confession frankly made to us the other day by one of the craft. The man stated specifically that if an owner ordered two coats of oil and lead color to be put on a house, he would faithfully comply; but if the commission came through an agent, one coat of size and one coat of oil and lead would be made to serve the purpose. The agent, of course, would not say anything for fear of having his black mail cut down.

Paste for Paper-Hanging.

BEAT up four pounds of good, white, wheaten flour in cold water—enough to form a stiff batter—sifting the flour first, and beat it well to take out all the lumps. Then add about two ounces of well-powdered alum. Have a quantity of boiling water ready at hand, take it boiling from the fire and pour it gently and quickly over the batter, stirring it rapidly at the same time; and when it is observed to swell and lose the white color of the flour, it is ready for use. The quantities here indicated should make about three-fourths of a pail of solid paste. It is recommended not to use it while hot, as when cool it adheres better and goes further.

A little cold water poured over the top of the mass will prevent the formation of a skin from the drying out of the paste. When about to use, a small additional quantity of cold water should be added, so that the paste will spread easily and quickly under the brush. In warm weather this paste must be used quickly, as it cannot be kept for many days without fermenting and souring, when it becomes thin, watery, and useless. If it be desired to avoid this, the addition of a few drops of carbolic acid to the mass when it is prepared will enable it to be kept almost indefinitely.

STEEL SINKS.

Send to Richards & Snow, 406, 408 Market Street, for a circular containing a full description of these necessary adjuncts to a cleanly kitchen.

A NEW AND VALUABLE BOOK.

"How to Build, Furnish and Decorate."

THIS is the title of a book recently published by a co-operative building plan association, of New York, and which deserves more than a passing notice from the hands of those who appreciate the need of a higher order of architecture, and greater harmony in the furnishing and decoration of a home. It contains the astonishing number of one hundred and twenty-six different plans for buildings, the majority of which are for cheap but tasteful dwellings, such as cottages, villas, and the like, of all conceivable styles of architecture and construction. Many of the views are shown in perspective, enabling one to see just how the building will look. The series of plans occupy only one-half the book. There are about forty pages devoted to furniture and decoration, liberally and handsomely illustrated, following which are over a hundred other designs, embracing barns and other outbuildings, dairy houses, cheese factories, piggeries, aviaries, corn-cribs, poultry sheds and houses, ice houses, summer houses, with a great variety of rustic designs for arbors, lawn baskets, vases, etc.

Landscape gardening is also touched upon, plans being furnished for laying out garden and fruit grounds, making artificial rock-work for fountains, and the construction of hot-beds and green-houses. How to build a cistern is fully described and illustrated. In short, it is probably the most comprehensive work of the kind that has been issued in this country, and its publication must have involved an enormous sum of money.

A supplement to the latest edition contains full and complete blank forms for the most approved form of specification to be used in building, together with blank forms of contract and builder's bond. In connection with the latter, is a blank form for a "bill of quantities," which provides for everything that can enter into the construction of a building, and is divided into "Mason's Estimate," "Carpenter's Work," including materials, "Slater's Work," "Tinner's Work," "Plumber's Work," "Painting," and "Miscellaneous Expenses."

The price of this remarkable Work is only $5.00, and it would be cheap at three times the figure. The publishers of this paper are agents for its sale, and will send it to any address in the United States on receipt of the price.

To Render India-Ink Waterproof.

AS THE ink is prepared with a certain proportion of gelatine, the addition of a little bichromate of potassa, followed by exposure to sunlight, has been recommended for rendering the ink so insoluble in water, that it will not run or spread when water colors are used for shading the sides of the lines.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co's SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING MAY 27, 1884.

299,098.—FAN BLOWER—F. C. Anderton, S. F.

299,330.—PILOT OR WHEEL GUARD—Bennett & Fitch, S. F.

299,331.—WELL PIPE CUTTER—A. W. Benson, San Bernardino, Cal.

299,195.—PLOW—J. A. Bilz, Pleasanton, Cal.

299,208.—LAYING AND SECURING RAILS IN ROAD BEDS OF RAILWAYS.—J. Denechaud, Sr, S. F.

299,211.—DRY SEPARATOR—H. Earhart, Santa Maria, Cal.

299,368.—SEWING MACHINE.—Fisher & Hart, S. F.

299,470.—SELF ADJUSTING PULLEY—W. A. Grondahl, Portland, Or.

299,383.—TAILORS MEASURING DEVICE—J. S. Hand, S. F.

299,226.—DRY CLOSET—T. W. Jackson, S. F.

299,234.—SAFETY GUARD FOR CARS—F. P. H. Loftis, S. F.

299,409.—AMALGAMATING PAN—Geo. H. Malter, S. F.

299,237.—FARM GATE—Chas. W. Mann, Haywards, Cal.

299,238.—WAGON TONGUE SUPPORT—W. P. Martin, Chico, Cal.

299,259.—AMALGAMATOR—Edward Pike, Salt Lake City, U. T.

299,496.—METAL BORING AND SLOTTING MACHINE—J. Richards, S. F.

299,271.—BUCKLE AND RING—Jas. B. Sayre, Sacramento, Cal,

299,186.—WATER JACKET FOR ROTARY PUMPS—A. W. Von Schmidt, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co., in the shortest time possible (by telegraph or otherwise,) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Apprentices' Column.

In reply to a request made last month, by an apprentice, regarding the finding of bevels and cuts for hoppers and lay-back seats, the following is submitted. It is old, but correct and simple. Let Fig. 1 represent a box or hopper whose sides splay; or it may form a bread-tray, or the back and two ends of a wagon or sleigh seat, if we take off one side and cut it off

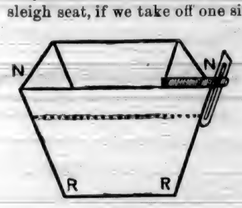

Fig. 1.

Fig. 2

at the dotted line, where a seat would be required. The lines *N R* show the bevel or splay of the box. Take this bevel and transfer it to the end of one piece of the stuff you intend using, as shown at *P*, Fig. 2. Then take the distance *S O*, on the marking gauge, and run a line on the board from *O* to *K*, Fig. 3. Now make the line *A B* the same bevel as the hopper, or, the bevel as now set, may be applied with the stock resting on the edge *R*; then the blade will represent the line *A B*. Square up from *M*, cutting *A R* at *P*, then square over

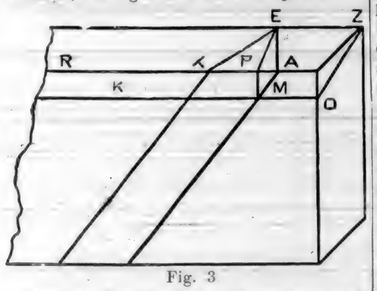

Fig. 3

on the edge the line *P E*. Then connect *A E*, which will be the angle required for a butt-joint, the inside corner being the longest. If it is required to miter the joint, set off the thickness of the stuff as measured at *Z O*, from *A* to *X*, then the line *X E* will be the bevel sought.—*The Builder and Woodworker.*

A Preacher on Hot Boxes.

We heard a preacher in a fashionable uptown church, last Sunday, expounding the advantages to mankind of keeping the Sabbath. As an illustration of how all nature, inanimate as well as animate, required cessation from labor, he said: "Even in traveling with railroad trains, we find that stops have to be made at certain distances to let the axle-boxes get time to cool. The labor of running makes these boxes get hot, and, if their necessity for rest was ignored, they would get red-hot and burn up the train. But the train-men understand the case, and the train is stopped for a time, and, while passengers go out and refresh themselves, the boxes are getting refreshed by rest. They cool down in a few minutes, and then the train can proceed in safety."—*American Machinist.*

Competitive Contracts.

The old saying that "competition is the life of trade," like many old sayings, is a very one-sided expression of truth. It frequently degrades, and sometimes destroys, legitimate trade, instead of promoting it. It implies more or less directly a considerable amount of dishonesty or incompetence lying around, otherwise there would be no occasion for it. Undoubtedly these troublesome defects abound in human nature, and we cannot safely ignore them, but that all our business management should be based upon these sandy foundations is most unfortunate. Competitive examination, tests, and endeavor in many directions, are indispensable, but there are certain points and considerations that should be kept faithfully in view, or competition is but another name for boasting and deceit.

The first essential in an honorable competition, one in which an honorable man would be willing to take part, is that the thing to be done should be clearly understood, not merely by the participants, but by those to whom the results are to be submitted for decision. To ask estimates upon work, the real quality and value of which is not clearly and uniformly understood, is simply absurd. It is random guessing at an unknown quantity. The practice of issuing a general invitation for estimates in open competition is, in most cases, a pernicious one, if not actually dishonorable. By way of safeguard it is customary in such cases to reserve the right to "reject any and all bids." This means, in plain English, that those who are to decide the letting of the contract will not be held as under any obligations to the competitors on account of the amounts presented, and the lowest bidder has no advantage unless his reputation for skill and honesty renders it advisable to give him the contract. As it usually happens that the most reliable builders do not present the lowest figures, the work for which such competitive estimates are made is usually given to the contractor to whom, taking all things into account, those having the matter in charge prefer to intrust it. This comes back very nearly to the same ground that would have been taken if the same contractor had been asked, without further ado, to name the lowest price at which he would be willing to undertake the work.

To ask a man to estimate upon a contract when it is determined beforehand that, by reason of his incompetence or lack of integrity, the work will not be assigned to him, is surely an insult to him and to the other competitors. Yet this appears to be done, and not infrequently, with the sinister purpose of reducing the estimates of those who are esteemed reliable. Especially does the feeling prevail that in all public works everybody should have an opportunity to make proposals, as though public works were a sort of bonanza in which all should have a share. Of course this is nonsense; the right management of public matters being precisely the same as that which a wise, just and far-seeing business man would apply in the conduct of his own.

While there is much that is disheartening to good builders in the usual way of managing contract work, a well-earned reputation for integrity and ability gives far better chances than the smartness that tries to secure an "inside" track by questionable means and the pretense of doing cheap work, which, in the end, is sure to prove the most expensive.—*The Builder.*

Painting is no Expense.

It must be admitted that the Germans, the world over, are celebrated for their industrious habits, thrift and general economy, and they have a maxim that "painting is no expense." This theory, regarded in a comprehensive view, is undoubtedly correct. An occasional coat of paint on the outside of buildings greatly prolongs their durability, and upon a metallic surface prevents corrosion. It is a matter of doubt, however, whether board fences, on account of being exposed on both sides to the wind, and rain and sun, remain in a sound condition longer by receiving an occasional coat of paint. We have seen them not protected by any substance, standing after an existence of fifty years; and in one instance, the board fence—behind which a company of riflemen sought protection when it suddenly fired upon the Hessions engaged in burying the dead, after the close of the battle of Germantown, in the graveyard attached to the present Concord school house, this fence, which was on the ground of the late Peter Keyser, maintained its position, though very thin, with bullet holes worn to four times their original dimensions, seventy-two years after the battle, never having had, we learned, any paint upon it, as in fact, it was of rough cedar boards. How much longer it stood we are not informed.

Frame houses and barns are often painted dark colors, which are preferable to white in this latitude, as they have a tendency to absorb caloric and render the structures warmer than they would be if daubed with a light or white shade. The whitewashing of walls, fences and buildings produces a tone of neatness, but after a heavy rain or two the original faultless color is decidedly marred. Paint is more durable in its nature, and when applied to either buildings or farming utensils well repays the expense, and when they are refreshed by an occasional retouching of paint, it is a very decided benefit in appearance and wear, and we commend, therefore, with confidence, the advantages of painting, agreeing with the Germans that "it is no expense."—*Ex*

MALLEABLE IRON CRESTINGS AND FENCES.

The Phœnix Iron Works of this City are agents for the celebrated Malleable Iron Crestings and Fences. The designs are perfectly original and are very beautiful. Send for circular.

Modern Architectural Designs. $10.00.

A Formula for Calculating Architects' Charges.

That the present five-per-cent rule is inadequate is, I think, evident. The problem is to find a rule which is more flexible, and, therefore, more easily adhered to and more just.

Other things being equal, the value of an architect's services should vary in some direct ratio with the amount of work in the building. Whether this consists of more elaborate decoration, or of more difficult construction, the comparative amount of work in buildings, apart from their size, is more or less closely determined by their cost per cubic foot.

Our first element, then, is this cost, denoted by *R*.

Experiment shows that to determine the ratio we may take the square root of the cost per cubic foot, as follows :—

Cost per cubic foot.	Square root.	Corresponding Building.
10 cents.	3.1 per cent.	Cottage.
15 "	3.9 "	Country House.
25 "	5. "	Apartment House.
35 "	5.9 "	Town House.
50 "	7.1 "	Public Building.

The column headed "corresponding building" is intended to give a very rough idea only of the class of building that costs about so much.

Putting *C* for the architect's charge, the formula now stands :—

$$C = \sqrt{R}.$$

There is another important factor, however, which must not be lost sight of. The larger the building the less it is worth to do the architectural work. That this is naturally and properly so is obvious. So that besides the direct ratio spoken of we have an inverse ratio with the size of the building.

Experimenting as before—the whole thing is purely empirical—we find that the cube root of the cubic contents of a building gives a proper proportion in which to reduce the charge with the size.

Cubic feet.	Cube root.	Inverse Proportional per cent.
50,000	36	5.4
100,000	46	4.2
500,000	80	2.5
1,000,000	100	2.

Introducing this factor of size into the formula, denoting it by *S*, we have :—

$$C = A\frac{\sqrt{R}.}{\sqrt[3]{S}.}$$

As a constant which must be arbitrarily determined, perhaps 50 is a fair value for it:—

$$C = \frac{\sqrt[50]{R}.}{\sqrt[3]{S}.}$$

That is, fifty times the square root of the cost per cubic foot in cents divided by the cube root of the cubic contents will give the proper architect's charge for full service—*C* being obtained as a percentage on the cost as at present.

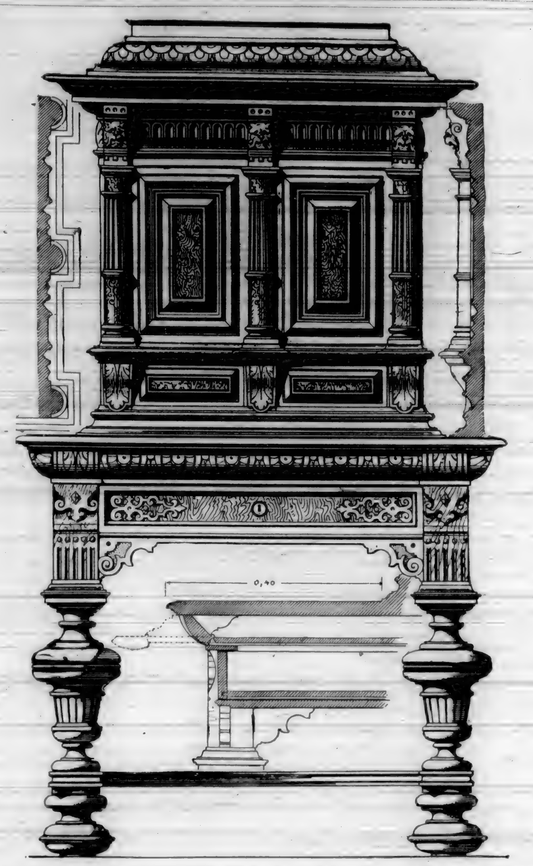
EXAMPLES.

I. Country house, 40 x 30 x 40 = 48,000 cubic feet ; cost, $8,000 = 16.7 cents per cubic foot.

$$C = 50\frac{\sqrt{16.7}}{\sqrt[3]{48000}} = 50\frac{4.08}{36} = 5.66 \text{ per cent.}$$

II. Country house, 40 x 60 x 40 = 96,000 cubic feet ; cost, $16,000 = 16.7 cents per cubic foot.

$$C = 50\frac{\sqrt{16.7}}{\sqrt[3]{96000}} = 50\frac{4.08}{46} = 4.43 \text{ per cent.}$$



III. Country house, 40 x 30 x 40 = 48,000 cubic feet ; cost, $16,000 = 33.4 cents per cubic foot.

$$C = 50\frac{\sqrt{33.4}}{\sqrt[3]{48000}} = 50\frac{5.78}{36} = 8 \text{ per cent.}$$

IV. Town house, 25 x 70 x 60 = 105,000 cubic feet ; cost, $35,000 = 33,3 cents per cubic foot.

$$C = 50\frac{\sqrt{33.3}}{\sqrt[3]{105000}} = 50\frac{5.77}{48} = 6 \text{ per cent.}$$

V. Public Building, 100 x 100 x 100 = 1,000,000 cubic feet ; cost, $500,000 = 50 cents per cubic foot.

$$C = 50\frac{\sqrt{50}}{\sqrt[3]{1000000}} = 50\frac{7.1}{100} = 3.5 \text{ per cent.}$$

John Beverly Robinson.

N. B.—The cost per foot is intended to include all interior decorations that the architect has anything to do with, the separate ten per cent. on such work being abolished.

—*American Architect and Building News.*

Architectural Drawing, $2.50.
Science of Carpentry, $5.00.
Detail Cottage Architecture, $10.00.
Builders' Guide, $2.00.
Drawing and Shading, $1.25.

Many plunger-closets now in use, the *American Architect* remarks, are so constructed as to discharge suddenly into the soil-pipe at each use as much as four and one-half gallons of water. Under certain simple conditions, often met with in practice, such a discharge, even with the soil-pipe properly ventilated at head and foot, will produce an exceedingly powerful draught on the traps of fixture below. It will siphon out a 3½-in. pot-trap in thirteen discharges, or a 4-in. pot-trap in sixteen discharges. It will destroy the seal of a 1½ in. S trap, 1½ inches deep, and having a vent opening at the crown ¾ of an inch in diameter, in seven discharges. If a rubber tube, 9 feet long and three-fourths of an inch inside diameter, is attached to the vent opening, a single discharge will completely empty the trap. An S trap with a 1¼-in. vent opening, to which is attached 16 feet of new 1¼-in. (inside measure) lead pipe, will lose its seal under this test in four discharges.

American House Carpenter, $5.00.
Modern Perspective, $6.00.
Mechanic's Geometry, $5.00.

External Architectural Decoration.

BY A. C. BOND.

THE art public has always had a voice in architectural matters. The influences operating to bring about a change from accepted styles, and the decorations bound up with these, are especially active in periods of transition, finally exerting their force in securing a general concurrence in some special order of development. The new taste created must be gratified, and architects, catching the spirit of the day, move with it. A study of the early architectural works in the clay plains of northern Italy led to the introduction of the *Renaisance* style, with its converging tendencies, and free appropriation of classic forms, with reference to picturesque effect.

We have had a succession of styles—Greek, Roman, Gothic, Louis XIV., Louis XVI., Elizabethan and Queen Anne. The latter two, which largely drew from classic models, often incongruously applied, and with a mannerism of their own, seemed to prepare the way for the *Renaissance*, which, without excluding classic orders, bears evidence of long continuance. Beyond any other style it lends itself to ornament.

Concerning ourselves, with the characteristic features of business structures, we first turn to porticos. As inlets to a building, they are of prime importance. A portico which appears as a mere attachment to a structure, not fairly incorporated with it either as to material, styles or mouldings, is very unsatisfying; still more so if it appropriates rich decorative features of which the *façade* is devoid. We naturally look for imposing porticos of great area and height, and with *façades* richly dressed. They are at once becoming and consistent, but instances exist in which, though exteriorly mostly of the structures they adorn, the value of their decorative features is reduced by arch or lintel, not to speak of pediments, reaching far above the ceiling of a hall, possibly enclosing the windows of a principal apartment; they excite expectations of loftiness in the vestibule which are not realized, deceiving the eye as to inner construction, and to this extent are veritable shams. There is no architectural beauty in want of consistency or in announced inappropriateness. As well-considered porticos we may point to the Welles building, above the Bowling Green, the Williamsburgh City Insurance Co., the United Banks, the Boreel, and Iron and Coal Exchange buildings. The imposing appearance of the majestic portico of the Mutual Life, on the site of the old Post-office, on Nassau Street, and which is of two stories, is due in part to its vast proportions and classic design, and for the rest, to contrast of material and surface, as between polished blocks of granite, hewn granite, and rough stones. Large pieces of granite, with alternate blocks polished and fluted, and two polished granite columns with capitals of modeled leaf-work in Italian marble, support a frieze; the ceiling of this first story of the portico being paneled with richly moulded squares enclosing foliated rosettes. The piers of the second story are of limestone, contrasting well with the granite of the first story, and these are paneled and enriched with elaborate carvings; with these piers are ranged two granite columns, that support an arch with a vaulted paneled ceiling. The capitals of the flanking piers contain heads symbolic of Europe, Asia, Africa, and America.

Our architects, on the whole, use skillfully the freedom afforded by the *Renaissance* style in the treatment of the capitals of columns and pilasters. With greater variety we are getting more expression. In leaf designs they prefer a few stems boldly outlined, a few leaves with serrated edges, and projection of the bell to heighten the effect of the deeply cut moulding, free from unmeaning details.

It has at last been discovered that some of the commonest species of forms are not to be surpassed for elegance and refinement of form. A favorite ornamentation to shafts are bases of foliage, where the effect is obtained by mere contrast of convex and hollow leaves, and these are repeated in many instances on the cornices. There is a vast difference between the mere crowding of leaves on stone, and a style which preserves their most beautiful characteristics. Overwrought decoration is destructive of grandeur. Much is made of boldly projecting stems and concave lobes that yet preserve the form of the leaf.

Scroll work, leaf and foliage in bas-relief on panels, entablatures and friezes, do not alone content our architectural designers, who vary their ornamentation with allegorical monsters, grotesque and flattened visages and heads of animals, entangling also birds in foliage, and suffering reptiles to creep among the leaves of capitals. A monstrous griffin, projected from the angles of what is known in financial circles as "The Fortress," guards the Broadway entrance of Wall Street. All these are, whatever the taste involved, at least welcome variations from monotonous renderings of more generally accepted forms. Included in *façade* mouldings, are medallion heads of individuals in some way identified with the building or its trade purposes; and corporate bodies, raising new structures, are availing themselves of the decoration afforded by corporate seals. Again, artistically designed monograms, in terra cotta or stone carvings, are coming into extensive use to enrich archivalts, architraves, entablatures, or door panels. These monograms are set frequently in floriated tracery, or on a geometric ground with which they unite in mazy, flowing lines, or the lettering is caught up in the tails of foliage or scroll work, or only half revealed.

External expression should be the apt exponent of the purposes of a structure. External as well as internal effect has been considered in all great developments of art. The Washington building, at the foot of Broadway, is typical of the large composite structures that are being erected, of brick, stone, iron, and terra cotta. Lofty pilasters, with projected leaf capitals, rise from above basement story to frieze in reposeful dignity, bearing carved mouldings, in terra cotta, in line with the principal longitudinal bands of terra cotta enrichments that mark off leading divisions of stories. These carvings, running under the tiers of windows, serve directly to ornament them and to emphasize the well-designed chamfers. whilst arches, in recessed brick, surmount them above the line of the capitals. The semi-circular windows, that, resting on corbels, project at the two southern extremities of the structure, are picturesque in the highest degree. The main entrance is a massive iron gate, composed of bars twisted into curved forms, with tapering extremities and apparently forge wrought. What a contrast does such a building offer to the old-style business house, with dingy and coarse brick front, or stone veneered *façade*, stereotyped form of Grecian porch, with windows that were merely apertures, or had only fillets, cap moulds, and possibly keystone panels—the building surmounted with an unpretentious cornice, and a parapet obscured roof.

The Morse building is a prominent example of the capabilities of brick work itself on ornamentation. The simple means by which decorative effects are brought out, whether in the disposition of the bricks or contrast of the simple colors, black and red, is a source of pleasure and gives character to the carefully elaborated design. Any terra cotta decoration is of the least obtrusive character, and has to be searched out. The dressings present, at every point, novel decorative features.

In the building of the National and Manhattan Bank, of New York, the contrast of surface as between the polished granite pilasters of the *façade* and the chiseled surface of oolitic stones, besides pleasing in itself, brings the pilasters out in fuller relief. This is one of

the most costly, as well as one of the most ornate, of recent erections, and compels admiration for the converging tendency of the design, the eye being carried up to the loftily-placed range of pilasters above the main cornice, repeating, in closer rank and in miniature, the forms of those below, and crowned by a pediment.

Occasionally we meet with an excess of ornament in a *façade*, in the form of panels, architrave, string-courses and heads of windows—an excess interfering with that repose which is so essential a condition for gratification. The *façade* of the Park Bank is one mass of ornamentation, unbalanced by sufficient wall space; the upper portion of Union Building is confusing and repelling, ignoring the main constructive lines, being hid by pretentious mouldings. Ornamentation, at the best, is but a subordinate feature.

The arrangement of decorated wall spaces is a great point is securing a good *façade*, such as will present enrichments to best advantage. In certain late erections may be seen two upper intermediate stories, almost wholly bare of mouldings, in order to heighten the effect of entablatures, cornices, capitals, and other ornamentations above and below. In a number of elaborated *façades*, the pilasters space off the height of two stories, which make leading deviations through a springing arch, ordinarily moulded between pilasters or piers, thus crowning the groups of windows enclosed.

In the Lincoln Safe Deposit building, the first story of stone is comparatively plain, whilst the second, containing the offices, has particularly rich mouldings. A mezzonine story answers the effect of a balcony, such as is seen in an Italian structure. From the balcony, the stories above the arches are more elaborate than the lower ones. Not only are longitudinal bands of enrichment made to differ, but a different form is frequently given to the separate tiers of windows, with excellent results.

With the loftier buildings now erected, the old dictum, that the ornament of a *façade* should increase with its assent, loses its force; for elaborate ornaments to be fully effective, must be seen. The terra cotta entablature of the Produce Exchange, with its floriated enrichments, distributed between the spans of the arches of the principal tiers of windows, including the arms of States, would have been a confused medley if elevated toward the principal frieze.

It might be well if architects, who indulge their proclivities for tower-like elevations, sometimes as in the case of Temple Court, crowning thereby pointed roofs, would bethink themselves of enlivening the sky-line with gilded weather-cocks, which have always a life-like aspect, and would appropriately constitute an aerial vanishing point. Chaucer, mindful of their appropriateness, wrote:—

"The towers hie full playsante shal ye finde,
With fanes fresh tuned turning with every winde."

WHAT IS DUE THE ARCHITECT.—*Building*, of New York, has in its May number an article on the relations of architects to the owner of property to be improved. The article upholds the right of the architects to just compensation for all services rendered, and deprecates placing him on the same plane as the contractor or material man. It says: "The true view of the relation that should exist between the architect, owner, contractor and the men who furnish material, can be set forth in a few words. An architect is the agent of the owner—his confidential agent. It is his duty to stand between the owner and the contractors and the material men. In every natural contest with the builder (a contest that is inevitable while human nature remains as it is), the architect should naturally be found on the side of the owner, whose interests he is engaged to protect. Owners should reflect that if they go to architects who work for low commissions, they do not save anything in the end. The chances are that heavy discounts, which should accrue to them, go to help swell the low commission, in addition to which the contractor very likely has levied a commission on the work that he pays to the architect. What a contractor pays an architect, aside from the *morale* of the latter's receiving it, is bad for the owner because it must come from the work itself."

THE DOOMED CHESTNUT.—A Scientific authority claims that the chestnut tree, which is disappearing so rapidly, has a fixed period of evolution. This tree, like all others of the spongy inferior fibre, cannot flourish before the close-fibred trees, such as the oak. In ancient times a rank, quick growth covered the earth, which yielded, as the ages went, to the stouter trees. Thus it is the chestnut is doomed in the operation of the same law.

Wheeler's Patent Wood Filler.

WE notice in recently issued copies of specifications prepared by various architects, that the above Filler is called for in the proper place, thus assuring the general public that it has become a standard preparation. We can indorse this Filler as one of the very best yet brought to our notice. It is kept by every dealer in paints and oils throughout the Pacific Coast.

Nineteenth Industrial Exhibition of the Mechanics' Institute.

WE have received the preliminary announcement of the Fair to be held under the auspices of the above named institution. From the circular received we glean the following facts:—

The Fair will be held in the building owned by the Institute on the block bounded by Hayes, Grove, Larkin and Polk.

It will open August 5th, and close September 6th. Premiums of Gold, Silver and Bronze Medals, as well as cash, will be offered as set forth in the Premium List.

Seven thousand five hundred feet of additional space will be added to the main floor for the display of machinery. It is intended to make this department one of the distinctive attractions.

A grand fountain and cascade of original design thirty feet in height, will be erected in the center of the main nave.

Art galleries are to be remodeled and improved in regard to natural light, and it is intended that the display of home and foreign artists will far exceed anything ever before seen in this city.

Each afternoon and evening a grand instrumental concert will be given by the best musical talent on the coast.

Ample steam and water-power will be furnished free.

It will be seen from the above that the managers are determined to do all in their power to make the present Fair the most successful that has, as yet, been held by the Institute.

We would especially call the attention of manufacturers, inventors, artists, farmers, merchants, producers and dealers in goods, wares and merchandise of every description, to the advantages offered by this opportunity to display their various articles, so that they will be seen by a larger number of people than they could possibly be by any other arrangement.

To all exhibitors we would say, HAVE YOUR SPACES FILLED AND FULLY ARRANGED ON THE OPENING NIGHT. Any information will be cheerfully given by the Secretary, J. H. Culver, 31 Post Street, S. F.

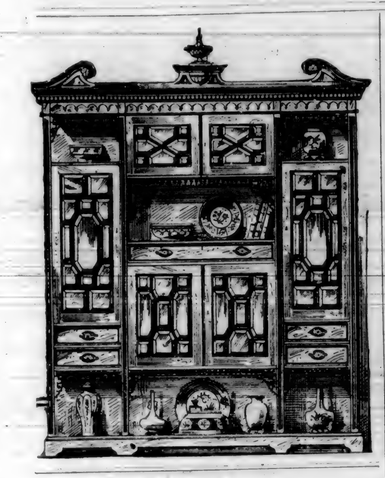
"Manual for Furniture Men."

A NEW WORK.

THIS book contains hints and practical information for cabinet makers, upholsterers, and furniture men generally. Also a description of all kinds of furnishing with full directions therefor; varnishes, polishes, stains for woods, dyes for woods, gilding for silvering, receipts for the factory, lacquers, pictures, engravings, etc.

This work will be found to be of great help to the class mentioned, and its price has been kept down to such a point as will not be beyond the means of the average workingman.

Sent post-paid to any address upon receipt of ONE DOLLAR.



Building Contract.

S sued B for $492.60, the balance due him for building a two-story brick house, and B made a counter claim for defective material thrown out, and money expended in repairing the unskillful work of S. The contract price was $2,535, and the plaintiff had been paid $2,042.40; the counter claim was $1,985, which the defendant got a judgment for. The defense to the counter claim was a most novel one: That the plaintiff had "no experience in laying foundations, as the defendant knew." The case - Sherman *vs.* Bates—was carried to the Supreme Court of Nebraska, where the judgment was affirmed. Judge Maxwell, in the opinion, said: "A party entering into a contract to construct a building thereby agrees that all parts of the structure shall be put up according to the agreement. As a defense to inferior workmanship he cannot say, 'I am not a mason, or a carpenter, or a tinsmith; therefore I am not liable for defects caused by unskillful or careless workmen.' The question is not one of skill on the part of the contractor, but of compliance with the contract. If a contractor agreed to erect a building in a certain manner, he must comply with the agreement, and no plea of a lack of skill of himself or any of his workmen or sub-contractors will constitute a defense for a failure to comply with the contract."

BUILDING SUPERINTENDENCE.

A NEW WORK AT A NEW PRICE.

This work has been quoted in our columns at $4.00. The price should have been $3.00. All the books kept on hand by us are marked at Publishers Prices. Those who have paid us $4.00 for a copy of this new work can have the extra $1.00 returned by sending us their address. A copy will be sent to any address upon receipt of THREE DOLLARS.

Drawing for Carpenters, $1.75.

Building Superintendence, $4.00.

How to Boil Linseed Oil.

THE *Carriage Monthly* gives the following directions, which may be of service to some of our readers: First, be sure that you have the pure linseed oil. There is much sold as such manufactured out of peanuts. The test is simple. Nut oil has a sharp, acid taste, smells just like sour peanuts, is darker and thicker than the other oil, has a clinging tendency when rubbed on the finger, dries with a gloss even in priming coats, and is very much given to gumming up when sanded. Pure linseed oil has a bright amber color, runs freely, sparkles when flowing from the can, tastes smooth and mild, and has the smell of a flaxseed poultice. When you are satisfied that you have the genuine oil, and wish to boil it thoroughly, first take, say, about ½ pound of red lead and the same quantity of sugar of lead; put into 5 gallons of the oil, and place over a slow fire, so as to boil evenly. Do not let your fire get either too hot or too low; keep an even temperature if possible; coke or charcoal is preferable to either hard or soft stonecoal. Avoid a wood fire, as, after the oil gets to boiling heat, a sudden flame shooting up might ignite the entire lot. Let it boil seven hours full; the red lead and sugar of lead will then become dark brown. Stir all the time while boiling slowly, and only one way; do not change the direction of the stroke or you will burn the oil, just as you would starch. After you have taken it from the fire, cover it up and let it stand to cool off, say, over night. The sediment will settle; pour out the oil and strain; your oil is boiled, and a better article you could not have, as all the fatty substances are destroyed. This is the English method, used in all the carriage factories in the United Kingdom.

Sawdust in Plastering.

TWO WESTERN inventors have recently obtained patents for the use of sawdust, instead of sand, in plastering compositions, and this, it is conceived, may be a matter of considerable importance to the owners of sawmills in the principal lumbering towns. One of the patents is for the use of nearly equal parts of plaster-of-Paris, or cement, and sawdust, with the ordinary amount of plastering hair and water; the other calls for the use of about 4½ pounds each of slaked lime and sawdust to one pound of plaster-of-Paris, a quarter of a pound of glue, and a sixteenth of a pound of glycerine, with plasterer's hair. Whether or not either of these described plasters would be cheaper than those made in the ordinary way, they would certainly be lighter, and it is believed that they would better adhere to the walls, and not be so liable to chip, scale, and crack. Sifted sawdust has before been used to some extent, by experienced workmen, for mixing with mortar for plastering external walls, exposed to the alternate action of water and frost, as a preventive of scaling. Certainly the experiment of introducing sawdust in place of sand in mortar is worth trying, for in many places, sharp sand, suitable for the purpose, is difficult to obtain.

Superiority of Country Workmen.

THE *Scientific American* calls attention in a recent number to the superiority of the workmen trained in small machine shops and factories over those bred in larger establishments, where the division of labor, and limitation of the responsibility of individuals, prevent the development of that self-reliance and ingenuity in overcoming difficulties which those compelled to make the most of imperfect tools and to turn their hands to a variety of work, are constantly obliged to exercise. For this reason, the mechanic who has learned his trade in a shop where only two or three men were employed is generally very welcome in the larger ones. Although the costly machine-tools of the great establishments are new to him, and some time may pass before he learns to use them properly, he generally succeeds at last in understanding them far more thoroughly than those who have not been accustomed, by the invention of homely makeshifts, and contrivances for using common tools in unusual ways, to acquaint themselves with the properties and capabilities of the parts which they find combined in a new form. Most architects have probably had occasion to make the same remark in regard to builders' men. The man from the small shop, particularly in the country, is commonly quick, ingenious and reliable. He may in some instances be less skillful with his tools than the city workman, who is not obliged, like him, to turn to other employment during a large part of the year; but he more than makes up for that in his better mental development, which enables him to enter into the ideas of the architect, and to seize opportunities for advancing or improving the work, which his plodding brother from the great shops would not see or care for.

Burning Sewer Gas.

THE Chicago *Tribune* contains an account of what it considers to be a novel method of disposing of sewer gas—namely, the burning it in the furnace of the steam-boilers of a factory. The reporter states that he saw the natural sewer gas burn at the end of the pipe connected with the sewer for nearly ten minutes without a flicker. The Chicago Gas Company, which has pipes in that vicinity, had better have them examined.

This method of disposing of offensive gases from sewers is one that has been many times suggested and in a few cases tried. In exceptional cases it may serve to dispose of a local nuisance, but it is not generally applicable, as is well known to all who are acquainted with the experiments made in London on this subject by competent engineers.

Where there is a leaky gas-pipe in the vicinity of a sewer, the air of that sewer may contain combustible elements, but in this case there is usually an explosive mixture formed; and this is the true explanation of the majority of the explosions which are said to be due to sewer gas.—*The Sanitary Engineer.*

MASONS' and BUILDERS' EXCHANGE OF SAN FRANCISCO,

Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

A full assortment of

SASH WEIGHTS

Constantly on hand and made to order in any shape or style; also weights for Dumb Waiters, Elevators, &c., &c.

ALL KINDS OF VENTILTORS

In Stock and Made to Order

MECHANICS should remember that it is for their interest to forward items of general interest to the publishers of this Journal as, by so doing, they reap much benefit from an interchange of ideas. If engravings are necessary to explain your ideas, send a rough sketch of the same and we will put them in a presentable form.

THE PAINTER'S FOREMAN.

A BOOK OF VALUABLE RECEIPTS.

It explains how to grain or imitate French Walnut that cannot be discounted: also Black Walnut, Oak, Ash, Chestnut Cherry, Satinwood, Bird's Eye, and Curly Maple, and the different woods that are imitated by graining. It gives you a sample color of the different kinds of background used to imitate the different kinds of wood, how to mix and what colors to use to make them, and how to apply them from the first coat to the last.

The graining department is explained so clearly and fully that by following the directions any one can do a first-class job of graining. It also explains how to do different kinds of Fresco work, what colors to use, how to mix and apply them. How to grain or imitate the different marbles, what colors to use, how to mix and apply them. How to make the different kinds of wood fillers, the different kinds of oil finish, the different kinds of polishes. How to gild letters on wood. How to make and use smalt. How to paint banners, etc. How to gild on japan, tin signs. How to make changeable signs that will read three different ways on same board. How to letter glass signs. How to do pearl work. How to gild on glass. How to color glass. How to ebonize wood. How to make paint for school blackboards, etc., etc., etc.

In fact, it is the only work published that explains fully and clearly the different secrets of the painting art.

Price, by mail, post-paid $2.00.

TERMS:

PER ANNUM $2.00 IN ADVANCE

ENTERED AT POST-OFFICE AS SECOND CLASS MATTER.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.
Back Cover, outside, each insertion, $2.00 per square.
Page preceding reading matter, $1.75 per square.
Page following reading matter, $1.50 per square,
Inside Pages, each insertion, $1.00 per square.
Full Page, inside, one insertion, $40.00.
Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

A Fine Showing for June.

JUNE is generally regarded as a quiet month in building activities, but from the summary of our building intelligence, the month just past has been an exceptionally active one in regard to the number and value of contracts let. We find during the month

EIGHTY-SEVEN BUILDINGS OF THE VALUE OF $663,909,

Have been commenced. This amount does not include several upon which work has been started, the most notable exception being the Murphy Building on corner of Market and Jones Streets. As only a portion of the contracts have been let, we refrain from quoting the same until we can give definite cost. From present appearances, the value of building improvements for 1884, will exceed any year of which records have been kept.

Our Illustrations.

THE fine four-page engraving presents an accurate illustration of the New Odd Fellows' Hall. Its cost will be about $300,000. Wright & Sanders, architects.

The elevation and plans for a country residence recommend themselves to those who want a neat, but yet attractive, country residence.

In our next issue we will present the first of our competition plans, the plates of which were not ready for this issue.

San Francisco Chapter, American Institute of Architects.

THE regular meeting of the Chapter was held on Friday evening, July 11th. President John Wright in the Chair.

The following amendment to the By-laws was proposed: In Article XI, Sec. 1, the word "three" be changed so as to read "five," the object being to have five Trustees instead of three.

(This change is necessary on account of the State Law requiring the number of Trustees in an incorporated body to be not less than five. ED.)

Mr. A. A. Bennett was unanimously elected a member as a Fellow.

F. Marion Wells was proposed as an honorary member of the Chapter. Referred to Messrs. Pissis, Curlett & Whittemore as a committee to report at next meeting.

Various bills were ordered to be paid.

Adjourned.

SPECIAL NOTICE TO MEMBERS OF THE CHAPTER.

At the next regular meeting of the Chapter, to be held on Friday evening, August 1,

NOMINATION OF OFFICERS

For the ensuing year will be in order. It is earnestly hoped that all members will so regulate their affairs, that they can be present at the August meeting.

Carmel Mission Church.

THE attention of our readers is directed to the *Editorial Correspondence* — as given below—in which will be found a statement concerning the *virtual destruction* of a very large proportion of the *primitive ideas* of architecture and construction as practiced by the Pilgrim Fathers to the Pacific Coast, in the erection in the valley of Carmelo, near the shores of the bay bearing that name, of the church edifice, which, in its primitive periods, stood alone in that vast wilderness—at that time scarcely known even to the best informed of civilized people, where the untutored and semi-savage tribes of Indians and herdsmen alone entered its portals as devotees—until by the events of time and nature, those who there first chanted the praises of the Most High, and their successors in the order of their existence, together with the humble worshipers who assembled within the sacred walls of the old sanctuary, have passed away, and the sacred edifice itself yielded to the waste and wear of the elements, until its ruins only remained as a relic of what was once the temple of worship.

The many interesting facts surrounding the history of this old mission churches and the devoted men who laid its foundations, and whose earthly remains lie entombed within its walls, has made it one of very extended and general interest; and anything that may be done, which in any unnecessary manner is calculated to mar or destroy the original, will be looked upon with sorrow and regret by all those who venerate the monuments of history.

Editorial Correspondence.

SAN JOSE, Cal., July 8, 1884.

DURING our fourteen days' ramble through parts of Monterey, Santa Cruz, and Santa Clara Counties, we have met with nothing of more than ordinary interest.

AT HOTEL DEL MONTE, our stay was pleasant, and the usual conditions of comfort, elegance and high prices prevailed. There was a goodly number of guests present, but nothing approximating a crowded condition of things during the month of June, although a large increase is anticipated for July.

AT THE TOWN OF MONTEREY, the spirit of non-progression, apathy, and lack of enterprise,

which for so many years has held that place at a stand-still, was clearly manifest on every hand, and seems to satisfy the people of that ancient burgh. Nothing of a "public-spirited" nature is to be seen, calculated to improve general conditions or make the place inviting to strangers, nor of a character to induce investment by outsiders who might be willing to enter, invest, and occupy almost anywhere, where appearances indicate a disposition on the part of the earlier settlers, to make the most of the place itself, and the regions around and about the place of their settlement.

In the matter of building improvements, but little is to be seen. Two one-story stone erections on the principal throughfare is all that we noticed within the town proper, and nothing in the way of constructions was discernable anywhere in the adjacencies. In our survey of the surroundings, we summed up the probabilities to be, that twenty mechanics—all classes included—carpenters, masons, painters, plasterers, etc., would be a sufficient force for all the mechanical requirements in the building line the year through. It is singular how permanently and effectually, even business men may lose sight of their best interests, and permit advantages to flit by unimproved, or wither under the influence of inaction. Yet it is a thing of common occurrence, and Monterey is a striking illustration; while at the same time this one thing is certain, that in the hands of active, enterprising men, Monterey might be made a beautiful, thriving, and prosperous place, and the number of its inhabitants increased five-fold.

Since penning the above, we have sought further information in reference to the causes which produce the state of things existing in immediate proximity to the spot where to-day stands the white cross, on which is inscribed "June 3, 1770," commemorative of the landing of the pioneer missionaries on the shores of Monterey Bay, more than one hundred and fourteen years ago, and find it to be the same that has, in times gone by, so disastrously affected and hindered the prosperity of almost every town and city in the State of California, to wit: Spanish or Mexican Grants, and imperfect titles, and ownership of valuable pieces and blocks, by one or more, and in some cases, by whole families of indolent, stupid, ignorant Mexicans, who do not, and cannot be made to understand that their retirement from ownership would be a public benefit and a blessing to Monterey.

At Pacific Grove Retreat we spent four pleasant, quiet days. The quiet of this—capable of being made—beautiful retreat, is most enjoyable, shutting out, as it does, all the noise, bustle, and turmoil of busy life; but the religious restrictions and restraints enforced are calculated to greatly lessen the number of visitors, and restrict patronage to those only of very moral, or decidedly reverential turn of mind Very wisely, the sale of spirituous liquors, gambling, and all immoral practices are prohibited, but with these, all other means of harmless, social amusements are proscribed such as a properly conducted billiard room, in which mothers and children, as well as fathers and brothers, might engage in the pastime of innocent amusement with the balls and cue—and many other means of enjoyment, which, if permitted and introduced, would greatly multiply the pleasures of visitors, without violation of any reasonably high standard of morals, and approaching sufficiently near to a religious state for all practical purposes.

The closing down of the gates upon all business affairs on Sundays would be consistent with the general character of the place, were it absolute and complete. But its partial enforcement, closing the butcher shop, grocery store, etc., and beaching or tying up of boats, yachts, etc., and shutting off all manner of worldly pleasures, other than as each for himself may improvise, while the business office of the concern is kept open, coaches and teams owned by the management run all Sabbath day for the conveyance of visitors to and from the cars and grove, and in and out, to and from town, for the pleasure of guests, and other things done, yielding profit and pay, at least suggests a degree of inconsistency, which is not removed by the claim that "these things are necessary."

Within the past two years there have been some improvements made, noticeably the restaurant which is well conducted, clean and well lighted and ventilated, although the innovation upon common custom in city life, of dinner at noon, and supper the evening meal, with but a plain, moderate bill of fare throughout, instead of luncheon at noon, followed by dinner at evening, is an arrangement subject to the likes and dislikes of patrons, to please all of whom would be an impossibility.

The thousand and one great possibilities within the surroundings of Pacific Grove, will some day, when the present management shall have ceased, and the interest passed to the control of others of broader and more practical and progressive views, become one of the most desirable sea-side resorts upon the shores of the Pacific Ocean.

Carmel Mission Church. This old historical, by many, venerated, relic of the first works of the devoted men who landed upon the shores of Carmelo Bay, more than a century ago, is passing through changes at the hands of a gang of mechanics, but little less than sacrilegious. The judgment displayed in the restoration of the building is exceedingly bad in many particulars, especially and most condemnably so in the new roof, which obliterates all vestiges and semblance of the original, and substitutes a very steep pitched, pointed modern style of roof, as seen in Catholic, Episcopalian, and other Gothic chapels of the present day; and so in contrast with the style and character of the primitive roof and building, as to change the feeling of awe and veneration which pervaded the minds of those who visited the sacred edifice, to that of disappointment and displeasure at the mongrel attempt to resuscitate and restore the relics of past ages, by the use of the latest inventions of the present day. The sharpening of the pitch of the new roof necessarily raised the apex some eight feet or more above the old, thus giving the front a pointed, modernized air, altogether at variance with the antiquity of the edifice, and so far changing general effect, both in outside and inside appearances, that no one who has formed their ideas from photographic views, nor those who have heretofore visited the sacred place in its primitive ruins, would recognize it as Carmel Mission Church, as far as the roof exterior and interior is concerned. Other obliterations of original features are being unwisely and unpardonably practiced, and the alterations generally shaped to conform much more to present notions of things, than to retain that which was of greater interest—the features incorporated and established by the fathers who laid the foundation, and completed the edifice long before present generations had an existence.

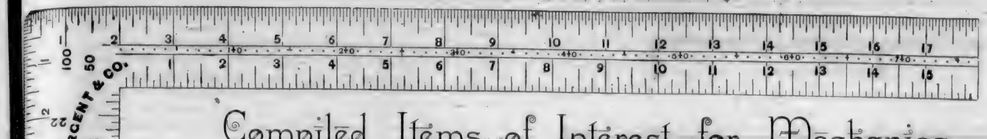
The work being done is of a very cheap and inexpensive character, the total cost of which should not reach $10,000, as far as the restoration work is concerned; and whatever greater amount of money is raised in answer to the efforts being made by citizens to collect funds, its appropriation must extend to other purposes than that of reconstructing the old Carmel Mission Church.

Santa Cruz, to us, one of the garden spots of California, with its splendid sea beach, its magnificent drives over well-graded roads, through scenery of surpassing grandeur, its far-stretching landscapes of valleys, hills, and mountains, together with its numerous other tributary features of interest, is a place where one may dwell for a season at least, in contentment and pleasure.

The whole aspect of affairs present the appearance of general prosperity. A fair degree of building activity exists, in the erection of dwellings and business places. The style of architecture adopted is neat, without any pretentions to great elaboration. From information gathered from various intelligent sources, we are warranted in saying that Santa Cruz and its surrounding country assumes an enviable position among the most favored places outside of San Francisco.

At San Jose, which we reached on the 4th inst., all was life and excitement, with signs of prosperity on every hand, both in and out of town. For notwithstanding the damaging late rains of the season, the losses in hay, cherries, and other things supposed to be badly injured, appear to be so far compensated by gains and advantages in other regards that orchardists and farmers feel confident that the results of the season's ingatherings and returns will be satisfactory.

In building operations, a moderate degree of activities prevail. During the earlier part of the present season, a comparatively large number of buildings were commenced, which gave employment to all classes of mechanics, but with the approach of harvest time, which necessarily attracted the interest and means of both farmers and merchants, the building improvements have received less attention, and a moderate condition of things is likely to continue until the field, orchard, and vineyard interests are in and cared for.



Compiled Items of Interest for Mechanics.

How to Imitate French Walnut.

Mix and coat up the work to be grained the same as for black walnut, using Chromo yellow for coloring. When the background is perfectly dry, take a tablespoonful of lamp-black, mix this in a dish that is free from grease, using beer to mix it with; mix so it is as thick as molasses; saturate a small piece of sponge with this; also mix some dry burnt senna in another dish the same, and saturate another piece of sponge with it; also saturate a larger piece of sponge with beer alone; squeeze this out as dry as you can with your hands; now, give the work a coat of Vandyke brown, mixed with beer; while this is wet, take your beer sponge and dab it over the work until it appears dappled; now, take your lamp-black sponge, and in places make little knots or burls, also the same with your red sponge; do not get too much of the red and black on, as it will make the work appear dauby; now, with your badger hair blender, blend the work softly until dry, blending one way across the panel; when dry go over the work with oil and Japan dryer; while this is green you can throw in it the little veins that are found in the natural wood, by using the black walnut graining color and a flat brush; when dry, varnish.

Changeable Signs.

Make a wooden sign in the usual manner, and have a projecting moulding around it that projects one inch out from the face of the sign; now cut thin grooves into the moulding, one inch apart, allowing each cut to reach to the surface of the sign; in each of these grooves insert strips of tin, one inch wide, and long enough to reach across the sign board; when so arranged take out the strips of tin, and place them edge to edge on a level surface; paint any desired words on their united surface; when dry reverse them and paint other words on the other side; now finish your lettering as usual on the sign board; now put the thin strips in correct order in the grooves; this will complete a sign that will read three different ways.

Paints for School Blackboards.

Common glue, four oz., flour of emery, three oz., and lampblack enough to give an inky color to the preparation. Dissolve the glue in ¾ of a quart of warm water; put in the lamp-black and emery; stir until there are no lumps; then apply to the board with a woolen rag, smoothly rolled; three coats are sufficient.

The Painter's Foreman.

The above three articles are from a new work just issued, entitled the "Painter's Foreman." It is the only work published that explains fully and clearly the different secrets of the painting art. Price, $2,00.

A consignment of this work is now on the way, and we will be able to furnish any one desiring the same at regular publisher's price, viz.: $2.00.

Cummings' Architectural Details **$6.00**

Varnishing Marble Paper on Ceiling.—Before commencing to varnish a paper you must give the same one or two coats of weak size, made from glue, being careful to touch every part, or it will show greasy. When dry it is ready for varnish. If a white paper, the glue must be clear, or it will tint the paper. All paper will not varnish.

Cottages and Villas **$6.00**

Painting on Zinc.—This is facilitated by employing a mordant of one quart of chloride of copper, one of nitrate of copper, and one of sal ammoniac, dissolved in sixty-four parts of water. To this mixture add one part of commercial hydrochloric acid. This is brushed over the zinc and dries a dull gray color in twelve to twenty-four hours; paint adhering perfectly to the surface thus formed.

Church Architecture **$4.00**

Timber can be toughened in seasoning by thoroughly impregnating the same with creosote or coal tar.

Street, Store and Bank Fronts, $4.00
Universal Assistant **$2.50**
Practical Carpentry **$1.00**

Sponges can be bleached to a very pure white by immersing them, after being thoroughly cleaned of sand and dirt, in a solution of one part of permanganate of potash in 100 parts of water, then washing them in water, squeezing them dry, and afterward steeping them fifteen minutes in a solution made by dissolving eight ounces of hyposulphite of sodium and one ounce oxalic acid in a gallon of water. On being washed clean they will be found to be white.

Wooden and Brick Buildings ... **$18.00**
Modern Perspective **$6.00**

Bancroft's Histories.

This magnificent work embraces a complete history of the Pacific States. The territory covered is the western half of North America, from Panama to Alaska, including all of Central America and Mexico, and is equivalent in area to one-twelfth of the earth's surface.

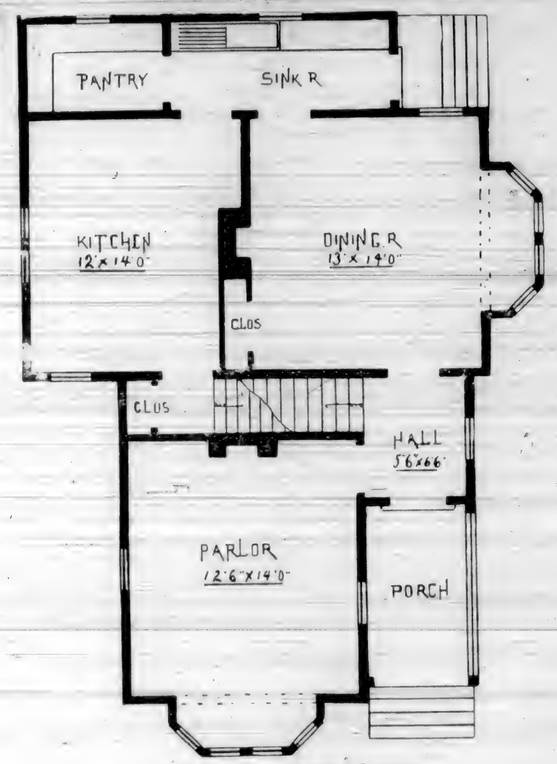
There are to be thirty-nine octavo volumes, with maps and illustrations, fifteen of which are now ready. They will be well printed on good paper neatly and substantially bound, uniform in style, and will average over 700 pages each. Three or four new volumes per annum will appear until the entire series is completed. Subscribers will not be obliged to take the work unless it corresponds with the description in every particular.

	Per Volume.
Bound in Extra, English Cloth, neat and attractive style	$4 50
Bound in fine leather, Library Style	5 50
Bound in half calf, half Russia, or half Morocco	8 00
Bound in Russia Leather or Tree Calf	10 00

Any information in regard to the above will be given by addressing the office of this Journal.

Builder's Guide **$2.00**

Mechanics should remember that it is for their interest to forward items of general interest to the publishers of this Journal, as, by so doing, they reap much benefit from an interchange of ideas. If engravings are necessary to explain your ideas, send a rough sketch of the same and we will put them in a presentable form.



First Story Plan of Country Residence.

Wood Pulp.

It seems that this monopoly has had sufficient rest, and the subject should be discussed at greater length, as in our last article we merely gave a few hints concerning the transformation of wood into paper. Since then, however, we have made an extended visit—a professional one—to one of the largest concerns of this kind in the world, and, though not feeling disposed to mention names, for fear of the article being termed a write up, we will mention what we saw, and view the process from a technical stand-point.

First of all, the wood is cleverly deprived of its epidermis—here we detected a waste which is to be utilized in the future—and, though poplar is the principal timber used, we can find considerable bass-wood and a few sticks of soft maple in nearly every pile. The operation of transforming wood into paper can, with propriety, be divided into three processes, the first of which is purely a mechanical one of making the wood fine. Some mills do this by means of cutters acting on the principle of a planer, but the larger establishments are supplied with grinders which operate across the grain of the stick, reducing it to a pulpy like mass. This is much the better process, though the old way of chipping has many champions. After the wood is reduced to the required degree of fineness, the chips, or pulp, is put in the digesters, which consists of upright boilers, from six to ten feet in height, according to the depth of the first story of the building in which the operation is carried on. Under these large boilers, or "digesters," are the furnaces, while above and behind them are situated the alkali vessels, made of iron, which contains strong caustic soda. Each of these alkali tanks is supplied with the proper fixtures for regulating the flow of the liquor, in which the wood is subsequently boiled, or "digested."

When one of these digesters is ready for its charge, the top is removed, the faucet in the alkali pipe opened, allowing the alkali to flow in the digester and become thoroughly mixed with the wood as it is being put in. When the digester is filled in this manner, the faucet is turned to stop the flow of alkali, the top of the digester is replaced and firmly fastened by stirrups. Fire being applied, the entire mass is soon boiling vigorously, but the steam pressure is allowed to reach 100 pounds only. In this manner the wood is reduced to a pulp as soft as the finest jelly, every observable trace of its original appearance having disappeared. When this process has been carried to sufficient length, the contents are blown off into strong iron tanks with a capacity of withstanding with safety the pressure of the digester's steam. Then the pulp cars, which are simply large vats, receive the mass. These are supplied with perforated bottoms, and mounted on wheels, each car having a capacity equalling that of the tank adjoining. The surplus liquor is strained off into receiving tanks, and the pulp is treated to clear water, which is allowed to flow through it until all traces of the soda are removed. Every particle of soda is reclaimed and re-used in another batch. These pulp cars or tanks are now run out on turn-tables, from which they are taken to the tanks to be thoroughly mixed with clear water, which is done in a properly constructed mixing box. From here it is run into pulp dressers, where every bit of undigested wood is separated from the rest by fitters. From the dressers it comes in the form of large sheets, and is immediately torn up and thrown into the bleaching engines, where, through the action of chlorine—in one factory made from the smoke—it is freed from every particle of coloring matter, and left creamy white.

At another establishment, nearly all these conveyances are dispensed with, the mass being pumped through pipe lines from one place to another as needed, one factory transporting in this way from one building to another, some of which are ower three miles from the rest.

At this stage the process is virtually complete. From the bleaching engine the pulp is run into the drainers—large reservoirs in the basement, where all traces of chlorine are washed out. Thrown out with these, the pulp is once more mixed up with clear water, and after passing thrugh a second set of pulp-dressers is run through an eighty-four-inch cylinder machine, and over nineteen driers, which convert it into a strong, thin sheet, resembling blotting paper, except the surface is harder and smoother. From the driers it is wound on a long reel, and from the latter it passes between knives that divide it longitudinally into three strips, each of which is wound on a cylinder into a roll of about 118 pounds weight. This roll is now done up in heavy wrapping paper, and in this manner is shipped to the dealers or consumers. Some of our larger dailies buy direct from the factory, one mill in northern New York being kept running constantly to supply the editions of the *Times* of the American metropolis.

As this industry grew in importance, competition sprung up, and, of course, the cost of making the paper had to be reduced, and the process of reclaiming the chemicals was investigated, and now is a very interesting operation, as also the making of caustic soda.

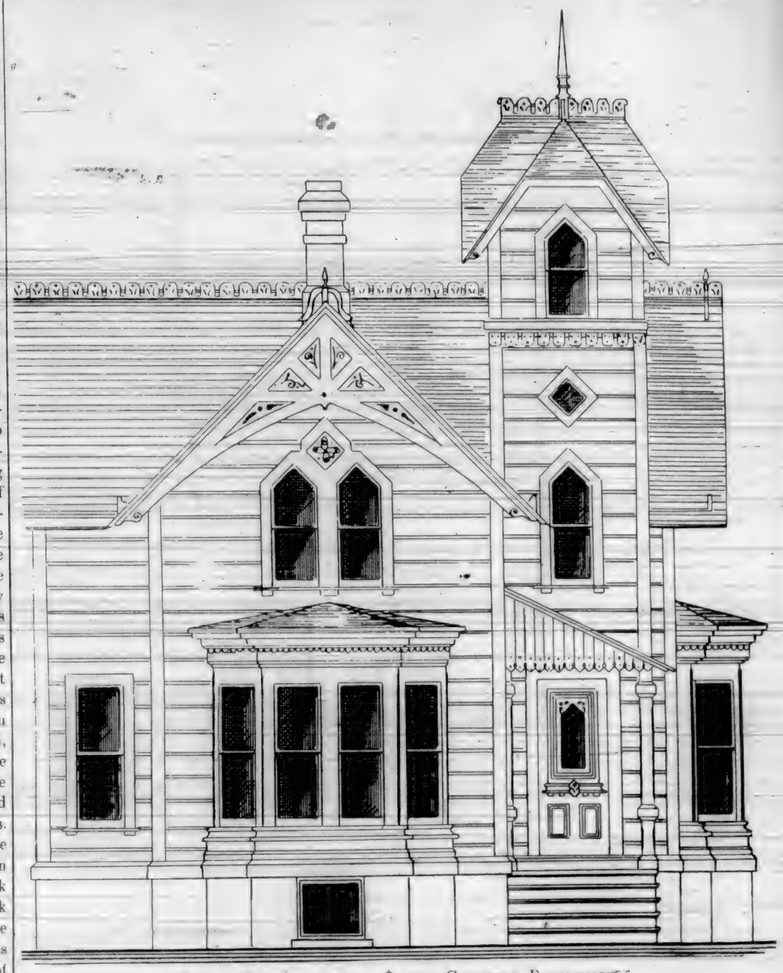
When the pulp has been reduced in the digesters and drawn off into the pulp cars, as before stated, the liquor is drained off, and clear water allowed to perculate all through the mass, thoroughly washing out all traces of soda. This liquor that drains off is the original caustic soda mixed with coloring matters and other elements in small proportions, boiled out of the wood. The after washings are also impregnated with the same elements, but weaker. All this matter is pumped into the evaporating rooms, in which are four furnaces, fitted up with a large evaporating pan, so adjusted that the flames pass near them on their way to the chimney. The hot gases are still further utilized before escaping by passing over another set of pans higher up. The liquor is pumped into these upper pans first, where some of the water is evaporated. It is then allowed to run into the furnace pans where the balance of the water is evaporated and the remaining vegetable fiber burned out. There is now left nothing but the black soda ashes, which is now dumped on the ground to dry.

In the alkali house are tanks, into which are put water, the black ash, and a small portion of lime and white ash. Steam is applied, and the mixture thoroughly boiled until converted into caustic soda, which is simply the hydrate of soda, or, in other words, soda held in solution by water. It is now run off into vats, and left standing twelve hours, or long enough to clarify. A residium sinks to the bottom, which consists of lime and the coloring matter of the black ash. The clear liquor is drawn off, and is ready for re-use in the digesters. The precipitate is thrown into other vats, and water run into it to absorb any remaining soda, a process now repeated many more times than previously.

The Art of Graining.

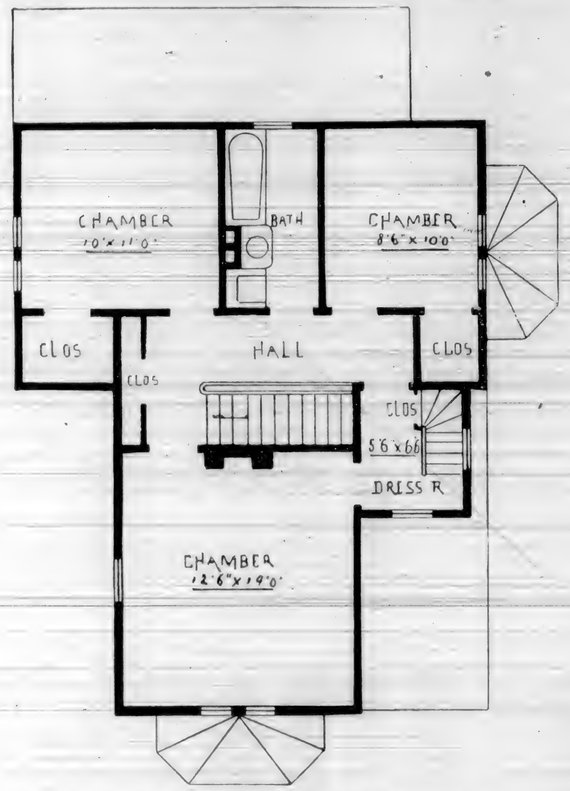
The imitation of wood is now, more than ever, a very important study, as in nature, so we find it in art, there are many diversities in effects. There is great beauty in the natural woods, when selected for any given work, but their cost being large, forbids the general use in dwelling houses. In art we have every opportunity for variations, and this can be done without very great outlay of money to procure them. The embellishment given in first-class graining to new dwellings, is far more cheerful than we find in native woods. The reason it is so, is because the woods generally selected are too strait in the grain, and do not offer much variety to please the taste. And then when old work is to be renewed, a different style of woods may be substituted for the old, and thus add new work, cheerful to the observer, for all are pleased with a change. So we find it in our private and public buildings, in all household furniture. It is not long since the latter was made of lighter shade of woods, but now we live in the *black-walnut-age*, for the taste for dark woods has become the "ne plus ultra," and nothing can please but walnut woods of every shade. On the Pacific Coast there has been a little variety thrown in by the use of laurel panels, veneers here and there of this beautiful wood, and has in a measure softened the general effect of the mournful aspect. For the coming student painters, there is an art study of the various woods and their proper imitation. There is in walnut wood many characteristics of its own, and these are the studies which must fit the student for his profession. He must note the sap growth of the wood in its sweeps and curves, along with the knots and their shades. The heart growth for specialties should be carefully studied, as their true representation is one of the best effects in the art. In oak likewise there is a great diversity of the work of delineation in the heart growth, from the nucleus or knots to the spreading wavelets, as they reach out to panel ends or the length of rails to stiles. The roots and branches claim a large share of the student's time. The former are now more generally used in panel decoration, for they offer an endless variety in design of every fantastic shape. They are whirling pools of color scattered amid rocks and foam in lights and shadow in a perfect sinuous sea of mottled masses. The branches of either walnut or oak are very pretty in form, showing curving feather-like lights, with sweeping outward, over-grain in fine lines blended in the same direction, which enriches the work on the dark back-ground of color. The oak lights form a fine study, for there is a beauty in the scattered forms, irregular in size but in marshaled ranks, forming hollow squares, platoons or files still all marching on. The stave lights, when champered on panel, offer fine effect, making light and effective graining. Then the heart growth shows the pores or checks of oak and walnut. In the oak the checks are stippled in after the heart work is done, while the pores in walnut are laid in distemper flogging, and when the oil work is done over it, the stipple shows itself plainly in the heart-growth flashes of light, where the walnut pores are so commonly seen. These are some of the studies which fit the learner to do artistic work, for he must know all the characteristics of a wood, before he is competent to undertake a job of work. Should the pupil find an opportunity to learn of a practical grainer the rudiments of the art, he will save much time and secure these aids to further perfect himself in this beautiful art. In learning the modes of others, he must not forget that nature is the *style* he must copy and aim to represent it in all its technicalities. Some grainers have a style of their own, copied partly from others with ingenious additions of their imperfect studies, which serves only to make show work. Graining, when done for the trade, is none of this class, imitation not being the rule, but rather color in marketable shape. To grain in imitation of any given wood, skill and labor of long experience are required to properly represent them. *Time-work* is more proper for the best execution of good graining, and for that reason all work of this nature should be done by the day. In order to encourage the study of the art, I propose to treat the subject in a practical way in a future article, in which the rudiments and color mixing, will be discussed.

J. E. W. C.



Front Elevation of a $3,750 Country Residence.

An improvement has been affected in wooden block flooring. The common manner of laying the block flooring often results in disappointment, because the blocks soon become loose. The improvement consists in the blocks being keyed to a cement flooring, firmly fastening them, and the cement obviates both dampness and dry rot.



SECOND STORY PLAN OF COUNTRY RESIDENCE.

Building Skyward.

A BILL introduced in the Assembly by Mr. Howe provides that no dwelling-house hereafter to be erected in this city, shall be more than 70 feet high, if the street or avenue on which it stands is not more than 60 feet wide, and that the height shall not exceed 80 feet on any street or avenue of greater width.

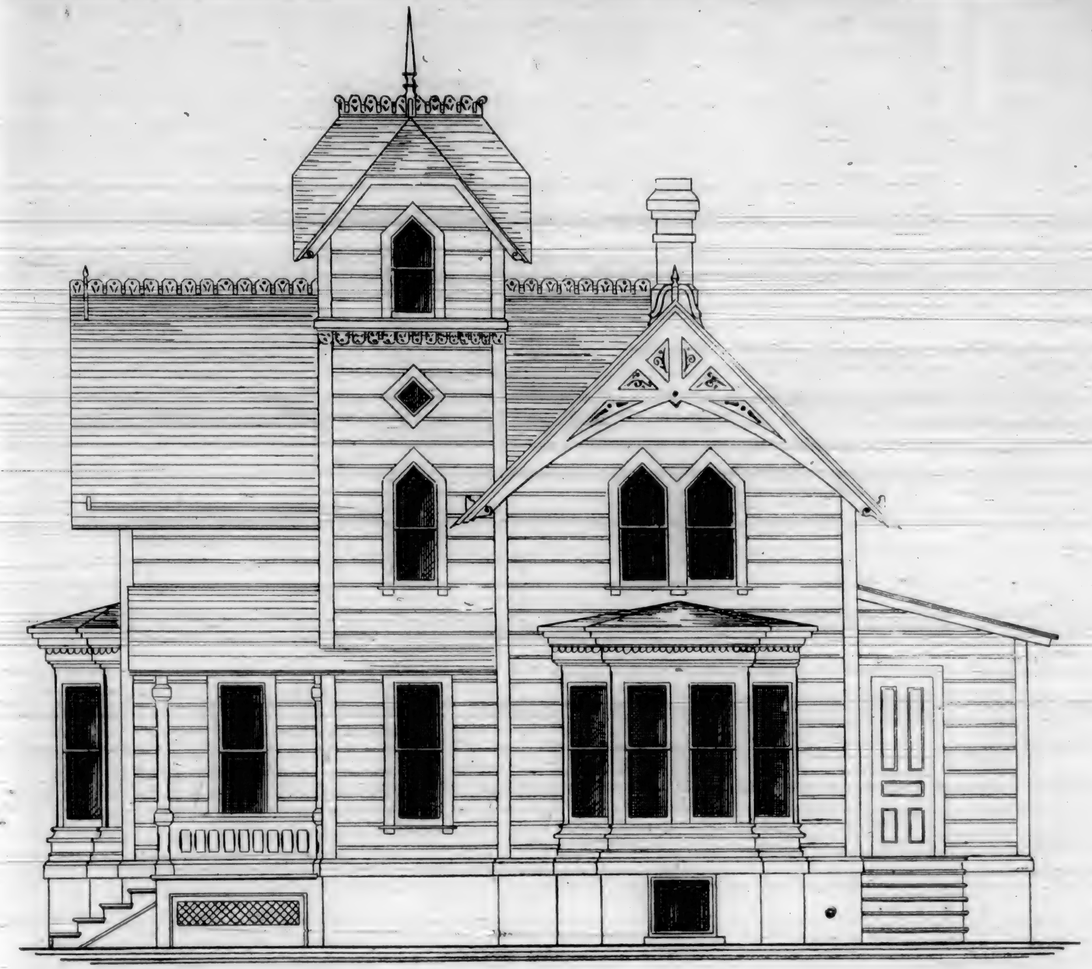
The lofty apartment houses and office buildings in which millions of dollars have been invested on this island within a few years are among the curiosities of New York. The city can grow freely in only one direction. For this reason building sites below Central Park, in the building district and along Broadway and the central avenues, have become so costly that those who own them have been led to build skyward in order to secure the greatest possible rent from every square foot of ground. They have not been restricted by laws like those which have been enacted in cities of the Old World, but the day will come when such laws will be needed here to insure the protection of life and the preservation of health. The natural limits of expansion have thus far tended to give builders more freedom than is allowed in cities that can grow outward in all directions from a center. If Berlin were growing from one end of a long and narrow island toward the other, the authorities of that city might have postponed the adoption of a regulation forbidding the erection of houses more than 79 feet high. If Paris could expand in only one direction, the height of its buildings might not be limited to 65 feet, with exceptions in certain cases. Admitting, however, that freedom in this respect is more desirable here than in those cities, it is, nevertheless, true that the time has come for the enforcement in New York of some law like that proposed by Mr. Howe. The subject is receiving attention in Chicago, where the erection of a few lofty buildings has led an association of citizens to ask for the enactment of an ordinance providing that all buildings more than 90 feet high shall be made throughout of incombustible material.

The builders of our most lofty structures—apartment houses and down-town office buildings—have in most cases been led by a consideration of their own best interests to make them fire-proof. A law that would prohibit the erection of such buildings as half a dozen that might be named, recently constructed below the City Hall, could not be defended by many arguments, nor could the erection of lofty fire-proof apartment houses, like those that now attract sight-seers near the lower end of the Park, be reasonably forbidden upon the sole ground that fire in them might endanger life and surrounding property. The buildings which we have in mind seem to be practically fire-proof, but the erection of buildings eight, ten, twelve, and even fourteen stories high that are not fire-proof should be forbidden by a rigid law. If a builder desires to increase his profits by erecting sky parlors, he should be at least, compelled to make his sky parlors safe.

On the ground of health, however, it is urged that the erection of all lofty buildings—even those that are fire-proof—should be forbidden in a crowded city. This objection may not be potent with reference to office buildings, but with reference to apartment houses it demands serious consideration. Nearly all of the great up-town flat houses now stand apart from each other. Where two or more of them are grouped the lower floors are almost sunless, and in the course of time the multiplication of these houses will convert the lower stories into gloomy caverns which the sun's rays cannot reach. They will keep the surface of the streets in almost perpetual shadow, and deprive the unfortunate occupants of adjoining small houses of sunlight, which is so powerful an agent for the preservation of health.—*New York Times.*

To Saw Rough Timber.

ALL tough timber, when the logs are being sawed into lumber of any kind, whether scantling, boards, or planks, will spring badly when a log is sawed in the usual manner, by commencing on one side and working toward the other. In order to avoid this it is only necessary to saw off a slab or plank, alternately from each side, finishing in the middle of the log. We will suppose, for example, that a log of tough timber is to be sawed into scantling, of a uniform size. Let the sawing be done by working from one side of the log toward the other, and the ends of the scantling will all be of the desired size, while at the middle some of them will measure one inch broader than at the ends. After the log has been spotted, saw off a slab from one side; then move the log over and cut a similar slab from the opposite side. Let calculations be made by measuring before the second is cut off, so that there will be just so many cuts, no more and no less, allowing for the kerf of every cut. If the log is to be cut into three-inch scantling, for example, saw a three-inch plank from each side, until there is a piece six and a quarter inches thick left at the middle. The kerf of the saw will remove about one-fourth of an inch. When a timber log is sawed in this way, the cuts will be of a uniform thickness from end to end. Now turn the log down and saw the cuts the other way in the same manner, and the scantling will not only be strait, but of a uniform size from one end to the other, if the saw be started correctly.—*Sel.*



SIDE ELEVATION OF $3,750 COUNTRY RESIDENCE

Running Locomotives.

"LOTS of chaps think it would be fun to run an engine," said the driver, as he stuck his head, a flaming torch and a long-necked oil can in under his machine, "but if the most of 'em would try it they wouldn't like it quite so well. 'Taint everybody can run a locomotive either, though I s'pose it's like running a daily newspaper, which I've heard tell everybody can do. Now, a nervous man has no business in a cab; no more has a careless one or a stupid cuss. To run an engine a man must feel his responsibility, and keep his head level. I don't believe half the people know what it is to run an engine. Now, there's the machine; that is the first thing, and it has to be in good order, and stay so. A locomotive has to stand wear and tear and weather that'd knock a stationary engine into smithereens. And no matter what emergency rises—freezing of pipes or starting of flues, a loosening of packing or heating of journals—we've got to know just what to do, and do it right quick, too. Then when we'er running there's the time-cards, and pretty often a new one. And the train orders—they are life and death and reputation to us, and to read 'em correct and to live up to 'em gives us no end of anxiety. Bet I've read a train order over a dozen times an hour—I am always so afraid of making a mistake or forgetting. You know the consequence of even a little mistake sometimes.

"Then there's signals to watch, the conductor's go'ng overhead, steam to keep up, time to make, whistle-posts and crossings to look out for, bad spots in the road to be careful on, and along with all this, there's the track ahead of ye which your eyes mustn't leave for more'n five seconds. There's the brakes, too—one is always worrying about them. I don't s'pose everybody knows, either, that we have to be mighty careful when we come to the top of a grade. You see in going up she labors hard, and so as soon as she begins to descend she makes a rush, and there's the danger of breaking your train when the rear cars are still dragging on the up grade. This danger is especially great on freights, but no good engineer fails to shut off some of his steam when his engine reaches the summit. It isn't every fool that can run a locomotive."—*Sel.*

Science of Carpentry Made Easy.

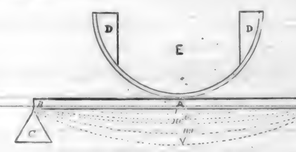
A WORK that should be in the possession of every mechanic, as its pages are full of practical, instructive matter pertaining to carpentry, bridge building, etc. Price, $5.00.

Native California Woods.

[A series of articles written expressly for this Journal, in which special attention will be given to the principal characteristics of Redwood].

THE editors of this paper have requested us to tell all that can be demonstrated regarding the woods found in the Golden State, especially as regards that which is indigenous to the Pacific Slope. In view of this they forward samples of the redwood, for physical as well as chemical investigation, both or either of which, to tell all that is demonstrable by the aid of these two sciences alone, would require a volume the size of this page and many, many leaves; but we will endeavor, commensurate with succinctness, to dwell in as brief manner as possible on the technical minutiæ, making all, or the majority, of the tests for the purpose of giving accurate information regarding the timber from the standpoint of the architect and builder.

First, its elasticity. For this test the basis is made for a stick precisely one foot square, and thirty feet between the rests, as shown in Fig. 1.



a—timber; *b b*—points 30 feet apart; *c c*—rests; *d d*—appliance to balance without weight; *E*—weights or applied pressure susceptible of being weighed; *I, II, III, IIII*, and *V*, are represented by the timber when subjected to pressure at *E*'s space; *ffff*—arcs.

With this crude drawing, we will place 1,210.239 pounds pressure, and find the stick has reached the first line, or *V*, from which it readily springs back to its original position; but if another ounce or gram weight be added, its plance is forever destroyed; hence this 1,210 pounds and a fraction represent its actual elasticity, something remarkable when we take into consideration the natural brittle texture of the wood. Now, by adding 400.7520 pounds more pressure, the timber bends down to the line marked *IIII*, and when again freed rebounds back to *V*, but would not if another atom of pressure was applied; hence its second tension strength is represented by a trifle over four hundred pounds.

We have now represented, by the two pressures, 1610.991 pounds, and the stick, permanently bent, to all intents and purposes, out of true to the extent represented by the arc in the cut. To bend down to *III*, requires 300.2711 pounds, when the timber goes back, after the weight or pressure is removed, to *IIII*; and it will be noticed with the slight addition of 300 pounds and a fraction, the timber made quite a depression, and we will call this the third tension, the best tension, really, of any timber, as will be shown from another series of tests farther on, inasmuch as the wider the space between these lower arcs and the timber, going back to the limit of previous tests, indicates less liability to break beneath first load, if left with inadequate supports.

We have now 1,911.2621 pounds pressure, the timber still whole, unfractured, as proven by its power of rebounding back to *IIII* and remaining. The fourth tension required an additional pressure of 501.3113 pounds to crowd down to *III*, when it rebounded promptly to *IIII*, showing a readiness to bear a greater load and come back to its original shape when the load was removed. We have now applied 2.412 pounds and over, and the timber's formative fabric uninjured, surified by attaining the lower limit of previous test, by the addition of 118.1112582 pounds, the timber settled to *II*, rebounding to *III*, and 16.5 pounds more brought it down to *I*, when it refused to go any better and respond or make any effort to reach its original position. Below this, so far as this test is concerned, the less said concerning it the better. Right here begin the tests to determine other strengths, which we will refer to again at another time.

It may be stated authoritatively, then, that the various tensions to which the wood has been subjected, are represented in the aggregate by 2,547.0844882 pounds, before the formative fabric has been disturbed. But the timber is not used up yet by any means; for if the bearing weight of a timber falls short when placed horizontally, it may possibly be placed at certain angles, when it will outstrip all competitors for another test. But to return to our subject. It will be noticed that the point where we applied the weights, or pressure, to determine these tensions of itself, is an arc. It is necessary to have represented the entire length of the timber, so far as bent, with a pressure applied by touching the surface of the timber precisely as represented by each arc below, illustrating the various tensions, otherwise, even if it were possible to bring hydrostatic pressure—the means we employ in laboratory practice—the results would not be accurate, inasmuch as besides an insurmountable difficulty of applying to the center of the timber, it would not press alike along the line of the depression. We wish to explain these various steps as we pass along, for there will something grow out of these that every architect and builder in the entire country should fully understand.

It has been stated that the timber referred to rebounds after further pressure. We will now examine into its structure and try to ascertain why this is so. If we count the grains in the stick, we find it to contain 158, about; these are held in place by the constituent elements of the wood itself, there being no mechanical action, whatever, where one of these circles is separated in sawing, or any division. These do act slightly mechanically, as was stated in a previous article, by their straightening out. This, too, we may have reason to refer to again.

These chemical elements of which we speak, consist of cellulose, gum, starch, gluten, and the like, but we have not submitted the wood to chemical analysis yet, neither can we, until the other tests are farther along, for apparent reasons, but will in due time. If any force is brought to bear having a tendency to displace the molecules constituting these elements, the *end* of the timber, which was previously perfectly square and smooth, will be notched and jagged precisely in proportion to the accuracy of the previous tests, and when these were completed in this case, careful counting revealed just as many of these steps on the end as could be counted grains in the timber, hence the test must be accurate, for the substance situated between each two of these grains, had been absolved or set free from the grains, hence each one of them contained just sufficient elasticity, and no more, to sustain its individual weight, and of course could not spring back.

IN Germany a very singular custom is in vogue, under which the architect himself sometimes undertakes to erect, for a lump sum, the building which he has designed. Although this is rather shocking to our notions, it can hardly be said that there is anything really objectionable in such a custom. On the contrary, under it the owner, if he has made the architect understand his wishes, can be absolutely certain of having them carried out for the price agreed upon, without extras, since the architect cannot plead that he did not understand the plans, or that something was omitted from the specifications, as an excuse for making an additional charge; and the architect himself, if he has been careless about his plans, will be taught a useful lesson by having to pay out of his own pocket the cost of making good the defects, while, if he has shown care and skill, he will be rewarded by securing the builder's profit, in addition to his own commission, without any diminution. Even in this country engineers often carry out their own designs in this way, and an architect who happens occasionally to be asked to follow their example should not, we think, be too hasty in refusing, although no one would wish to see the custom become general. One of the considerations mentioned by Mr. Cate's German correspondent against the practice of contracting with a single mechanic, is worthy of note, as suggesting a strong argument in favor of confiding the entire responsibility of buildings of the more decorative class to the architect. In replying to the question whether single or divided contracts are most in favor in Germany, this correspondent, Herr Ende, of Berlin, says that the former are not unusual "for simple and ordinary structures," but are rare in the case of elaborate and ornamental ones, unless the contractor is himself the architect; for the reason that, according to the ideas prevailing in Germany, "an artistic building can never be completely finished from the first design and the first estimate, but the chief and best portion of the work must be designed and worked out during its construction." "There is, however," he goes on to say, "an end to this when a contractor undertakes the building. Alterations can then be made only under stringent and costly conditions, which give occasion for all kinds of disputes."—*The American Architect and Building News.*

The New Odd Fellows' Hall,

[Market corner Seventh Street.]

THE business centres in all large cities are constantly changing. Especially is this fact verified in San Francisco. The building of the Occidental Hotel caused a revolution in the character of the surrounding buildings. The erection of the Harpending Block on Market Street was regarded by many as a very weak experiment, but the owner, by securing responsible firms and offering them special inducements to occupy the stores, helped to make that section of Market Street what it is to-day. The building of Dunham, Carrigan & Co's splendid hardware edifice has more particularly drawn the attention of our large importers to that section of the city, and it is but the question of a little time when the space now occupied by the foundries, etc., must give way to commercial business buildings.

Probably no one single building has caused such a change of surroundings in its neighborhood as that destined to be made by the new Odd Fellows' Hall on the corner of Market and Seventh Streets, and of which we present a fine four page engraving. We confidently predict that inside of five years this section will be within the retail business centre of the city. Property owners are earnestly considering the best means to obtain this end and are making advantageous offers to business men for the purpose of inducing them to locate in the quarter referred to, good buildings and low rents for a few years being the particular inducements.

The new I. O. O. F. Building is located at the southwest corner of Seventh and Market Streets. The lot occupies a space of 150 ft. on Market Street by 140 ft. on Seventh, with an ell section of 25x75 running through to Stevenson Street. It was the intention of those having charge of the improvements to buy, if possible, the lot at the northwest corner of Stevenson and Seventh Streets and have the new hall cover that entire section of the block; but the rapacious greed of the owner of the lot referred to prevented any such arrangement being made. The total area covered by the new building is 22,875 feet.

In the early part of April, contracts were awarded for all the different portions of the work, it being deemed best to let each distinctive part separately, instead of lumping them all together. The principal contractors are as follows: *Brick work*, J. G. Liebert; *carpenter work*, Ed. Farrell; *cast iron*, R. Llewellyn; *wrought iron*, Phœnix Iron Works; *roofing*, Cronan & Dunbar; *plumbing*, Geo. Milne; *plastering*, A. C. Corbett; *painting*, E. M. Gallagher; *granite*, Geo. Griffith; *cement*, Davis & Cowell. The entire work is under the immediate supervision of Messrs. Wright & Sanders, architects.

The front will be an exemplification of the style of architecture known as the Modern Gothic. This style was selected by the architects, because it enabled them to express in architectural form the purpose of the structure, Although at first glance but four stories are seen, yet practically the building will be five stories in height, exclusive of the basement.

The first story will be eighteen feet high. Owing to the grade in Market and Seventh Streets, this figure will be changed so as to conform to the grade in the two streets; the height of the story on the lower easterly end of the building will be nineteen feet, and on southerly end in Market Street sixteen feet. As shown on engraving, the first floor will be occupied by stores; an entrance way is also provided on each main street.

The second story is intended principally for offices. Those in the Market Street front are for renting purposes, the rest being used by the Grand Secretary, library, reading-room, etc. The library room will be situated in the extreme easterly end of the Seventh Street front, in size 40x80 feet.

The third and fourth floors will be devoted to the uses of the order. On the former will be four lodge rooms and one for the Rebeccah Degree Lodge. Quite a novelty will be introduced in the shape of the Encampment Room, which will be situated in the upper floor. Its size will be 40x40 feet, and in the centre thirty feet in height and will be made in the shape of a tent.

The basement will contain the dining hall, kitchens, pantries, etc. The former to be 62x107 feet in size and will accommodate about 1,500 people. Extra provisions have been made for large, well ventilated hat and cloak rooms. No bar room has been provided for, as it is one of the most excellent maxims of the great order of Odd Fellows "*to abhor vice in all its forms*," and so this, one of the most objectionable features commonly found in all places where public entertainments are held, will, in the magnificent temple under consideration, be found wholly wanting.

One of the main attractions of the building will be its magnificent public hall, to occupy the rear of the building towards the Stevenson Street front.

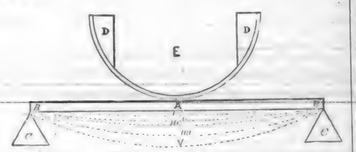
Native California Woods.

[A series of articles written expressly for this Journal, in which special attention will be given to the principal characteristics of Redwood].

THE editors of this paper have requested us to tell all that can be demonstrated regarding the woods found in the Golden State, especially as regards that which is indigenous to the Pacific Slope. In view of this they forward samples of the redwood, for physical as well as chemical investigation, both or either of which, to tell all that is demonstrable by the aid of these two sciences alone, would require a volume the size of this page and many, many leaves; but we will endeavor, commensurate with succinctness, to dwell in as brief manner as possible on the technical minutiæ, making all, or the majority, of the tests for the purpose of giving accurate information regarding the timber from the standpoint of the architect and builder.

First, its elasticity. For this test the basis is made for a stick precisely one foot square, and thirty feet between the rests, as shown in Fig. 1.



a—timber: *b b*—points 30 feet apart; *c c*—rests; *d d*—appliance to balance without weight; *E*—weights or applied pressure susceptible of being weighed; *I, II, III, IIII*, and *V*, are represented by the timber when subjected to pressure at *E*'s space; *ffff*—arcs.

With this crude drawing, we will place 1,210.239 pounds pressure, and find the stick has reached the first line, or *V*, from which it readily springs back to its original position; but if another ounce or gram weight be added, its plance is forever destroyed; hence this 1,210 pounds and a fraction represent its actual elasticity, something remarkable when we take into consideration the natural brittle texture of the wood. Now, by adding 400.7520 pounds more pressure, the timber bends down to the line marked *IIII*, and when again freed rebounds back to *V*, but would not if another atom of pressure was applied; hence its second tension strength is represented by a trifle over four hundred pounds.

We have now represented, by the two pressures, 1610 991 pounds, and the stick permanently bent, to all intents and purposes, out of true to the extent represented by the arc in the cut. To bend down to *III*, requires 300.2711 pounds, when the timber goes back, after the weight or pressure is removed, to *IIII*; and it will be noticed with the slight addition of 300 pounds and a fraction, the timber made quite a depression, and we will call this the third tension, the best tension, really, of any timber, as will be shown from another series of tests farther on, inasmuch as the wider the space between these lower arcs and the timber, going back to the limit of previous tests, indicates less liability to break beneath first load, if left with inadequate supports.

We have now 1,911.2621 pounds pressure, the timber still whole, unfractured, as proven by its power of rebounding back to *IIII* and remaining. The fourth tension required an additional pressure of 501.3113 pounds to crowd down to *III*, when it rebounded promptly to *IIII*, showing a readiness to bear a greater load and come back to its original shape when the load was removed. We have now applied 2.412 pounds and over, and the timber's formative fabric uninjured, surified by attaining the lower limit of previous test, by the addition of 118.1112582, pounds, the timber settled to *II*, rebounding to *III*, and 16.5 pounds more brought it down to *I*, when it refused to go any better and respond or make any effort to reach its original position. Below this, so far as this test is concerned, the less said concerning it the better. Right here begin the tests to determine other strengths, which we will refer to again at another time.

It may be stated authoritatively, then, that the various tensions to which the wood has been subjected, are represented in the aggregate by 2,547.0844882 pounds, before the formative fabric has been disturbed. But the timber is not used up yet by any means; for if the bearing weight of a timber falls short when placed horizontally, it may possibly be placed at certain angles, when it will outstrip all competitors for another test. But to return to our subject. It will be noticed that the point where we applied the weights, or pressure, to determine these tensions of itself, is an arc. It is necessary to have represented the entire length of the timber, so far as bent, with a pressure applied by touching the surface of the timber precisely as represented by each arc below, illustrating the various tensions, otherwise, even if it were possible to bring hydrostatic pressure—the means we employ in laboratory practice—the results would not be accurate, inasmuch as besides an insurmountable difficulty of applying to the center of the timber, it would not press alike along the line of the depression. We wish to explain these various steps as we pass along, for there will something grow out of these that every architect and builder in the entire country should fully understand.

It has been stated that the timber referred to rebounds after further pressure. We will now examine into its structure and try to ascertain why this is so. If we count the grains in the stick, we find it to contain 158, about; these are held in place by the constituent elements of the wood itself, there being no mechanical action, whatever, where one of these circles is separated in sawing, or any division. These do act slightly mechanically, as was stated in a previous article, by their straightening out. This, too, we may have reason to refer to again.

These chemical elements of which we speak, consist of cellulose, gum, starch, gluten, and the like, but we have not submitted the wood to chemical analysis yet, neither can we, until the other tests are farther along, for apparent reasons, but will in due time. If any force is brought to bear having a tendency to displace the molecules constituting these elements, the *end* of the timber, which was previously perfectly square and smooth, will be notched and jagged precisely in proportion to the accuracy of the previous tests, and when these were completed in this case, careful counting revealed just as many of these steps on the end as could be counted grains in the timber, hence the test must be accurate, for the substance situated between each two of these grains, had been absolved or set free from the grains, hence each one of them contained just sufficient elasticity, and no more, to sustain its individual weight, and of course could not spring back.

IN Germany a very singular custom is in vogue, under which the architect himself sometimes undertakes to erect, for a lump sum, the building which he has designed. Although this is rather shocking to our notions, it can hardly be said that there is anything really objectionable in such a custom. On the contrary, under it the owner, if he has made the architect understand his wishes, can be absolutely certain of having them carried out for the price agreed upon, without extras, since the architect cannot plead that he did not understand the plans, or that something was omitted from the specifications, as an excuse for making an additional charge; and the architect himself, if he has been careless about his plans, will be taught a useful lesson by having to pay out of his own pocket the cost of making good the defects, while, if he has shown care and skill, he will be rewarded by securing the builder's profit, in addition to his own commission, without any diminution. The New Odd Fellows' Hall,

[Market corner Seventh Street.]

THE business centres in all large cities are constantly changing. Especially is this fact verified in San Francisco. The building of the Occidental Hotel caused a revolution in the character of the surrounding buildings. The erection of the Harpending Block on Market Street was regarded by many as a very weak experiment, but the owner, by securing responsible firms and offering them special inducements to occupy the stores, helped to make that section of Market Street what it is to-day. The building of Dunham, Carrigan & Co's splendid hardware edifice has more particularly drawn the attention of our large importers to that section of the city, and it is but the question of a little time when the space now occupied by the foundries, etc., must give way to commercial business buildings.

Probably no one single building has caused such a change of surroundings in its neighborhood as that destined to be made by the new Odd Fellows' Hall on the corner of Market and Seventh Streets, and of which we present a fine four page engraving. We confidently predict that inside of five years this section will be within the retail business centre of the city. Property owners are earnestly considering the best means to obtain this end and are making advantageous offers to business men for the purpose of inducing them to locate in the quarter referred to, good buildings and low rents for a few years being the particular inducements.

The new I. O. O. F. Building is located at the southwest corner of Seventh and Market Streets. The lot occupies a space of 150 ft. on Market Street by 140 ft. on Seventh, with an ell section of 25x75 running through to Stevenson Street. It was the intention of those having charge of the improvements to buy, if possible, the lot at the northwest corner of Stevenson and Seventh Streets and have the new hall cover that entire section of the block; but the rapacious greed of the owner of the lot referred to prevented any such arrangement being made. The total area covered by the new building is 22,875 feet.

In the early part of April, contracts were awarded for all the different portions of the work, it being deemed best to let each distinctive part separately, instead of lumping them all together. The principal contractors are as follows: *Brick work*, J. G. Liebert; *carpenter work*, Ed. Farrell; *cast iron*, R. Llewellyn; *wrought iron*, Phœnix Iron Works; *roofing*, Cronan & Dunbar; *plumbing*, Geo. Milne; *plastering*, A. C. Corbett; *painting*, E. M. Gallagher; *granite*, Geo. Griffith; *cement*, Davis & Cowell. The entire work is under the immediate supervision of Messrs. Wright & Sanders, architects.

The front will be an exemplification of the style of architecture known as the Modern Gothic. This style was selected by the architects, because it enabled them to express in architectural form the purpose of the structure, Although at first glance but four stories are seen, yet practically the building will be five stories in height, exclusive of the basement.

The first story will be eighteen feet high. Owing to the grade in Market and Seventh Streets, this figure will be changed so as to conform to the grade in the two streets; the height of the story on the lower easterly end of the building will be nineteen feet, and on southerly end in Market Street sixteen feet. As shown on engraving, the first floor will be occupied by stores; an entrance way is also provided on each main street.

The second story is intended principally for offices. Those in the Market Street front are for renting purposes, the rest being used by the Grand Secretary, library, reading-room, etc. The library room will be situated in the extreme easterly end of the Seventh Street front, in size 40x80 feet.

The third and fourth floors will be devoted to the uses of the order. On the former will be four lodge rooms and one for the Rebeccah Degree Lodge. Quite a novelty will be introduced in the shape of the Encampment Room, which will be situated in the upper floor. Its size will be 40x40 feet, and in the centre thirty feet in height and will be made in the shape of a tent.

The basement will contain the dining hall, kitchens, pantries, etc. The former to be 62x107 feet in size and will accommodate about 1,500 people. Extra provisions have been made for large, well ventilated hat and cloak rooms. No bar room has been provided for, as it is one of the most excellent maxims of the great order of Odd Fellows "*to abhor vice in all its forms*," and so this, one of the most objectionable features commonly found in all places where public entertainments are held, will, in the magnificent temple under consideration, be found wholly wanting.

One of the main attractions of the building will be its magnificent public hall, to occupy the rear of the building towards the Stevenson Street front. The main floor will be 84x63 feet, stage 34x48 feet, four and one half feet from floor; height of ceiling 42 feet. In addition to the Market and Seventh Street entrances there will be rear exits on Stevenson Street, so in case of a fire or panic the hall can be emptied in a very short space of time.

The largest lodge room, 40x60 feet, will be situated over the Seventh Street entrance. The other lodge rooms vary in size, the smallest however being 32½x52 feet.

On account of the unusual character of the soil, more than ordinary attention is paid to the foundations. The best hard brick and Portland cement are used. The footings are eight feet wide, and up to the first floor the walls will be three feet thick. The first and second story walls will be two feet, and the third and fourth stories twenty one inches in thickness.

As shown, the first story front will be iron; above that pressed brick with stone trimmings. The roof will be of slate.

Steel girders will be used throughout the building, wherever it is necessary to use the same. They cost about the same as iron, excelling the latter however in strength, besides being more easily handled on account of the weight being considerably less than iron girders of equal strength.

The tower shown rises to a height of 165 feet from the sidewalk. The main cornice being eighty feet from same place.

It is the intention to have the building as near fire-proof as possible. The elevator shaft will be constructed of brick and be surrounded by a stone stairway extending to the roof.

The cost of the building when finished will be in the neighborhood of $300,000.

Every mechanic, property owner, material man, etc., should subscribe for the California Architect and Building News. Terms, $2.00 per annum.

Owing to the great increase in our circulation, causing great demand for advertising space, we have to announce an increase in the rates established January 1, 1884. We are continually receiving letters from parties, in regard to advantages secured by an advertisement in this Journal. Our rates are now $50.00 per page for single insertion. Proportional rates accordingly.

THE NEW ODD FELLOWS HALL OF SAN FRANCISCO. Wright & Sanders, Architects.

MDCCCLXXIV.

Interior Decoration of Business Structures.

A. C. BOND.

THE decoration of business structures necessarily posseses in many points its own special characteristics. Where carried out on an imposing scale, as in the principal apartments of banks, insurance, and commercial corporations and exchanges, it is rendered characteristically distinct from that of private residences by the more pronounced and more varied interior, constructive, and ornamental features of the building itself, multiplying forms and contributing lights and shades in carved and moulded work that allows of the most varied effects in color. Pillars and pilasters, paneled ceilings, even iron girders and brick arches—these latter presenting the combination of straight and curvilinear forms, projecting galleries, recessed apertures and stairways, loftiness and extent of area, contribute important aid to decorative effects. Richness of decoration in these offices is recognized as consistent with the commercial wealth and importance of the companies, and as indeed only doing justice to buildings, the façades, vestibules, and corridors of which command adornment corresponding to their palatial appearance within. There are private offices that, under favoring architectural conditions, but on a far lesser scale, may be said to vie with these, especially in instances where the firms are also owners of the buildings, and so have not only the pick of offices, but are assured of permanency. The constant change of tenancies, the fact that the commercial mind is not exacting as respects features of decoration, has restricted the freedom given to architects of professional decorators in this line. Yet the effect of growing taste is resulting in the introduction of more ornamental features in offices than have hitherto prevailed; light, soft tints are taking the place of glaring whiteness in walls and ceilings; wood panelings, almost essential as an accessory to decoration, is carried out through whole suites of offices; friezes and ceiling borders in oil colors, distemper, or fresco, contribute their aid, and marquetry on a moderate scale, is being carried out.

Tenants, position, and means more than ever, especially in the new and gigantic class of business buildings that have arisen, countenance well designed architectural woodwork, in which screens make such a conspicuous figure. The taste for the elegantly furnished private mansion extends to the office which it is felt should be in keeping with commanding and frequently highly decorated approaches. The decoration of offices is encouraged by the opportunities offered for distinctive individual taste, and may be said to possess a certain commercial value. That architects are seeking closer relations with decorators is an encouraging sign. It is interesting to note how closely convenience allies itself to decorative art in the internal planning of office fixtures. The offices of the new building of Mutual Life impress one with the richness of the mouldings that form the deep frieze and also the surface of the beams that divide the ceiling. Between the spandrels of the arches appear emblematic figures, always welcome in decoration where appropriate. The saffron-colored pillars, of gigantic size, ranged longitudinally along the center of the room and crowned with gilded Corinthian columns, these flanked by pilasters of similar design and material constitute imposing objects. The pillars and pilasters, together with the pillars dividing the corridor from the rooms beyond in conjunction with the mahogany balustrades of the gallery, surmounted by a handsome brass rail, afford, together with the mahogany furnishing, fine contrasting effects in color with the white mouldings, which are susceptible of much greater effect were they tinted. In comparing this interior with the equally ambitious one of the Equitable, we note the advantage of abundance of light in the former. The offices of a well-known commercial firm in Broad Street may be referred to for their rich and judicious ornamentation. Nothing can be finer in its way than the constructive appearance of a cedar wood screen, paneled in its upper portion with ground glass, each panel having a fire gilt brass gate. It is finished with a high cornice of brass, the post panels at each extremity having figures in the same metal. The several departments are enclosed on three sides with open woven screens of brass, offering a most lightsome appearance, practically avoiding the "cutting up" so often destructive of the scenic effect of well decorated offices. The office of Henry Clews & Co., in Broad Street, may be cited for its display of carefully elaborated ornamental details. The constructive forms and carvings of the counters and screens are in renaissance style, executed in San Domingo mahogany and cherry, the screens having a capping of finely designed brass work, the supports ornamented with mediæval figures. The principal portions of the screens are in small panels. For brilliancy in the display of color in wall and ceiling, brightened by contrast with lofty paneling of the wall to half its height in walnut, the main office in the Williamsburgh City Insurance Building is conspicuous. The antæ or small pilasters above the paneled dado are enriched with gilt and color in harmony with the moulded work. The darkness of the paneling beneath justifies the glow, in diversified tints, of the upper surface to prevent a gloom settling on the interior. The ground of the bronzed mouldings, as well as the surface of the ceiling, is of light olive. Even the front of the walnut counter consisting of two tiers of boldly carved walnut wood, deeply recessed, has central tiles to each upper compartment in blue figured designs on a white ground, and again by the tessellated floor.

It is well known that architects, as a body, do not favor strongly pronounced colors for wall decoration but incline to mild neutral tints, and even to fading hues in stencilled designs; for all this there are numerous decided successes in bringing brilliant but soft tones of cheery aspect, into accord with architectural woodwork. It is to be remembered that a room is viewed under very different conditions from an oil painting. No atmospheric effects have to be compassed. Wall and ceiling continually catch the eye, and they should be rendered at least attractive. An important aid to the use of bright positive colors is found in the use of gold, often, indeed, brought in as an afterthought. It has the virtue of rendering certain hues more retiring, and by attracting attention through reflection of the light which other surfaces absorb, allows of the introduction of stronger tints than would otherwise be permissible.

In some conspicuous instances the vestibule is made an important accessory to the decoration of the interior. In that of the Mills Building, a central stairway, with huge metal lic lamp stands upheld by griffins, leads to an intermediate landing, along the front of which the balustrade is continued; pillars and arches further partitioning the space, and beyond a bright effect is produced by an iron curvilinear roof with a sparkling galaxy of small beveled glass insertions. With the surrounding paneling in rich hardwood and mural enrichments, the *coup d'œil* is admirable. The entrance to the inner court, on each side of the doorway, is separated by arches and pillars. Dados of variegated marbles, polished slate of cloudy hue, are being very freely used for bases of wainscoting or as dados for vestibules and passage ways. The basement vestibule of the United Bank Building has not only its walls of marble, but the same material coats the iron girders, the only contrast to its pure hue being the buff bricks of the fireproof arches.

The opportunity for scenic display in the open court of large business structures has been turned to excellent account by architects and decorators The upward view presents successive tiers of galleries, the front tops of the landings formed into enriched cornices, the light ironwork of the balustrade portions in colors and often picked out with gold, the rails of polished mahogany, the variegated marble bases to paneled woodwork, or the polished surfaces of dados in rich woods of the walls facing on the galleries, the soft, subdued tints of their upper surfaces, the trimmings and mouldings of office doors with panels of embossed ground glass, the iron and glass roof, with curvilinear sides, the glass in colors or inserted in small, round, or angular cut forms, having as a counterpart the decorated tile flooring, of the landings, and the area beneath presents a *coup d'œil* that conveys impressions not hitherto realized in interior architecture, to which the apparent aerial lightness of the whole largely contributes.

Stained glass, so ornamental when judiciously disposed, finds its use within rather than in the outside windows of business structures, particularly in the small apertures of screens. Reference has already been made to its employment in the roofing of open courts. A most striking application of stained glass to ceilings is in the "call room" of the Produce Exchange. The light falling on this ceiling of leaded panels of glass, is softened and diffused by having first to pass through a pitched roof of thick rolled glass.

The increased extent to which metal is applied to interior decorative purposes is very noticeable, particularly iron and brass. Pillars are no longer of plain, rounded, or square shafts; used in balustrades, it is made a prominent ornamentation. Brass is coming into more general use for guard rails and cappings as well as in builder's hardware, its brightness affording good contrasts; also for standards and suspended chandeliers of light design, and in antique style befitting the forms of decoration proper to the renaissance order.

WOODS FOR OFFICE DECORATION.

The number of hardwoods available for architectural woodwork is a decided advantage for the artistic designer. Honduras mahogany and cherry take the lead. Our own native oak, stained to resemble mahogany, is largely used, and white ash stained has come into request for offices. The woods in general use for best finish are cherry, mahogany, maple, oak, rosewood, satinwood, sandalwood, chestnut, cedar, ash, walnut, ebony, white mahogany, and oak. Some of our decorators use largely white oak stained to imitate Honduras mahogany. Cherry has got into high favor of late years, recommended not only by its grain and color but the large surfaces that can be obtained. Some choice foreign woods are imported to be used for inlaying, as, amaranth, amzboyna, and telira wood. For ebonizing, the woods most in request are: pear, holly, beech, chestnut, sycamore, and plane. For enlaying, the woods used are: box, palm, bird's-eye maple, sandal and satinwood, beech and holly.

About Bricks.

AN average day's work for a bricklayer is 1,500 bricks on outside and inside walls; on facings and angles, and finishing around wood or stone work, not more than half of this number can be laid. To find the number of bricks in a wall, first determine the number of square feet of surface, and then multiply by 7 for a 4-inch wall, by 14 for an 8-inch wall, by 21 for a 12-inch wall, and by 28 for a 16-inch wall. For staining bricks red, melt one ounce of glue in one gallon of water; add a piece of alum the size of an egg, then one-half pound of Venetian red and one pound of Spanish brown. Try the color on the bricks before using, and change to light or dark with the red or brown, using a yellow mineral for buff. For coloring black, heat asphaltum to a fluid state, and moderately heat true surface bricks and dip them. Or, make a hot mixture of linseed oil and asphalt, heat the bricks and dip them. Tar and asphalt are also used for the same purpose. It is important that the bricks be sufficiently hot, and be held in the mixture to absorb the color to the depth of one-sixteenth of an inch.

Why Can't any Man Put up a Stove?

IN your last issue my attention was called to an article in which the above question was asked. Is it possible that there are men who will admit that they cannot put up a stove as good as any one? Now, this is certainly strange. Why, it is one of the easiest things in the world, save that of running a newspaper. Anybody can do it.

The only objection to the business is, that it is inclined to produce profanity. I actually have seen ministers tackle a stove for the sole purpose of giving vent to their wrath, simply because a mule had kicked them, or that contributions were light the day before. And in order to make a protracted effort they commence by undertaking to insert a 6-inch joint of pipe into the small end of a 5-inch joint.

My opinion is that every man who intends to live a pious life should employ a tinner to put up his stove. Not but what he could do it just as well himself, but his future prospects would be brighter, and he would stand a much better chance of entering the realms above, where all is peace and happiness (the future home of the tinner and plumber, and other saints of less note).

It is an undisputed fact that ninety-nine fools out of a hundred, who have not mechanical ingenuity enough to lift a latch on a gate, think they can set up a stove. And because two large ends, or two small ends of the pipe will not go together, they abuse the tinner who made it, or the fraternity in general.

I have been at the business a long time, and have worked in a number of the States, from east to west, and never had any great trouble in fitting pipe. I think the size is very uniform, under the circumstances, as a great variety of weights of iron is used, and even the same number of iron varies in thickness. If all weights are cut over the same pattern, the heavy iron will undoubtedly make the pipe a little larger, and *vice versa*. Where a crimping machine is used in ordinary pipe, one-eighth of an inch smaller at the small end, is plenty, while one-fourth inch is necessary where pipe is drawn in with mallet.

Again, where pipe is seamed, it is impossible to have every joint just the same, although the joints do not vary enough to bother a tinner in putting them together. If the people of this country would have mechanics do their work in proper shape, they would be much better off, at least, in the opinion of

JOSHKINS THE TINKER.

—*Tinner and House Furnisher.*

THE Boston *Watchman* says that within the last nine years nearly 800 churches have been burned in America, mostly through defective heating apparatus.

Every property owner should subscribe for the "CALIFORNIA ARCHITECT AND BUILDING NEWS." It is the only Journal on the Pacific Coast published strictly to advance your interests. Only $2.00 per annum.

Hanging Doors.

WHERE no architect's services are rendered in connection with a building, the doors are generally hung according to the sweet will of the carpenter, but there are two ways to hang a door, one, so as to expose the room, and another so as to screen its contents and those who may happen to be there when the door is open. The first way may be very good for public rooms, but, in regard to bed rooms, the doors must swing so that, when partly open, they will shield the apartment from view. Architects themselves are often bothered in this connection with the views of the owners. Closet doors should be hung so that the closet may receive light from the nearest windows. Doors are sometimes made to swing out on stair landings or halls, and who has not seen two doors so placed that they strike each other when opened. It is hardly necessary to add that these methods should not be adopted.

Every mechanic should at once send us $2.00 for one year's subscription to this Journal. We are earnestly laboring for your welfare, and advancement in the art of building correctly. Not only do we present in each issue all the latest developments in the science of carpentry as practiced on this coast, but we also give you the cullings of the principal Eastern journals. Back numbers supplied. Bound volumes $2.50 each.

Overwork.

A LARGE amount of sentimental rot gets into print about men killing themselves by overwork. In nine out of ten cases of this kind, the true cause of death will be found to be something besides overwork. We all know professional and business men who work harder than they ought, and yet by taking good care of themselves in the way of diet, exercise, etc., manage to enjoy good health and wear a cheerful, hearty look. Those who die from "overwork" generally use liquors and tobacco without moderation, keep late hours, and indulge in hazardous speculations outside of their legitimate business. Late hours, liquor and tobacco engender weak nerves and upset the functions of the body, while anxiety over speculative schemes acts upon the brain. With these evil agencies working against a man, some slight exposure brings on an attack of illness, and the whole body being weakened, gives way in a very short time. The sudden illness and speedy demise baffle medical skill, the stricken family and shocked friends are told that overwork was the cause of death, and the press deplores the tendency of our civilization to kill people by overwork, when the real cause of nine-tenths of these deaths is as outlined above.—*The Manufacturer and Builder.*

To remove iron taste from new kettles, boil a handful of hay in them, and repeat the process if necessary. Hay water is a great sweetener of tin, wooden and iron ware. In Irish dairies everything used for milk is scalded with hay water.

Extra Inducements to Subscribers.

Mechanic's Geometry, or the Science of Framing by the Aid of Card-board Models. With the aid of card-board models, and the rules and explanations given, the mechanic can readily learn the method of getting the length and bevels of every description of rafters, hoppers, etc. Stair work is also treated in a manner that at once arrests the attention of the student, and becomes an attractive study. This book will also be found useful, though possibly in a less degree, to those who have already become mechanics, but who have not learned the science involved in their trade. The main object of this work is the elevation of the working man to the dignity of the master mechanic. Price, $5.00.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT for $6.00.

The Artisan. Among the practical ideas in this work will be found the utility of the right angle, and its application in solving many useful problems. By means of a right angle the exact circumference of a circle is determined, once. It also shows a simple and correct method for the measurement of boards, floors, and other surfaces. It is applied to lines of any length, and divides them into equal parts. It gives the cuts and lengths of rafters, braces, and other timbers in framing. There can be no doubt as to the value of a right angle and its utility in this connection. It is clearly illustrated in the *framing square*, a tool which solves nearly every problem in practical geometry. Price, $5.00.

Book and one year's subscription for $6.00.

American Cottage Homes. This work has had an unprecedented sale in the United States since the reduction in price. The book is a large one, and contains many illustrations in the prominent later styles of architecture. Prices are given for which each design can be built. In California, however, the price in nearly every instance would have to be almost doubled to correspond to cost of work in this State. Being sole agents on this coast for the above work, we are prepared to make liberal terms to agents. Price, $3.00.

Book and one year's subscription for $4.25.

Complete and Comprehensive Details. This is the first work of its kind ever published in this country. The author justly remarks: "Ideas are as necessary as tools. Tools have no edge without them." These details furnish the mechanic with nearly eleven hundred ideas, and practical ideas that can want every day. Forty plates, 20x26 inches in size, are given for the small amount of $2.00. AGENTS CAN MAKE $5.00 PER DAY STEADY, HANDLING THIS WORK. Being sole agents on this coast, we are prepared to make liberal terms to canvassers.

Book and one year's subscription for $3.25.

Foundations and Foundation Walls. For all classes of buildings, pile driving, building stones, and brick, pier and wall construction, mortars, limes, cements, etc. Practical explanations of the various methods of building foundation walls for all classes of buildings, use of piles in building, etc. Price, $2.00.

Book and one year's subscription $3.50.

Lakey's Village and Country Homes. This is a large work, and just suited to those parties in the country who live too far away from an architect to secure his services. Designs are given for all prices of village and country homes. Several pages of details are also introduced. Price, $5.00.

Book and one year's subscription $6.00.

Builder's Guide and Estimator's Price Book. This work is chiefly intended to assist the Builder and Contractor in making estimates of the cost of work they may be competing for. It is written by the author of the "Steel Square and its Uses," which fact is a guarantee that the book is practical in its character. Price, $2.00.

Book and one year's subscription for $3.50.

Steel Square and Its Uses. Enlarged Edition. This work is just from the press, and those wanting copies should at once order them. It is a great improvement on the author's former work, containing much that is new to mechanics—some of the problems presented never having before appeared in print.

We are agents on this coast for this celebrated work, and will mail a copy to any address upon receipt of $1.00.

Book and one year's subscription for $2.50.

Moor 's Universal Assistant and Complete Mechanic. This book contains 1,016 pages. There is hardly a mechanical subject that does not receive the attention of the author. Receipts are given for *shop secrets* in every branch of the trade. Well worth the price, $2.50.

Book and one year's subscription $3.75.

Gould's Carpentry Combined with Steel Square Problems. The author being a practical mechanic, has endeavored to make his ideas so plain that any one by reading, with a little study, can thoroughly master all the problems incident to the use of the Steel Square. Price, $2.50.

Book and one year's subscription $3.50.

Village Builder. The editions of this work are almost exhausted, and copies are scarce. Price $10.00.

Book and one year's subscription $11.00.

Science of Carpentry Made Easy. The work, *par excellence*, for every mechanic to have in his possession. It is thoroughly practical in its character, and contains much information not to be found in any other publication. It excels in its methods of obtaining the length and bevels of every description of rafters, both common, hip, and valley. Price, $5.00.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT for $6.00.

Plaster, How to Make and How to Use It. It contains accurate descriptions of all tools and materials used in plastering; description and action of every variety of lime and cement; instructions for making all kinds of mortar, and doing all kinds of plain and ornamental plastering; many important recipes given. Price, $1.00.

Book and one year's subscription $2.60.

Workshop Companion. A collection of reliable recipes, rules, processes, methods, practical hints for the workshop. 164 pages reading matter to all. Price, 35 cents.

Book and one year's subscription $2.1

Practical Lessons in Architectur There is not a draughtsman in this country who would not be benefited by the possession of this work. The name implies, it is strictly a PRACTICAL WORK.

Book and one year's subscription $3.7

Interiors and Interior Details. and as its name implies, contains detail of interior finish. The plates are all h graphed. Price, $7.50.

Book and year's subscription $8.75.

Hand Saws and the Art of Saw book gives full information for putting i of saws, from a carpenter's panel saw mill. Illustrated profusely. Price, $1.0

Book and one year's subscription $2.6

Lumberman's Hand-Book. Every chanic, lumber dealer, etc., should have pocket. Upward of 250 pages, filled wit tical and useful information. Price, $2.0

Book and one year's subscription $3.2

Modern House Painting. A new design, presenting numerous elevation colors precisely as they will appear when $5.00.

Book and one year's subscription $6.0

Modern Perspective. A perfectly ne be studied by those who seek to excel for the architect as well as the draug $6.00.

Book and one year's subscription $7.5

Monckton's Practical Geometry new work, comprising problems of pri the workmen. Price, $1.00.

Book and one year's subscription $2.5

Carpenter's Pocket-Book. The pr has been reduced to 50 cents.

Book and one year's subscription $2.2

Modern Architectural Designs The plan of this work is very comprehen acter. Numerous designs are given illus lake, Elizabethan, and Queen Anne style Complete plans of each, together with hensive details, are produced in a manner the tastes of any architect or property $10.00.

Book and one year's subscription for

Detail Cottage and Constructive ure. To the general country mechan invaluable. Every part of a building detailed including store fixtures, counters, fences, etc. Price, $10.00.

Book and one year's subscription $11.00.

Artistic Homes. A. W. Fuller, a well-known architect, has given to the general public, for a small price, a very neat work containing 44 plates in the Queen Anne style of architecture. Price, $8.50.

Book and one year's subscription $4.75.

Rural Church Architecture. Mechanics and others, in the country, will find in this work a great many plans for churches of moderate cost. Price, $4.00.

Book and one year's subscription $5.25.

Practical Perspective. With thirty-six Double-page Illustrations. Cloth $1.50.

American House Carpenter. This work, by Hatfield, is justly regarded as the standard work on carpentry. Price, $5.00.

Book and one year's subscription $6.25.

Wooden and Brick Buildings. Two volumes, forming a larger collection of designs for buildings than any work yet issued. Price for the two $18.00.

Two volumes and one year's subscription $18.50.

Practical Carpentry. As its name indicates, this work presents practical answers to those questions that so frequently vex the mechanic. Price, $1.00.

Book and one year's subscription $2.60.

Street, Store, and Bank Fronts. This book is complete upon the subject of which it treats. Price, $3.50.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT $4.75.

Architect's and Builder's Companion. A new edition, by Vodges. Every mechanic should have one in his pocket. Price, $2.50.

Book and one year's subscription $3.50.

Model Homes. A work containing a great many designs in the prevalent New England styles. Price, $1.00.

Book and one year's subscription $2.50.

Building Superintendence. A new work and one that should be in the hands of every architect, contractor and student. Price, $3.00.

Book and one year's subscription $3.50.

American Stair Builder's Guide. With the aid of the rules and illustrations given, the young mechanic can, in a very short time, be enabled to lay out any and all kinds of stair work. Price, $3.00.

Book and one year's subscription $4.50.

Systematic Drawing and Shading. By CHARLES RYAN. Giving Practical Lessons on Drawing. Cloth, $1.25.

stumps, and all uncleanness. This back yard iniquity is an evil under the sun as old, at least, as the Valley of Hinnon, behind Jerusalem. Perhaps the architects and builders began it by treating the rear of the house as if it had no rights that white folks were bound to respect; and assuming that since it is to be seen by no one but the owner and his family, it may be as bald, bare, uninteresting and poverty stricken in appearance as possible. Indeed, the more bald, disjointed and penurious the back side, the more gorgeous and extravagant may be the front. We find, now and then, an isolated dwelling occupying such a position that the need of a pleasant appear-

[illegible] bottle, indigo and saffron, is not unsightly among green trees and above green turf. What then,—a treeless, turfless corner, crouching behind a high board fence, where empty barrels and boxes, old hen coops, coal sifters, last year's bean poles, broken wheelbarrows, worn-out perambulators, can be stored? These things are only valuable for kindling wood, and belong in the basement, the fuel room or the barn. Is it a place to empty the wash tub, and throw the tea and coffee grounds? The sewer is the place for that. If the street has no sewer or drain, the people who control it are heathen, civically speaking, and those who live on it might as well live in the Feejee Islands, so far as certain essential means of grace are concerned; for any street in a city or village, crowded with residences and without sewer and aqueduct, is a barbarous street, not fit for the abode of civilized human beings. Its general influence upon society at large is towards heathenism. Streets in villages or cities may properly be called "crowded" with residences unless the lot belonging to each house is of sufficient size to contain a well and a cesspool at least 200 feet apart, and from every other well and cesspool, with enough arable land to consume all the sewage of the house and barn, and to supply the fruit and vegetables for the family, hay and grass enough for the cow and horse. With only less magnificent distances than these between neighbors, wholesome living is not possible without the aid of aqueducts and sewers, and of scavengers as patient and skillful as those employed by Nature herself. Is it a place to which the sweepings of floors may be consigned? These should be sent up into the sky by way of the kitchen stove and the kitchen chimney. Or for the crumbs that fall from rich men's tables, still more from the tables of poor men? These ask but a simple covered bucket to become not merely inoffensive, but a source of profit. The same is true of ashes that fall from grates.

There is in fact no earthly excuse for the conventional back yard. Beyond a doubt it is an expensive luxury, costing those who indulge in it more actual labor—not to mention discomfort, disorder and disease—than would be required to keep the entire circuit of the house beautiful and clean.

But their chief ugliness,—the reason why I give them so conspicuous a place in our out-of-door surroundings,—is the impossibility of escaping from them, whatever we may do, upon our own premises. Whether we like it or not we must, in sheer self-defense, be our brothers' keepers. Owing for a lodge in some vast wilderness will not answer, we must own it, and live in it, or we can have no assurance that our nearest neighbor will not build his stable, plant his onions, empty his drains and feed his chickens under our dining-room windows.

We may polish up the handle of our own front door, keep our own little patch of lawn and the narrow borders along the sidewalk across our twenty-five feet of frontage in perfect order, but if the next lot happens to be a sand bank or a mud hole waiting for a purchaser to improve it, and, in the present condition of the real estate market, likely to wait till we leave our earthly tabernacles, how miserably ineffectual are the results of our own labor. Not wholly lost—indeed, nothing good is ever lost—but enormously discounted,—marred, as a strain of music is marred by the harsh, discordant note out of time and out of tune.—*The Builder.*

How to Build, Furnish and Decorate.

SIX HUNDRED and fifty illustrations, consisting of plans for every kind of a building.

A PERFECTLY NEW WORK. PRICE, $5.00.

Book and one year's subscription for $11.00.

Detail Cottage and Constructive Architecture. To the general country mechanics, this work is invaluable. Every part of a building is thoroughly detailed including store fixtures, counters, fences, etc. Price, $10.00.

Book and one year's subscription $11.00.

Artistic Homes. A. W. Fuller, a well-known architect, has given to the general public, for a small price, a very neat work containing 44 plates in the Queen Anne style of architecture. Price, $3.50.

Book and one year's subscription $4.75.

Rural Church Architecture. Mechanics and others, in the country, will find in this work a great many plans for churches of moderate cost. Price, $4.00.

Book and one year's subscription $5.25.

Practical Perspective. With thirty-six Double-page Illustrations. Cloth $1.50.

American House Carpenter. This work, by Hatfield, is justly regarded as the standard work on carpentry. Price, $5.00.

Book and one year's subscription $6.25.

Wooden and Brick Buildings. Two volumes, forming a larger collection of designs for buildings than any work yet issued. Price for the two $18.00.

Two volumes and one year's subscription $18.50.

Practical Carpentry. As its name indicates, this work presents practical answers to those questions that so frequently vex the mechanic. Price, $1.00.

Book and one year's subscription $2.60.

Street, Store, and Bank Fronts. This book is complete upon the subject of which it treats. Price, $3.50.

One copy of the above and one year's subscription to the CALIFORNIA ARCHITECT $4.75.

Architect's and Builder's Companion. A new edition, by Yodges. Every mechanic should have one in his pocket. Price, $2.50.

Book and one year's subscription $3.50.

Model Homes. A work containing a great many designs in the prevalent New England styles. Price, $1.00.

Book and one year's subscription $2.50.

Building Superintendence. A new work and one that should be in the hands of every architect, contractor, and student. Price, $3.00.

Book and one year's subscription $4.25.

Cottage Homes. A new work containing numerous designs of styles in vogue in New York and vicinity. Price $5.00.

Book and one year's subscription $6.00.

Handrailing and Staircasing. A complete set of Lines for Handrails by "Square-cut System," and Full Practical Instructions for making and fixing Geometrical Staircases. By FRANK O. CRESWELL, of the Liverpool School of Science, Medallist for Geometry. With upwards of One Hundred Working Drawings. Cloth $1.50.

Book and one year's subscription $3.00.

Drawing for Carpenters and Joiners. With Elementary Lessons in Freehand and Object Drawing. Containing 250 Illustrations and Drawing Copies. Cloth, $1.75

Book and one year's subscription $3.25.

Drawing for Bricklayers. With the Elements of Freehand, Object and Plan Drawing. Containing Two Double and Thirty-two Single Pages of Illustrations adapted for Architectural Drawing. Cloth $1.50.

Book and one year's subscription $3.00.

Drawing for Cabinet-Makers. With Lessons in Ornamental and Object Drawing; Elementary Instruction in Water-Colored Drawing. Containing Twenty-four Single and Five Double-page Plates. Cloth $1.50.

Book and one year's subscription $3.00

Drawing for Stonemasons. With Elementary Lessons in Freehand and Object Drawing and a concise History of Masonry. Containing six Double and Twenty-five Single Pages of Illustrations. Cloth $1.50.

Gothic Stone Work. Containing the History and Principles of Church Architecture, and Illustrations of the Characteristic Features of each Period, the Arrangement of Ecclesiastical Edifices, etc. With Seven Double and Eighteen Single-page Plates. Cloth $1.50.

Building Construction, The Elements of and Architectural Drawing. With 130 Illustrations. 128 pp., Cloth $1.25.

Book and one year's subscription $3.00

Linear Drawing and Practical Geometry. With about 150 Illustrations, and six Whole-page Diagrams of Working Drawings. 128 pp., cloth, $1.25.

Linear Drawing and Projection. The Two Vols. in one. By E. A. DAVIDSON. Cloth $1.75.

Cutting Tools Worked by Hand and Machine. By R. H. SMITH, Professor of Mechanical Engineering, Sir Joseph Mason's College, Birmingham. Price $1.50.

ook and one year's subscription $3.00.

Carpenter and Joiner. This most excellent work, by Riddell, is well worth study by every one who desires to become proficient in the mechanic's trade. Price, $7.50.

Book and one year's subscription $8.50.

American Stair Builder's Guide. With the aid of the rules and illustrations given, the young mechanic can, in a very short time, be enabled to lay out any and all kinds of stair work. Price, $3.00.

Book and one year's subscription $4.50.

Systematic Drawing and Shading. By CHARLES RYAN. Giving Practical Lessons on Drawing. Cloth, $1.25.

History of Architecture	**$15 00**

Back Yards.

[From a lecture by E. C. Gardner.]

NATURE does not ask her visitors to shut their eyes and stop their ears until they stand before her front door. From whichever side we approach she is always gracious and cordial. We put on a bold front of paint, varnish, plate glass, marble steps, gilded bird cages, scarlet geraniums, peg-top evergreens standing on their heads, and rectangular patches of shaven lawn; while our back yards, supposed to be hidden from the public gaze, are full of dead men's bones, empty fruit cans, broken bottles, old board fences, sink drains, waste paper, worn-out overshoes, cabbage stumps, and all uncleanness. This back yard iniquity is an evil under the sun as old, at least, as the Valley of Hinnon, behind Jerusalem. Perhaps the architects and builders began it by treating the rear of the house as if it had no rights that white folks were bound to respect; and assuming that since it is to be seen by no one but the owner and his family, it may be as bald, bare, uninteresting and poverty stricken in appearance as possible. Indeed, the more bald, disjointed and penurious the back side, the more gorgeous and extravagant may be the front. We find, now and then, an isolated dwelling occupying such a position that the need of a pleasant appearance from all points of the compass has evidently been admitted. But, as a matter of fact, houses that are entirely surrounded by others, whatever their relative position may be, are the very ones that have no right to the abomination of desolation known as a back yard.

There is no more groundless delusion than this: that such a skeleton closet is a necessary attachment to a well-organized household. Is it a garden to walk in, in the cool of the day? This needs no concealment other than simple shrubbery, and vine-covered arbors will supply. A croquet ground? This surely is not to be hidden. A "clothes yard?" The weekly display of white linen, with occasional gleams of scarlet, indigo and saffron, is not unsightly among green trees and above green turf. What then,—a treeless, turfless corner, crouching behind a high board fence, where empty barrels and boxes, old hen coops, coal sifters, last year's bean poles, broken wheelbarrows, worn-out perambulators, can be stored? These things are only valuable for kindling wood, and belong in the basement, the fuel room or the barn. Is it a place to empty the wash tub, and throw the tea and coffee grounds? The sewer is the place for that. If the street has no sewer or drain, the people who control it are heathen, civically speaking, and those who live on it might as well live in the Feejee Islands, so far as certain essential means of grace are concerned; for any street in a city or village, crowded with residences and without sewer and aqueduct, is a barbarous street, not fit for the abode of civilized human beings. Its general influence upon society at large is towards heathenism. Streets in villages or cities may properly be called "crowded" with residences unless the lot belonging to each house is of sufficient size to contain a well and a cesspool at least 200 feet apart, and from every other well and cesspool, with enough arable land to consume all the sewage of the house and barn, and to supply the fruit and vegetables for the family, hay and grass enough for the cow and horse. With only less magnificent distances than these between neighbors, wholesome living is not possible without the aid of aqueducts and sewers, and of scavengers as patient and skillful as those employed by Nature herself. Is it a place to which the sweepings of floors may be consigned? These should be sent up into the sky by way of the kitchen stove and the kitchen chimney. Or for the crumbs that fall from rich men's tables, still more from the tables of poor men? These ask but a simple covered bucket to become not merely inoffensive, but a source of profit. The same is true of ashes that fall from grates.

There is in fact no earthly excuse for the conventional back yard. Beyond a doubt it is an expensive luxury, costing those who indulge in it more actual labor—not to mention discomfort, disorder and disease—than would be required to keep the entire circuit of the house beautiful and clean.

But their chief ugliness,—the reason why I give them so conspicuous a place in our out-of-door surroundings,—is the impossibility of escaping from them, whatever we may do, upon our own premises. Whether we like it or not we must, in sheer self-defense, be our brothers' keepers. Owing for a lodge in some vast wilderness will not answer, we must own it, and live in it, or we can have no assurance that our nearest neighbor will not build his stable, plant his onions, empty his drains and feed his chickens under our dining-room windows.

We may polish up the handle of our own front door, keep our own little patch of lawn and the narrow borders along the sidewalk across our twenty-five feet of frontage in perfect order, but if the next lot happens to be a sand bank or a mud hole waiting for a purchaser to improve it, and, in the present condition of the real estate market, likely to wait till we leave our earthly tabernacles, how miserably ineffectual are the results of our own labor. Not wholly lost—indeed, nothing good is ever lost—but enormously discounted,—marred, as a strain of music is marred by the harsh, discordant note out of time and out of tune.—*The Builder.*

How to Build, Furnish and Decorate.

SIX HUNDRED and fifty illustrations, consisting of plans for every kind of a building.

A PERFECTLY NEW WORK. PRICE, $5.00.

Hot Water Circulation.

HEAT is diffused through water in a very different manner to what it is through solid substances. When the heat is applied to the bottom of a boiler or other vessel containing water, the first effect is to expand the nearest layer of water to the fire. The first, by reason of its heat, makes this layer of water specifically lighter than the colder water which may be by the sides, and especially that above, and these layers being lighter than the cold above, it allows the colder water to descend, when the hot water naturally rises or floats upon the molecules of the colder or denser water which surrounds the hot; then the cold water from above, by reason of its extra density, immediately sinks to the bottom of the boiler, when it again becomes heated and again lighter in its turn. These succeeding fresh layers of heated water will continually carry the heat from the bottom of the boiler to the highest point of the circulating-tank, which heat, if the pipes and tanks be not too large, is finally and gradually diffused through the whole of the water within such pipes and tanks.

It would appear (from the preceding facts) plain that the colder the water the heavier it will be, while the lighter and warmer particles will rise to the surface; but even in this there is a limit, which can only go down to 40° F., and from this point down to 32° F., when the molecules of water undergo a very remarkable change. Between the above degrees there is no contraction or expansion; therefore it, bulk for bulk, does not become heavier or lighter; but we are surprised to find its bulk increase when the degree of heat is below 32° F., when it crystallizes into ice, and this expansion goes on in strict accordance to each degree of cold below the 32°; hence the reason why leaden and other pipes burst in times of frost. Of course my readers have seen ice floating on the surface of water, which will prove the above assertions in the most conclusive manner.

From the above it is plain that the circulation of hot water is brought about owing to the difference in the weight of the water at different points, caused simply by the expansion and contraction of the water itself; therefore, if the source of heat be permanent, the particles are rapidly brought into action, and the particles in a vertical tube soon become heated, and by their expansion must exert a pressure on all parts of the pipes, the branches included. Now this, together with the levity of the water in the boiler, establishes a current, when the cold water from the coils, branches, etc., commences to flow in the direction of the boiler, and thus supplying the heavy or colder water continually, which, of course, takes the place of the lighter particles, known as hot water. To find the force with which the colder water runs toward the boiler, you must know the specific gravities of the water in the flow and return pipes, the flow being the ascending and the return the descending; the difference between them will be the motive power or the effective pressure. You can arrive at this point by ascertaining the temperature of the water in the return-pipe and boiler, or flow-pipe. If the difference in heat is only a few degrees, of course the difference in the speed of circulation of the water will be accordingly; say it is only 4° or 5°, which is very small, but quite sufficient in a well-arranged system to maintain constant circulation. Let us assume that we have 8° of heat in our boiler, the return-pipe is standing at 180° and the flow to be 188°. Let the top of the flow-pipe be, say 18° above the top of return; the difference in weight will be about ⅛ ounce on the square inch, and this will be the amount of motive power obtained for the circulation, no matter what may be the length of pipes attached to the apparatus; and should there be, say 50 yards of 4-inch pipes, which will contain 80 gallons of water, with a 15-gallon boiler, you will then have 95 gallons, or 950 pounds weight, kept in continual motion by the 8° of heat, or ⅛ ounce pressure. Of course the size of pipes will make a wide difference in the motive power, which increases with the size of the pipes; thus, in a 4-inch pipe you will get four times as much as in a 2-inch, and so on; but, as the resistance increases equally with the power, the actual working effect is precisely the same in all sized pipes.

Again, the motive power can be increased by allowing the water to cool down before it gets back to the boiler, either by increasing the height of the flow and return pipes, or by doubling the difference of the temperature between flow and return; or, of course, an extra power can be obtained by doubling the difference of the temperature between the return and flow pipes, when the same increase of power is obtained as by the doubling of the vertical heights; or by trebling the vertical height of the flow and return pipes, the same effect is produced as by trebling the difference in the temperature of the water.

A difference in the motive power is also made by diminishing the diameter of the pipe in such a manner that a longer amount of surface will be exposed, and in proportion to the amount of water within, this, of course, allows more cooling surface, and consequently the return-pipes can give off more heat in a given time, thus making the return-water denser, and consequently quicker in action. Of course, when you do this you have more friction, which will be readily understood from the following:—

It is certain that the sides of the pipes greatly retard the flow of water; therefore a considerable deduction must be made, in some cases to the enormous extent of 80 per cent. In small pipes there is a greater amount of friction than in larger ones, owing to the relative amount of surfaces; besides this, small pipes cool quicker than larger ones, and thus the velocity is increased, as also is the friction, so that, supposing that we have a 4-inch pipe, the amount of friction is, say one; in a 2-inch pipe there is twice as much, and in a 1-inch four times as much as in a 4-inch; and you should also know that by increasing the velocity, so in proportion will be the friction, nearly as the square of the velocity. It should also be known that in all hot-water apparatus the speed of circulation varies according to circumstances; therefore it is difficult to calculate. One thing is certain—that the velocity in all hot water is quickest in their centers.—*Sel.*

AN architectural novelty in New York City is the duplex apartment house. Its peculiarity consists in having twice as many stories in front, so far as the arrangments of the different flats is concerned, as it has at the back. This device gives very high ceilings for the parlors and dining-rooms, and economizes space by means of low ones for the kitchen and sleeping-rooms.

Architectural Drawing, $2.00.
Drawing and Shading, $1.25.

N. D. Goodell.

SACRAMENTO'S PIONEER ARCHITECT.

MR. GOODELL was born on the eighteenth day of April, 1814, in the little town of Belchertown, Mass.; was brought up on a farm as a farmer till he was 19 years old, at which time he went to an adjoining town (Amherst) to learn the carpenter and joiner's trade with a Mr. Howland, where he served for one year, for $35.00 and board. After the expiration of his time he went to Springfield, where he worked another year for a contractor by the name of Wright, after which he went into business for himself in Belchertown, his native place, and met with fair success, erecting some of the best buildings in the place, one of which being the town hall. About this time Mr. Goodell took unto himself a wife. Soon after he was married he built for himself one of the finest residences in the town, after which he had many calls not only in town, but from the adjoining towns to erect buildings and draw plans, more particularly from Ware Village. At this time it became necessary not only to work, but to study the *art* of building; consequently he purchased a number of architectural works and drawing instruments, and by working daytime at his trade, and studying architecture and draughting every evening, he was soon enabled to make his own drawings, also those for other parties who needed them. He had a number of calls from Ware Village; in fact he had so many from that place, he finally moved there, where he built many of the best residences in the place. Before he had been there two years, the agent of the largest cotton manufacturing establishments in that part of the State came to Mr. Goodell to inquire his price by the year to be the general manager, architect and superintendent of all their buildings, which would consist of two or three new factories, and one or two hundred new houses, etc.; the bargain was soon made, and the young man remained with the company about five years. At this time the California gold fever broke out, when Mr. Goodell made up his mind to go to California. He formed a company of twelve young men and had the honor of being elected their president. They left New York on the 29th of March, 1849, in the brig *Everet* for Panama, arriving at that place on the 14th of April, where they stayed nearly a month; finally they secured passage on a small brig by the name of *Copiapo* for San Francisco, Cal., where they arrived on the 14th of August, 1849. They went ashore and landed at the foot of Jackson on Montgomery Street. At that time there was scarcely a house in San Francisco, except a few adobes. The next day the party went up the river in a little schooner to Sacramento, and they camped in that place under large trees between the river and where the railroad depot now stands (the ground at that point at that time was some twenty feet lower than at present, 1884). There was not a single wooden building in the town at that time, there being no lumber to build with; the consequence was the people set up poles or sticks and tacked any kind of cloth to them. As usual with all the first comers to this coast, Mr. Goodell had the "gold fever," and we find him for a while prospecting around Mormon Island, Hangtown and other places, without, however, meeting with much success. He finally made up his mind to return to Sacramento and work at his old trade of carpentering, arriving in Sacramento March 29, 1850. There he found business lively, buildings going up in all directions, consequently he had no difficulty in finding carpenter work to do at sixteen dollars a day. No one wanted an architect (as such) in those days; every one built cheaply as possible. Those were the flush times of California. Thus Mr. Goodell worked along from year to year in the building line and was very successful in that business; but at last an opportunity came (in 1861 or '62), when he could practice at his former profession of architecture. Mr. H. Wachhorst, desiring to erect a building and finish the interior for a jewelry store, selected Mr. Goodell as his architect. Upon the completion of the building, such was the satisfaction given by Mr. Goodell's design, that numerous orders were given to him to prepare plans for buildings, the first being James Carrolan (10 and H.) then John Carroll, Frank Ebner, Theodore Millican, General Redington, Albert Gallatin and Charles Scudder, all of which gave instructions for plans of houses, prices varying from $14,000 to $40,000; then plans were prepared for the grammar school building, Sixteenth and J Streets, which cost $60,000. Mr. Goodell was also the architect of the Sacramento County Hospital, one of the finest hospitals in the State; his plan was adopted as being the best of ten, which the supervisors had to select from. Under the direction and superintendence of Mr. Goodell, the pioneer architect of Sacramento, some two hundred of the best dwellings in the city of Sacramento, besides hundreds of smaller and cheaper ones, have been built. In the last year he has been the architect of four of the best stores and business places in the city, viz.: Waterhouse & Lester's Warehouse, J Street between Seventh and Eighth, the Grangers' hall at Tenth and K Streets, Mrs. M. E. Gregory's building on Second Street between I and J, at a cost of $20,000 each; also Green & Trainor's Warehouse on Second Street between I and J, at a cost of $12,000, besides some thirty other buildings of different kinds.

N. D. GOODELL.

Lime in Bricks.

MANY bricks become spoiled when they are made from clay which contains lime in such quantity, that, after burning, the lime becomes hydrated sooner or later, and thus renders the brick useless. This may be prevented by placing the bricks, as soon as they are removed from the oven, when they are still warm, in a hole or tank, piled on each other, and throwing water over them, so as to cover them entirely with water. A few hours afterwards, when bubbles no longer come to the surface, the bricks can be taken out of the water. By this operation the slaking of the lime, which takes place in bricks not thus treated, by the slow absorption of the humidity of the air is entirely prevented, as the lime is greatly modified by the said operation.—*Clay.*

The Upper Story.

"LET him that is on the house top not come down," and let him that is groping in the dampness and the gloom of basements, back alleys, narrow, shaded streets and courts, dismal second story fronts that look out upon the blank, brown stone walls across the way, the more dreary rear parlors that overhang the back yards of the adjoining streets, or, dreariest of all, the small rooms that cluster around the air shaft;—let him climb or be carried to the vantage ground of the roof. If he lives in a crowded city, if it is summer time, and if he is wise he will stay there as long as his engagements will permit.

The marked tendency to build skyward in our large cities is easily accounted for by the extremely high value of floor room, whether it is twenty feet under ground or one hundred feet above the surface, but the throwing away of the uppermost floor of all, and in many cases the most delightful of all, is one of the peculiar extravagances of modern civilization for which no rational excuse can be given.

The actual cost of preparing a roof that should serve its purpose as a roof perfectly, and at the same time be permanently available as a floor, would be trifling as compared to its value in places where the close crowding of buildings implies great value to horizontal space. There are a variety of uses that could be made of such an open plateau, its chief value in cold climates being, of course, in the summer, but then it would be invaluable both in the residence and in the business portions of large cities. The hanging gardens of Babylon were not a circumstance to what the roofs of New York might be made if they were treated with the skill and economy that ought to characterize a center of modern civilization. Not that it would be expedient to make them actual gardens for fruit, flowers and trees of all sizes, but they could be made very beautiful, and far more pleasant and comfortable out-of-door resorts than the small, close yards and enclosed areas upon the ground. It would not be necessary that such roofs should be made of iron and masonry. A wooden structure properly protected by asphaltum would be secure from decay even if covered by a sufficient depth of soil to sustain a substantial turf—provided that were desirable. Still further advantage and wider opportunities could be secured by the co-operation of adjacent owners. Even in the country where ground room is of little value the advantage of the upper level would almost justify the architectural deformity of a flat roof, provided it were supplied with all the modern conveniences, so guarded that the children could not fall off if they tried, and timid people need not be afraid of jumping overboard. A place where the boys could "camp out" on warm summer nights, and where a hammock swung beneath an awning would be the breeziest and coolest of lounging places. The hot, slippery, rattling, shining, tin roof and the impassable gravel commonly found on flat roofs give no intimation of the pleasant possibilities of the situation. If the "deck" of "French roofed" houses were devoted to such purposes of use and enjoyment there would be a reasonable apology for the usual ugliness. The climbing of stairs would keep the invalid and the indolent from improving these elevated privileges, but where elevators are in use there is no excuse for the desertion of the house top. —*The Builder.*

For Painters.

EXPERIENCE shows that the work in the paint shop is much better handled by working the men in teams as much as possible. It pushes the work along faster, with better results than when the workman is left to himself with his own individual piece of work.

Care must be taken in selecting men for teams, that there must be harmony with each other and a mutual desire to see the work go through right. The selection of partners should never be left to the men themselves, or put-up jobs may be the result, sooner or later. It is quite necessary that one man on each team should be a pusher; this method will bring out to full play the working force of each. If the right men are thus brought together, there will be a willingness on the part of each to draw the others' attention to any fault in the work, and work when finished will be more free from defects. The best workmen never fail to see something that if seen sooner might have been made better.—*Painters Journal.*

Sunlit Rooms.

NO ARTICLES of furniture should be put in a room that will not stand sunlight, for every room in a dwelling should have the windows so arranged that some time during the day a flood of sunlight will force itself into the apartment. The importance of admitting the light of the sun freely to all parts of our dwellings *cannot* be too highly estimated. Indeed, perfect health is nearly as much dependent on pure sunlight as it is on pure air. Sunlight should never be excluded except when so bright as to be uncomfortable to the eyes. And daily walks should be taken in bright sunshine. A sun-bath is of more importance in preserving a healthful condition of the body than is generally understood. A sun-bath costs nothing, and that is a misfortune, for people are deluded with the idea that only those things which cost money can be good or useful. But remember that pure water, fresh air, and sunlit homes kept free from dampness, will secure you from many heavy bills of doctors, and I give you health and vigor which no money can procure. It is a well-established fact that the people who live much in the sun are usually stronger and more healthy than those whose occupation deprive them of sunlight. And certainly there is nothing strange in the result, since the same law applies with equal force to nearly every animate thing in nature. It is quite easy to arrange an isolated dwelling so that every room may be filled with sunlight some time in the day, and it is possible that many town houses could be so built as to admit more light than they now receive. —*Carpentry and Building.*

New Stone Saw.

A NEW sort of saw for cutting stone is described in *La Semaine des Constructeurs*, which seems to have advantages over those commonly in use, and is easily and cheaply made and operated. In place of the ordinary long steel blades, supplied with sand to enable them to grind their way into the stone, the new machine presents only a slender endless cord, composed of three steel wires twisted together, which is stretched over pulleys in such a way as to bring the lower portion horizontally over the stone to be cut. The frame carrying the pulleys is movable, so that the cord can be brought into contact with the stone, or lifted away from it, at pleasure, and the whole is kept in rapid motion, while water falling in drops from a reservoir above serves to moisten the stone. The three wires which form the saw differ from the ordinary kind in being square in section, and by twisting into a cord they are so turned as to present a succession of oblique cutting edges, which act, when set in motion, in nearly the same way as so many small chisels, while the rapidity with which the blows follow each other probably adds to the effect.

Utilizing Ashes.

A PATENT has lately been granted for the use of ashes in making mortar. It has been found that the fine portion of domestic ashes is capable of being converted with a small proportion of lime, into a mortar having, when a month old, a tensile strength of from four to five times that of common sand and lime mortar, or about 80 pounds per square inch. Sand-mortar a month old has a tensile strength of 20 pounds. Ashes and lime, mixed as beton, gives a tensile strength of 140 pounds and a crushing strength of over 1100 pounds per square inch. It will thus be seen that, by utilizing the ashes for mortar, a large part of the expense of removal could be saved, together with the whole cost of procuring sand for the purpose, and, at the same time, a very superior article of mortar be produced. In consequence of the small quantity of lime required (10 per cent.), it would be necessary to mix the mortar by machinery at a mill and deliver it ready for use. This practice prevails to a great extent in European cities on account of the superiority of milled over hand-made mortar. Ash-mortar has the additional advantages of resisting the action of water as soon as it has set (in from two to three days), and also the combined action of fire and water, the quantity of lime being so small and the chemical union with the ash so complete that the application of heat does not produce free oxide of lime, as in the case of sand-mortar, and consequently does not swell when water is applied to the heated mortar. The ash-mortar forms when set, a silicate of lime and alumina, and hardens uniformly throughout, like cement; while sand-mortar, when set, is but an imperfect carbonate of lime, the sand furnishing the nucleus around which the carbonate forms.—*Carpenter and Builder.*

MASONS' and BUILDERS' EXCHANGE
OF SAN FRANCISCO,
Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

Kitchen Cesspools are Dangerous Nuisances.

A CESSPOOL is in old English a "sosspool"—that is, a "soakpool"—a place into which liquid slops and offscourings may be run, and from which, as usually constructed, it is hoped that the liquid portion will soak or drain away, thus sparing the proprietor the trouble of emptying it. The term is most generally applied, at present, to receptacles or cisterns constructed underground in the vicinity of the house, to receive the kitchen-slops and sink wastes, as distinguished from privy-vaults or receptacles intended only, or chiefly, for the reception of excreta, but it is also used by some writers as including the latter, and, as a matter of fact, a large number of cesspools receive both kinds of waste. The cesspools to which we especially refer at present are those into which excreta are not allowed to enter, but which are devoted chiefly, if not exclusively, to the reception of kitchen-waste. From time to time inquiries are received by *The Sanitary Engineer* which indicate that the writers suppose that the only dangers in house-drainage are connected with the disposal of excreta, with privy-vaults or water-closet wastes; and that if these are properly arranged the sink-slops need little attention. This is a mistaken opinion, and it is time that people learned to recognize it as such. No doubt it is true that water-closet waste is more dangerous to health than kitchen-slops; it is more likely to contain specific contagia, and is more offensive, but considered merely as furnishing material in which may be developed dangerous organisms, as decaying organic matter or filth, there is not so much difference between these two forms of waste products after all, nor is a cesspool less offensive than a privy-vault. Neither of them are satisfactory appendages to a house, but where their employment becomes a necessity the same precautions as to location, construction, etc., should be applied to one as to the other. The essential points are to prevent leakage by making them water-tight, to provide a free outlet for the gases which will be generated in them, and to locate this outlet at such a height that there shall be no danger that the gases escaping from it shall blow into the house. Such cesspools should be small, and emptied regularly and frequently.

The most unwise disposition which can be made of a cesspool is to connect the upper part of it with a sewer. When a street is sewered, the cesspools on that street should be cleaned out and filled up with fresh, clean earth and the house-drainage be connected directly with the sewer. To retain the cesspool under such circumstances is to insure that all the house-waste shall be in a putrefying condition before it enters the sewer, and hence make it impossible to keep the air in the sewer inoffensive—*The Sanitary Engineer.*

THE PAINTER'S FOREMAN.
A BOOK OF VALUABLE RECEIPTS.

It explains how to grain or imitate French Walnut that cannot be discounted; also Black Walnut, Oak, Ash, Chestnut Cherry, Satinwood, Bird's Eye, and Curly Maple, and the different woods that are imitated by graining. It gives you a sample color of the different kinds of background used to imitate the different kinds of wood, how to mix and what colors to use to make them, and how to apply them from the first coat to the last.

The graining department is explained so clearly and fully that by following the directions any one can do a first-class job of graining. It also explains how to do different kinds of Fresco work, what colors to use, how to mix and apply them. How to grain or imitate the different marbles, what colors to use, how to mix and apply them. How to make the different kinds of wood fillers, the different kinds of oil finish, the different kinds of polishes. How to gild letters on wood. How to make and use smalt. How to paint banners, etc. How to gild on japan, tin signs. How to make changeable signs that will read three different ways on same board. How to letter glass signs. How to do pearl work. How to gild on glass. How to color glass. How to ebonize wood. How to make paint for school blackboards, etc., etc., etc.

In fact, it is the only work published that explains fully and clearly the different secrets of the painting art.

Price, by mail, post-paid $2.00.

ADVERTISING RATES.

Front Cover, outside, each insertion, $2.50 per square.
Back Cover, outside, each insertion, $2.00 per square.
Page preceding reading matter, $1.75 per square.
Page following reading matter, $1.50 per square,
Inside Pages, each insertion, $1.00 per square.
Full Page, inside, one insertion, $40.00.
Each subsequent insertion according to agreement.

A square is seven-eighths of an inch in length by width of column.

Advertisements alone inserted that refer to materials used in the construction and furnishing of houses, and to matters and trades belonging to the building interest.

NO OTHERS RECEIVED.

Advertisements inserted for three months or less are payable in advance; payable quarterly when inserted for a longer period.

When money is sent for subscriptions, the receipt of a copy of this journal is an acknowledgment that it has been received. Unless requested we do not send receipts.

A Healthful State of Building Activities.

NOTWITHSTANDING the slight falling off in the number and value of contracts for buildings reported this month, over the preceding months of the year, they are larger in number and amount than for the corresponding months of 1883, thus showing that the tide of substantial prosperity is still on the flow in San Francisco. Our list of improvements, as given in *Building Intelligence*, embraces in number

83 BUILDINGS OF THE VALUE OF $635,411.

The movements in real estate, as reported in the daily journals, that sales are light, would indicate a falling off in property interests. But when the high prices asked for real estate, the almost boom in building during the past three years, the damaging rains late in the season, the disturbance in financial circles by failures, shrinkages of values, etc., are considered, the present looks well, and the future encouraging.

The considerable decline in cost of lumber, bricks, nails, and other building materials, should, and we believe will, stimulate to enlarge activities during the remaining months of the year.

San Francisco Chapter American Institute of Architects.

THE regular monthly meeting was held on Friday evening, August 1, 1884.

President John Wright in the chair. F. Marion Wells was unanimously elected an honorary member of the Chapter.

A lengthy communication, signed by nearly all the members of the craft residing in San Francisco, was received from the Metal Roofers. In it, they called attention to the fact that metal roofing is a distinctive branch of trade, and should not be done in shops in which the proprietor conducts the various industries of plumbing, gas fitting and tinning, combined with metal roofing. The petition represented that the parties referred to do not have enough work at any one branch of business, and so have to keep on men who can do a little at anything, and from necessity they must be inferior workmen. The remedy proposed in the document, is to recognize metal roofing as a distinct branch of the trade, and to allow only metal roofers to figure on their branch of work.

Communications were also received from the Master Plumbers and Painters' Association, calling the attention of the Chapter to a clause in their by-laws, by which their members are prohibited from doing work for other than owners when the amount exceeds $100 in value.

Also communication received from J. Browell in reference to patent chimneys. All the above were ordered placed on file.

The amendment to the by-laws was unanimously adopted, by which the number of Trustees was increased from three to five.

The following preamble and resolution was offered by J. E. Wolfe, who explained that its intent was to set at rest any doubts that may be entertained upon the subject.

WHEREAS, Some diversity of views and opinions are entertained by members of this Chapter in reference to the eligibility to membership of one member of a firm of architects, unless the other member of said firm seek membership, therefore be it

RESOLVED, as the sense of this Chapter, that individual members of co-partnership firms of architects, upon election to membership in this Chapter shall be entitled to affiliation without regard to the wishes or action of the other member or members of said firm in the same direction.

After a short debate, the resolution was unanimously adopted.

Nomination of officers for the ensuing term being in order, the following named gentlemen were proposed.

President: Augustus Laver, William Curlett.

Vice-President: T. J. Welsh, A. Pissis, and H. C. Macy.

Secretary: B. E Henriksen, G. H. Wolfe.

Treasurer: J. M. Curtis.

Trustees: J. E. Wolfe, A. A. Bennett, B. E. Henriksen, W. Curlett, W. G. Matthews, G. H. Sanders, T. J. Welsh, A. Laver.

The resignation of W. G. Copeland was read and accepted.

The following resolution was offered:—

That a committee of five be appointed to take into consideration the Fire Ordinances of San Francisco, and report at next meeting.

A long debate ensued, which was participated in by nearly every member present. The subject was dropped until a report was received from the Committee.

The president appointed the following named gentlemen to act as such committee: Messrs. J. E. Wolfe, J. M. Curtis, Wm. Curlett, T. J. Welsh, B. E. Henriksen. Meeting adjourned.

IMPORTANT NOTICE.

The next meeting of the Chapter will be held on Friday evening, September 5, 1884. It is earnestly hoped that every member will be present, as business of more than usual importance will be brought before the meeting.

The Fire Ordinances of the City of San Francisco.

MUNICIPAL laws and regulations should in themselves be as nearly perfect, fair, and equitable as human intelligence, experience, and judgment can make them; and being so, should be cheerfully accepted and followed by those whose interests are covered or affected by them; and in all cases of violation, their enforcement should be positive, equal, and without favor or partiality in any direction, or to any person or persons whomsoever. But neither of these propositions apply in the case of the present and more recently passed code of fire ordinances in San Francisco. Although in their provisions they are very similar, and in some respects the same, as those of Chicago and other Eastern cities, they do not provide a code of regulations so nearly right and applicable for San Francisco as to meet with a reasonable degree of favor from those who are required to be governed by them; and the fact that *very many* of their requirements are so far unnecessary and impracticable that they are *never* observed by architects, nor sought to be enforced by the authorities—while in some regards, the limits and restrictions are unreasonable, unnecessary, and disproportionate, and the privileges enjoyed by some, more than is permitted to other owners and architects, naturally give rise to loud complainings, and suggest at least the wisdom and necessity of revision.

In view of the facts hinted at, the San Francisco Chapter of Architects have appointed a committee of five, consisting of James E. Wolfe, J. M. Curtis, Wm. Curlett, T. J. Welsh, and B. E. Henriksen to consider the ordinances as affecting and relating to the erection and safety of buildings, and report thereon to the Chapter, the object of which is simply to review and discuss all matters in issue and interest, and submit to the proper authorities, for their consideration and action, such recommendations as may be finally agreed upon and advised by the Chapter.

The Chapter and its committee recognize the fact that the present code of fire ordinances is the result of much perplexing attention, study, and personal, mental, and physical labors; and no reflection is deserved by those originating and recommending the present laws, as whatever defects there may be have been innocently incorporated.

In behalf of the Committee and Chapter, we are authorized to state that *all architects*, whether members of the Chapter or not, are earnestly requested to forward to either member of the committee, such pertinent points of information, facts, and suggestions as will aid the committee in perfecting their work. And as the object of the Chapter in the appointment of the committee is to secure the best possible results, *all members of the profession*, together with the fire wardens and representatives of the Board of Underwriters, will be invited to take part in the final action upon the report of the committee.

Not Degenerating—Times Have Changed.

EDITOR *Building Trade Journal:* "Ransom," in his communication in your last issue, asks the question, "Is carpenter work degenerating?" and then to some extent answers it himself, but fails to state the cause for the facts he alleges. He also objects to "the saw and hatchet brigade who lack the knowledge of good mechanics." The truth is that in the present day it is quicker and cheaper to get mill work in a city of any considerable size than to make the same work by hand as in old times. No carpenter in a city now thinks of lugging about a two or three hundred pound chest of tools, consisting only of moulding, sash, and match planes, as many in the country did in former years, in addition to the ordinary chest of tools which came into everyday use. Nowadays fine office and store fixtures and much other work comes from the mill in such shape that a couple of ordinarily clever workmen with only a shoulder box full of tools between them will put it up more rapidly and fully as well as did the thoroughly trained carpenters of old times after making the fixtures by hand. The proportionate number of carpenters who are "good wherever you put them," is decreasing from this and the fact that when a man finds himself particularly fast and good at any particular branch of the business, he follows that in preference to any other and finds it more profitable to do so. A saw and hatchet brigade with very little experience and a natural aptitude for handling these useful articles can lay as much flooring in a day as the same number of skilled carpenters who have served an apprenticeship of years, and if the skilled workmen have grown gray in the service they will probably find the others outworking them. A builder who pays a skilled workman $3.00 a day for such work cannot compete with another who gets as much or more work from each man and employs men who know nothing but this at $2.25 to $2.75 per day. It is true that in this case the last-mentioned builder must keep a few skillful men to do the finer work, but in a city where the buildings are mostly brick or stone, the work on them, such as laying joists and flooring, is hardly deserving of the name of carpenter work. The builders do not want to remedy, as "Ransom" expresses it, "this great trouble," nor have they any object in keeping one or two apprentices about their shops when at any time they want them an advertisement will bring them a hundred men. When the supply of carpenters so greatly exceeds the demand that the wages of good workmen are actually less than those of hod carriers, I cannot see the advantages of apprenticing a boy to the trade. It seems to me that "Ransom's" idea is that, for the advantage of builders, apprentices should work for years to acquire the necessary skill, accumulate several hundred dollars' worth of tools and then hunt for work a considerable part of the time without finding it. Many of the things they learned during their apprenticeship, within five years, would be entirely useless, from the fact that improved machinery would do better and cheaper work than they could. Builders and carpenters know this, and the carpenters who have apprentices, too often have to put them to making ironing boards and shining boxes during dull seasons. What is more necessary than more apprentices, is that men claiming to be skilled workmen spend less time in talking of how twenty years ago they worked for three months getting out the sash for Col. Jones' house in Bungtown, "all made by hand, sir," and apply their leisure to learning to use advantageously tools and appliances unknown when Col. Jones' house was put up in Bungtown.

H. G. C.

DON'T DELAY REPAIRS.—We once worked in a shop where a specialty was made of builders' finish, brackets, mouldings, fancy finish, etc. About eight hands were employed in the room we worked in. The machinery consisted of railroad combination, band and jig saws, panel and buzz planer, a boring machine and a two-spindle moulder. The two planers and the jig saw had loose pulleys which were so badly worn as to necessitate throwing off the belts from the main shaft to the counter every time each machine was used. In that shop each man took an order from the order book, got out his stock, and finished the job, using whichever machines were needed. When it was necessary to use the panel planer we had to climb up on the jig saw table and throw on the belt; when the buzz was needed, the planer must be used to stand on, in order to get at the requisite belt. If the planer was running it must bestopped, thus delaying the man who was running it. One day after getting thoroughly disgusted we "went for" the boss and asked him if he was going to have those pulleys bushed this year. He said he was going to "just as soon as he got time," but he let them run in this way for two whole months. One day we noted the number of times we had to throw on and off those belts. We used the planer 15 times, the buzz 10 and the jig saw 16 times, making 41 times in all. It took about a minute to put on, and another one to throw off a belt, thus taking in all 82 minutes in one day. There were eight of us who had to do the same thing, so it took 656 minutes or about 11 hours to handle those belts—more than one man's time every day. Running this way for 9 weeks would amount at the rate of 40 cents per hour to $212, and our boss could not find time to have the pulleys fixed. We showed the figures to him one day. He scratched his head, took them into the office, and ten minutes afterwards came out, shut down the shop instantly and sent those counters and pulleys to the machine shop. A loose pulley that rattles has not been seen nor heard in that shop since. You may go into every shop in the land and six out of ten will have one or more of these "hand shippers" in operation. How is it in your shop? If the coat fits put it on.—*Cabinetmaker.*

California Redwood; Will it "Shrink," "Warp," and "Crack"?

REDWOOD being a lumber product special to this State, it is gratifying to read favorable notices in Eastern and foreign journals as to its good qualities, when such notices are fairly, if not strictly within the range of exact facts; but when they go beyond this, and state more than is warranted by the actualities of the case, they become misleading and creative of wrong notions and conclusions, and in the long run work an injury not compensated by any temporary good effect produced by overstatements calculated to stimulate a demand on the part of manufacturers in distant places for a wood of the very superior and exceptional character ascribed to the redwoods of the Pacific Coast.

We refer to this matter, owing to the fact that the following statement has been freely circulated in the journals of this country and of Europe, to wit: . . . "*The fact that redwood neither* WARPS, SHRINKS, *nor* CRACKS, *should lead the attention of furniture manufacturers to practically examine into its merits, and if found satisfactory, the distinct branch of business referred to would receive a valuable addition from the forests of California.*"

The foregoing is only qualified correct. If redwood in real fact possesses all the qualities accredited to it by our contemporaries, it would certainly be entitled to most favorable consideration, for, as yet, there has never been a wood found entirely free from the defect of shrinkage, nor can that quality be claimed for the redwood of California, in an absolute degree.

As the result of thirty-three years' practical, personal experience in the use of redwood in connection with house and other constructions, and close observation and practical experiment in furniture and many other things calculated to develop the specialties of redwood, we give the following, which may be relied upon as correct for all practical purposes.

It should be first stated that like all other woods, the product of all trees of the same specie is not of equal grain and quality, the great bulk of redwood being from *good* to *excellent*, with occasional trees yielding brash, hard, springy boards and cuts. Consequently much of that used for general purposes, in the way of scantling, posts, fence boards, for the erection of wood bulk heads, etc., is devoid of all the credits expressed in the extract under notice.

As to "shrinkage," there is a quality of redwood, which, when *properly seasoned*—water seasoning being decidedly advantageous—and thoroughly dried after such seasoning, will equal, if not excel any other lumber known, in the matter of non-shrinkage, while the redwood lumber *generally* used in house construction will shrink, both in width and length. It is a very common thing to see the butt joints in rustic and wall boarding on frame buildings, the sheathing on inside walls, ceilings, etc., shrink open before the completion of the structure, in boards of twelve, fourteen and sixteen feet lengths, all the way from small open joints up to one quarter, and in some cases half an inch. So that all *unqualified* statements made that redwood lumber will not shrink are erroneous. But at the same time we wish it understood that picked redwood lumber, properly treated, has no superiors in a shrinkage point of view.

Will it "crack"? That depends upon the quality, the condition of the lumber, and the position in which it is placed. It being a rather soft, light material, it is far more liable to fracture lengthwise than the generally known lumber used for building purposes in this and other States. But its liability to "crack" is not such as to lessen its value as a building material, both for outside and inside finishes.

As to its "warping," with the exception of a specially hard, brash kind, pieces of which are to be found in almost all promiscuous lots, it is specially free from this defect; and when nailed in place, as on fences, etc., it "stays where it is put."

As a "finishing" lumber, its use has been and is almost universal in California, both for inside and outside work, as it is the cheapest in cost, and more easily worked than any other, and answers all the usual purpose for architraves, wainscoting, and trims and finishes generally, and for door panels; but owing to its greater brittleness, seldom used for the stiles and rails of doors. In the better class of buildings, "hard" and more expensive woods are sometimes used, but seldom to the entire exclusion of redwood.

As a "furniture" material, it has its special qualities. Root and snarly redwood veneers, and some of the wavy, curly pieces will bear comparison for beauty with most of the highest cost hard woods. Much of the very handsome and costly furniture manufactured in this State, have some of the parts of selected California redwood. There is perhaps no wood on earth that will hold glue better. In the manufacture of veneered and other glued joint work, it is recognized as incomparable for its tenacity for holding. It is susceptible of any degree of high polish, and owing to its porous character receives and holds paints well. But while it is good for numerous *tender* uses, it is a poor material for floors and other purposes, where subjected to friction or hard wear and tear.

A NEW process for drying lumber is just now attracting attention. It is said to be the most effectual and economical method ever practised. No kiln is necessary, although where a shop has one it can be utilized to advantage. The process has the great advantage of keeping the surface of the lumber moist during the drying; this holds the pores open, obviates all tendency to cracking and leaves the albumen free to perform its natural functions. In ordinary kiln drying the albumen is injured or destroyed, and the surface dries first, thus sealing the juice inside, to escape eventually through cracks caused by the uneven expansion of the wood. The statements in circulation as to the remarkable cheapness, simplicity and thoroughness of of this new method seem to merit the attention of every builder and wood worker, for it is described as being equally well adapted to large and small shops. Some readers may perhaps be surprised to learn that the process consists in surrounding the wood to be dried with common salt; but those who are acquainted with the peculiar power for extracting moisture which salt possesses will not be at all astonished at this novel and ingenious utilization of this power.

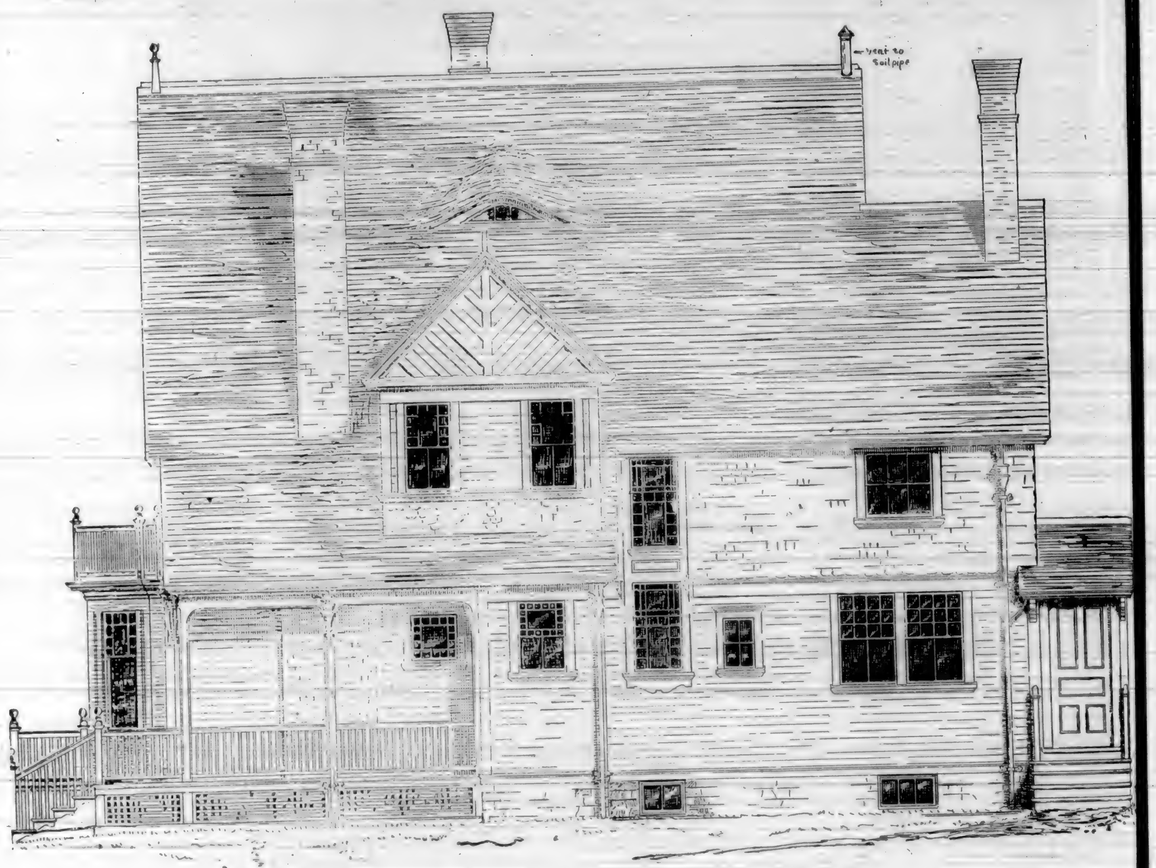
Hand and Machine-made Putty.

How the two kinds are made, and the difference between them, is related by an old painter to the ubiquitous reporter of an American contemporary as follows:—

The best is made of raw linseed oil and whiting, the latter being simply chalk, ground in a mill like flour. It comes out with a fine flint grit in it. Before making putty of it, a few old-fashioned men who believe in making the best of everything, wash the grit out. The fine flour is then dried. If it is not dried perfectly, it takes up more oil than is desirable or profitable. From 500 to 600 pounds—about 15 per cent. by weight of raw oil to 85 per cent. of whiting—are put in a chaser and thoroughly mixed. The chaser is an annular trough, ten feet in diameter. From a vertical shaft in the center two arms extend, on the ends of which are heavy iron wheels that rest in the trough. When the shaft revolves, the wheels chase each other around the trough. When mixed, it is packed in bladders for convenience in handling. The adulteration of putty is effected by mixing marble dust with whiting. It costs about a quarter of a cent a pound, and whiting costs twice that. Paraffine oils, at from 10d. to 1s. a gallon, are used instead of linseed oil at 1s. 6d. The marble dust makes the putty gritty, and the cheap oil makes it sticky. Cheap putty is decidedly cheap. Putty in bulk, wholesale, is worth 8s. 6d. a hundred pounds. The other window glass cements run from 4s. 6d. to 4s. 9d. They are dear at that. They take longer to put on and longer to dry. Putty is neither imported nor exported. A lot was brought over a long time ago, but that was when oil was very high. The whiting comes from England.

A superior article of putty is made, however, by the further addition of white lead in oil, Japan varnish, and a small quantity of turpentine, which makes a hard cement that does not shrink, and when dry can be rubbed down with pumice stone or dusted with sand paper, so smoothly will it cut. Even in the common sorts of putty it is well to use some white lead if a hard putty is desired.

Every mechanic, property owner, material man, etc., should subscribe for the California Architect and Building News. Terms, $[illegible] per annum.



SIDE ELEVATION OF $5,000 COUNTRY DWELLING.—FIRST PREMIUM DESIGN.

Our Competitive Designs.

NUMBER ONE.

THE accompanying design and plans on this and other pages of this issue, are those to which was awarded the first premium by this Journal, in the late competition for plans of a country dwelling to cost about $5,000. The author is Junius H. Morse, of Boston.

The style of architecture presented is essentially different from that generally adopted on this coast. We leave it to our readers to form and express their opinions in regard to the adaptability of the elevations shown, to meet the requirements of different localities.

The plans show very careful study on the part of the author, and credit is due him for the thorough and artistic arrangement of the rooms and the detailing of so many conveniences. In the latter item, the plans excel any which have come under our notice.

It will be noticed that an alternate plan is shown on page 142. By comparing it with plan on page 143 it will be seen that though presenting the same general arrangement, it is of more practical utility, inasmuch as *direct* communication is established between the dining and sitting-rooms, thus obviating the necessity of entering the dining-room by the way of the main hall.

The plans are so plain, that we do not deem an extended notice necessary. The following specifications by the author will sufficiently explain his ideas:—

BOSTON, April 12, 1884.

A memorandum of the kind of materials to be used, and quality of work to be performed in building and completing a country house after plans furnished by "As you like it."

EXCAVATION.

Excavate the cellar four feet deep under whole of the house, the dirt removed to be used in grading around the house. Stack the loam in a separate pile. Excavate for all drains and cesspool.

FOUNDATION.

Cellar wall eight feet (8) high to be built of sound, large, field or ledge stone, well bonded and laid in one-half (½) cement mortar. Face wall on the inside and outside above grade, the joints to be neatly struck on the outside. Furnish footing stones for all piers and chimneys, and build a dry drain around the outside of wall.

BRICKWORK.

Build chimneys of good, hard, burned brick selected for exposed parts, all to be laid in one-half cement mortar; tops to be colored with Venetian red. Flues 8x12in. Use Philadelphia face brick for fire-places; glazed tile hearths in first story, unglazed tile hearths in second story.

FRAME.

Regular braced frame of clear sound seasoned spruce, sills 6x7in.; studs, 2x4in.; posts, 4x6in.; girt, 4x6in.; plate, 4x4in.; girders, 6x8in.; first and second story floor joists, 2x10in.; third story floor joists, 2x9in.; all set, 16in. on centres; rafters 2x8in.; set 20in. on centres.

FRONT ELEVATION OF $5,000 COUNTRY DWELLING.—FIRST PREMIUM DESIGN.

BOARDING.

Use sound seasoned hemlock boards for roof, walls, and under floors. Pine tarred sheathing paper to be put under all shingles, clapboards, and between all floors.

OUTSIDE FINISH.

Outside finish to be first quality seasoned pine. Roof and wall shingles best cedar, sawed fancy cut where shown. Clapboards clear sound spruce, laid four inches to weather. Pine gutters. Zinc conductors with fancy heads. Use lead and zinc flashings around chimneys and exposed places.

GLASS.

Windows glazed with first quality double thick German glass, single thick for all small lights, bevelled French plate for front door. The upper sash of staircase window to be leaded, stained glass.

WINDOW FRAMES AND SASH.

Pine sash stained, 1¾in. thick; 2in. pine sills hard pine pulley stiles, galvanized iron pulleys, iron weights hung with hemp cord. Blinds first quality half roll.

TOP FLOORS.

Hard pine for kitchen, pantry, china closet, and piazza floors. Halls, vestibule, and dining-room, oak borders with spruce centers. Bath-room, cherry. The parlor, sitting-room, chambers, and closets, spruce; all floors to be hand planed after being laid, and no board to be over four inches wide.

MANTELS.

$125 allowed for four mantels and six shelves.

INSIDE FINISH.

The first story bases 8in. high moulded, architraves reeded 4½in. with back band, turned corner blocks, plinth. Second story 7in., base 4in., moulded architrave with plinth. Second story 7in. base., 4in. moulded architrave with plinth and turned corner blocks. Third story and kitchen 6in. chamfered base, plain 4in. architraves with corner blocks. The parlor, sitting-room, and two principal chambers in pine, one coat shellac, two coats lead and oil selected colors. The hall and dining-room in oak. All other rooms in white wood two coats shellac rubbed down in oil. Hall dado 3ft. 6in. high, dining-room dado 3ft. 0in. high, raised panels with flush mouldings.

DOORS.

Outside doors pine 2in. thick. First story five panels 1¾in. thick, whitewood veneered to match the finish of rooms they stand in. Second and third story 1⅜in., five panels; all to be hung on lifting butts.

PLASTER.

Best two coat work on spruce laths, cork floated in hall and vestibule to be painted. A small plaster cornice in parlor, two centres.

PAPERING.

Allow $150 for wall papers and papering.

PAINTING.

Roof shingles two coats lead and oil Indian red, creosote stain for second story shingles warm sepia. First story clapboards three coats of lead and oil, Pompeian red. Trimmings dark bronze olive green, three coats. The painter to glaze all the windows, finish all hard wood, and do all the interior painting.

FURNACE.

The sum of $150 is allowed for a furnace.

HARDWARE.

The contractor to furnish all locks, knobs, butts, screws, nails, hinges, sash fasts, pulls, snaps, hooks and catches; furnish the iron brace for front chimney.

BELLS AND TUBES.

Bell from front door to kitchen, one on side door; foot bell from dining room to kitchen. A speaking tube from second story hall to kitchen.

STAIRS.

Front stairs pine risers and treads, oak rail 6in., newel post 4½in., angle posts 1½in., balusters fancy turned. Attic and back stairs pine.

PLUMBING.

One bath-tub, seat, and bowl in bath-room, one sink, boiler, and two set tubs in kitchen, a water-closet in cellar; a first-class job in all respects, done according to the Boston building laws.

MISCELLANEOUS.

Build coal bins, pipe for gas, put shelves, drawers, and hook strips where directed by owner.

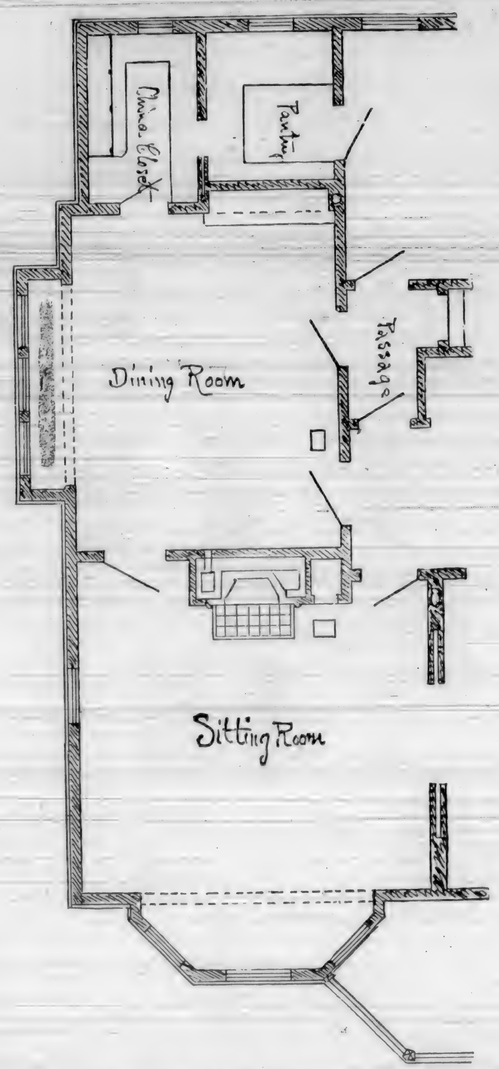
GENERAL CLAUSE.

The work is to be done in a thorough and workmanlike manner, and all breakages and marring of work to be made good by the contractor.

In the accompanying estimate it must be borne in mind, that prices given are those at present ruling in the city of Boston, and are not, by any means, to be taken as those for which the same work could be done on this coast. A decidedly much higher estimate must be allowed for the plan as presented, should any one see fit to adopt the same and erect on this coast a building in conformity to the plans.

It was our intention to prepare a California estimate, so our Eastern subscribers could compare the cost of work and material on the two extreme ends of our country. We found the task rather difficult, without completely changing the looks of the front. The principal difficulty lies in the fact, that here, in houses of the cost given, the stories are seldom, if ever, less in height than 12 feet for first story, and 11 for second; these proportions would be exceeded in houses in which rooms are as large as those shown. By reference to the front elevation, it will be seen that the height of stories is but 8 and 9 feet. It is obvious that an increase of those measurements to those used here, would materially effect the appearance of the outside, as windows, doors, etc., would all have to be larger than shown.

It will be noticed that the price of rough lumber in estimate, is much lower than that ruling here, while that of finish lumber is higher. Brick work, plastering, plumbing, painting, and mantels, are all considerably lower than the amount for which said work could be done in this city. A careful study of the estimate will enable one to contrast the difference.



ALTERNATIVE DESIGN SHOWING DIRECT COMMUNICATION BETWEEN SITTING ROOM AND DINING ROOM.

ESTIMATE OF QUANTITIES AND PRICES RULING AT BOSTON, MASS.

MASON WORK.

250 cu. yds. of excavation @ 25 cents	$ 62 50

FIRST STORY PLAN OF $5,000 COUNTRY DWELLING.—FIRST PREMIUM DESIGN.

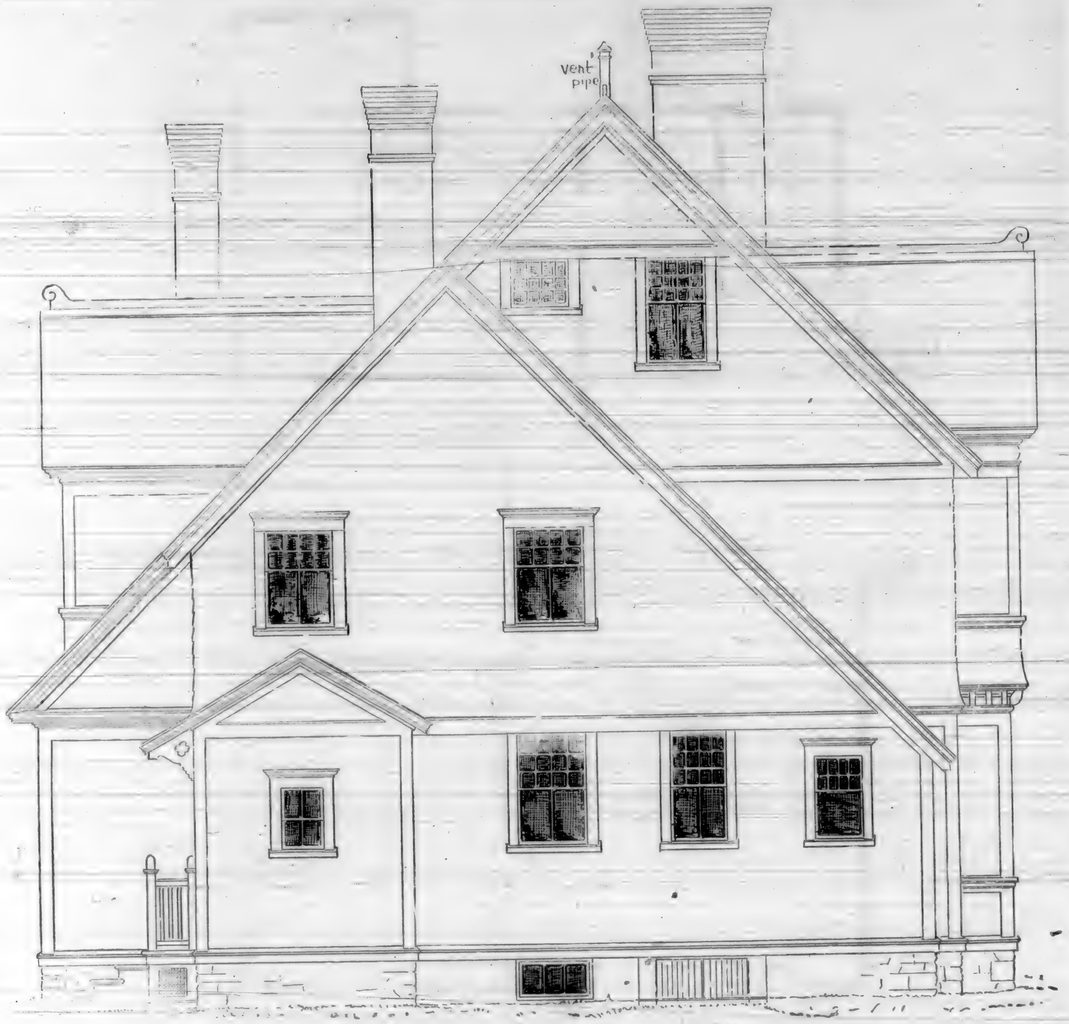
CARPENTER WORK.

12,000 ft. of spruce framing timber @ $16 per M	$192 00
3,000 ft. of furring and partition stock @ $16 per M	48 00
9,500 ft. of hemlock roof and floor boards @ $12 00	114 00
30,000 ft. of sawed cedar shingles, wall and roof, @ 4.50	135 00
1,200 ft. of spruce clapboards @ $30 per M.	36 00
Sheathing paper	50 00
2,500 ft. of pine outside finish @ $60 per M.	150 00
80 ft of wood gutter @ 12 cents	9 60
3,180 ft. of spruce floor boards @ $25 per M.	79 50
700 ft. of hard pine rift sawed @ $50 per M	35 00
500 ft. of pine inside finish @ $60 per M.	30 00
1,500 ft. of whitewood inside finish @ $60 per M.	90 00
100 ft. of panelled dado @ $1 per running ft.	100 00
70 ft of zinc conductor @ 15 cents	10 50
Windows complete	300 00
Doors and frames complete	290 00
Hardware and nails	250 00
Stairs, rail-posts and balusters complete	225 00
Plumbing complete (an actual estimate)	325 00
Painting complete	300 00
Mantels and shelves	125 00
Papering	150 00
Furnace set ready for use, pipes, etc.	150 00
Carpenters' labor	825 00
Total	4,019 60
Mason work	$1,105 50
Total	$5,125 10

Architects' commission not included.

Respectfully submitted,

"AS YOU LIKE IT."

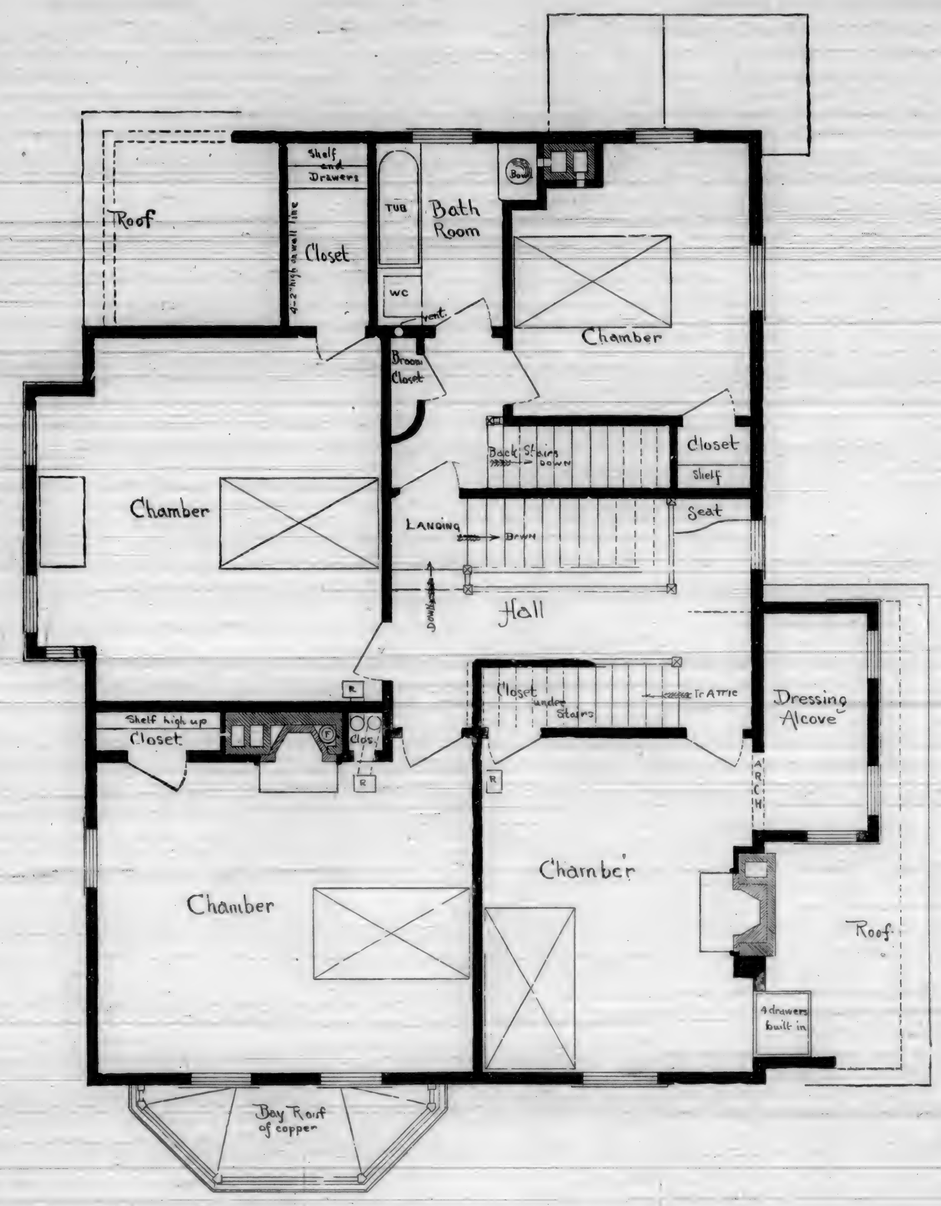


REAR ELEVATION OF $5,000 COUNTRY DWELLING.—FIRST PREMIUM DESIGN.

Mechanics should remember that it is for their interest to forward items of general interest to the publishers of this Journal as, by so doing, they reap much benefit from an interchange of ideas. If engravings are necessary to explain your ideas, send a rough sketch of the same and we will put them in a presentable form.

AN ORIGINAL RAT TRAP.—This trap consists of a sheet iron pipe with a sort of rim on both ends and a strong two-bushel sack tied firmly around one end. Every hole is stopped in the corn-crib but one, which opens into a feed box on the other side of the partition. Then the pipe is placed in the feed-box and fitted, the open end firmly over the hole, allowing the sack to hang over the edge of the box into the manger. The trap prepared, the door of the crib is left open and the rats permitted to have their own way for an hour or so. Then the door is shut and a noise made to frighten the rats. Having but one means of escape they rush into the pipe and down into the sack, where they are easily caught.

Owing to the great increase in our circulation, causing great demand for advertising space, we have to announce an increase in the rates established January 1, 1884. We are continually receiving letters from parties, in regard to advantages secured by an advertisement in this Journal. Our rates are now $50.00 PER PAGE FOR SINGLE INSERTION. Proportional rates accordingly for smaller spaces.



SECOND STORY PLAN OF $5,000 COUNTRY DWELLING.—FIRST PREMIUM DESIGN.

A New Work. How to Build, Furnish and Decorate. Price $5.00. Send to This Office.

Our Sewerage System and the Cholera.

As USUAL in all cases of alarm or anticipated approach of contagious disease or possible epidemic, the sewerage of San Francisco looms up as a formidable agency of evil, in view of the cholera scare at present so general in many parts of the world; so much so that from the health department comes the warning that something should at once be done by the city government to cleanse and purify those underground conduits, which at all times contain and emit the germs of disease. And in view of the terrible character of the special agency of death, which has recently appeared in parts of the Old World, and is reported to have crossed the Atlantic, and shown itself in the metropolis of the United States, it is but natural that not only the head of our health department, but every citizen of this commonwealth should scrutinize closely as to the more probable channels of approach and danger to San Francisco.

And as it always has been, so it is now—the sewerage of the city is about the first in mind, because it is well understood to be about the worst in the world, all things considered; for there never was a city located anywhere on the earth's surface where the natural contour of the surface of the land was more favorable to perfect drainage, than the original limits of the city inside of the filled-in districts. And had good and wise judgment, and skillful experience, and intelligent civil engineering been practiced in establishing the grades of the streets, and consequently the grades of the sewers, they would to-day be a source of pride, as perfect for all the purposes for which they are intended, rather than as they now are, a source of dread and alarm, causing uneasiness and fear among the people,—a something that should by all means be specially guarded against at times like the present, when the feeling of perfect safety from all local causes of infection should be universal in the community. For it is a conceded fact that fright and fear has much to do with the spread of epidemics.

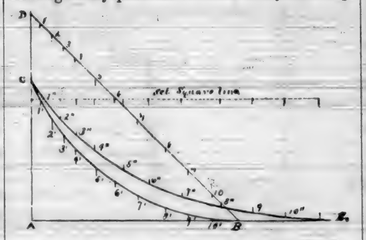
But the frequent reference to the sewerage of the city by the health officials has become rather monotonous, inasmuch as it fails to produce the proper action corrective of the evil. The naming and pointing out, or the strong denunciation of a bad thing, however often or forcibly repeated, amounts to nothing, unless productive of proper action; and so long as the magnitude of the sewer pest in San Francisco is overlooked, and those whose duty it is to correct and perfect the same, take no proper interest or action in the matter, health officials may sound the alarm until doom's day, while the cholera or any other malignant disease may enter the gates of the city and carry off their victims with impunity.

A floor-area of ten square feet to each occupant of a sleeping apartment is necessary to an adequate supply of air for eight or nine hours of slumber.

SAN JOSE, May 30, 1884.

To the Editor of the CALIFORNIA ARCHITECT:—

Mr. M. J. Marion has given to your readers the true theoretical way of finding a curved hip or diagonal rafter; allow me to present a way I have thumbed out for myself, it often coming in my practice to have to lay off a hip.



Let A B be the seat line of the rafter and C B the elevation of the same. Draw D B at the same angle to A B that the seat line of your hip rafter will bear to the seat line of your square rafter, cutting the perpendicular A C produced in D. Now tick off ordinates 1' 1'' 2.2'', etc. parallel to A D, cutting D B and C B in 1'. 1'' 2'. 2'' 3. 3', etc. Now take a set square or straight edge with a square end and lay the long edge on the line D B with the square corner at D, mark off the ticks 1, 2, 3, etc. on the edge of set square (as per square enclosed), clamp down a straight edge on A D and slide your marked square on it as shown; with the edge of the set square passing through 1' mark off the position of the tick 1'' on the set square at 1''. Continue this at 2'' 3'' to F. Spring a batten through the spots 1'' 2'', etc., so obtained, and draw your hip rafter. This though seemingly complicated, once understood will enable one to draw such a rafter in one third the time, and what is also important one third the space occupied by Mr. Marion's method. ONLY A CARPENTER.

Personal.

TO THE host of kind friends who have so cordially and heartily—by word and pen—extended to us wishes of joy, good health and long life, we return our sincere thanks, pledging that, should like happy conditions at any time in the future, surround any of them, our hand, voice and pen will be utilized to return honestly expressed salutations and greetings, with the wish that those who follow our example may be alike successful with ourselves in selecting an antidote for the loneliness of single unblessedness.

IN regard to the durability of the different woods, the most odoriferous kinds are generally esteemed the most durable; also the woods of a close and compact texture are generally more durable than those that are open and porous; but there are exceptions, as the wood of the evergreen oak is more compact than that of the common oak, but not nearly so durable.

Make your own Gas.

OWNERS of country stores and dwellings should use every precaution against fire, as the non-proximity of fire engines and scarcity of water oftentimes causes a small fire to develop into a disastrous conflagration. Since the first introduction of coal oil as a means of illumination, various contrivances have been placed in the market by which gas could be manufactured from that substance. For more than twenty years improvements have been made in gas machines, until there has been developed one that is as near perfection as scientific study and investigation can produce.

These machines are guaranteed absolutely safe in their operation, simple in construction, not liable to get out of order, and require no skill to manage. They require less attention than a common kerosene lamp. *No fire is used in the process of manufacturing gas by these machines.* Cost of gas will be less than one dollar per thousand feet.

The tank, containing the gasoline, is buried in the ground and is delivered in permanent pipes and fixtures to the proper distributing points. Consequently no danger or trouble is engendered by frequent removals of the fluid. Full particulars in regard to these machines will be given by addressing A. F. Nye & Co., 609 Market Street, San Francisco, who are the sole agents for the best machine manufactured.

Modern High Explosives.

IN presenting this work to the public, the author has endeavored to acquaint the engineer, the contractor, and the chemist, with the composition of the substances they are now so largely using, with their peculiar characteristics and their adaptation for certain results; or in a word to familiarize them with the high explosives. Extra business engagements have prevented us giving time for a thorough examination of the contents of this work, but from a cursory view it is written in a style at once attractive to those for whom it is intended. Our library is always open to those who desire to examine the latest works, and we will take pleasure in showing the above to those who call.

THE day is past when people are contented with mere box-like houses, and every one tries to make his home as attractive to the view as possible. A small amount of ornamentation, properly applied, will not add to the cost of a building, while it greatly relieves the monotony of appearance by breaking the surface into light and shadow, and will always speak more in favor of the fine taste and feeling of the owner than an overloaded ornamentation. Keep this in mind: simple, well-proportioned forms do more to beautify than a confused mass of adornments poorly distributed.—*The Builder and Wood-Worker.*

Prosper Huerne.

MR. PROSPER HUERNE, whose likeness is here given, was born at Pontgouin, near Chartres, France, November 26, 1820, and obtained an education as civil engineer in the Government school of *Arts et Metiers* at Chalons.

He early commenced his professional career by constructing a section of the Orleans Railroad, together with the necessary depots, and later, after having been admitted as *Ingenieur Conducteur* in the *Corps des Ponts et Chaussées*, he erected, as assistant chief engineer, the great bridge over the River Loire, for the Central Railroad. At the time of the great inundation of the Loire in 1846, he distinguished himself for his bravery by saving the lives of a great many persons, at the imminent risk of his own. For this service the French Government awarded him a medal of honor.

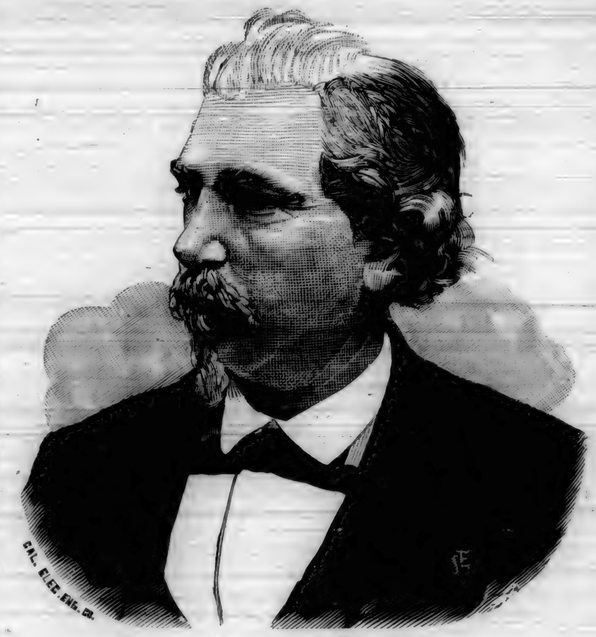
Believing that this country offered a more promising field for advancement than his native country, he decided to start for California, and landed at San Francisco the 17th of June, 1850.

His career here has been a busy and useful one. He designed and constructed the North Point Docks in 1854, and three years later built the French Hospital on Bryant Street. The Market Street Railroad, the first railroad in the city (running to the Mission Dolores), was equipped and run under his directions, he being the chief engineer and assistant superintendent. In 1866 he presented, in competition, a project for the San Francisco Harbor Sea Wall, and of the thirty-three designs submitted, his was ranked second.

The first sugar refinery erected by Claus Spreckels on Eighth Street, the new church at the Mission Dolores, destined to replace the adobe structure built by the early missionaries, and numberless business edifices and private residences in this city, and churches and colleges all over the coast, attest that his ability as an architect is not inferior to his skill as an engineer.

In the latter capacity he has long been of service to the French Government, keeping her informed, through her consuls here, on many details of our local progress and improvement. Under this head he has described in detail the organization of our admirable fire department, by special request written lengthy reports on the harbors of San Francisco and San Diego, and on frequent occasions brought to the notice of foreign engineers the system of cable railroads, as perfected here, furnishing plans and illustrations of this and of other interesting achievements for publication in the various French scientific periodicals.

He has (in connection with Slaven Bros.), devoted his energies to sharing in the execution of the great enterprise of his celebrated countryman, Ferdinand de Lesseps. As architect, he erected the large storehouses and many of the buildings necessary for the accommodation of the great number of engineers and employés now laboring on the Isthmus of Panama. As engineer, he is now occupied in connection with a powerful New York company in carrying out a contract with the *Compagnie Universelle du Canal Interocean-*



PROSPER HUERNE.

ique, to dredge the Atlantic side of the above canal.

He is a member of the San Francisco Chapter of the American Institute of Architects, the California Academy of Sciences, the Exempt Fire Company, the Territorial Pioneers, and other prominent societies. One other item in connection with Mr. Huerne's career is of especial interest, viz., he is the living pioneer architect of San Francisco.

Ignorance in the Use of Stoves.

STOVES are among the commonest and most useful things in the world, and yet a family will use an ordinary cooking range during its natural life-time and never know its flue construction. Stove manufacturers and dealers will bear us out in saying the greatest difficulty they have to contend with in the introduction of stoves is the ignorance of the people who use them. This is illustrated by a recent incident in the experience of a Pittsburg house which was told us a few days since. One of their standard ranges was placed in the house of a physician, and the complaint came that it was impossible to bake with it or heat water by the water-back. A representative of the house went to investigate the matter and says he didn't do a thing to the range but build a fire in it. When he started the fire in it, and baked potatoes in twenty minutes, the doctor's people became convinced that the range would bake if given a chance. It took longer to heat a thirty-gallon tank of water but it was accomplished in a reasonable time. There was nothing the matter with the range, nor even with the chimney.

The trouble was that the people had been trying to force the range to consume coal instead of to do its duty in baking. The stove man remarked to the physician that when he gave his patients physic he did not give them too much. The range would work all right if treated in the same way. Give it coal in even homeopathic doses and it would accomplish the result desired. People are coming slowly to learn that a stove can be made to do efficient service with a small amount of fuel. This is especially true in the use of hard coal. Stove dealers can benefit their trade and do a favor to customers by becoming thoroughly familiar with the working of the stoves they sell, and explaining their construction and instructing their patrons how to use them properly. By so doing stoves and ranges will be made to give better satisfaction, and there will be less complaints.—*Tinner and House Furnisher.*

Cottages—Another New Work.

THIS new work contains twenty-four plates of medium and low cost houses, by different architects, together with descriptive letter-press, giving practical suggestions for cottage building, to which is added a chapter on the water supply, sewerage, drainage and other sanitary questions relating to country houses. The work is the best one that has, as yet, been presented before the public for the price quoted. Price, post-paid to any part of the country, $1.00. Send orders to this office.

Characteristics of Japanese Art.

A. CURTIS BOND.

THE principles of art necessarily lead to characteristic differences of development among nations. In a nation like Japan, so long excluded from the world, we find art working within certain formal and antique bounds, and this notwithstanding the marvelous variety given to productions and the facility of execution of the artists, who in realizing any given standard appear to trust little to chance, and achieving success with marvelous precision, apparently unburdened in thought with the details that go to make up the result.

Traditional and hereditary causes have manifestly endowed them with a love of art, which is put to good account in a thousand forms. Though we can never become their copyists, and occupying as we do higher ground in many leading spheres of art, there is much that is suggestive in the method and style of their work as to modes of artistic treatment which may be incorporated both in art designs and execution.

Decorative art in Japan owes much to the circumstance, that those engaged in it have been close students of nature. Ever on the alert for new and strange features, they proceed at once to give effect to these impressions, the hand closely following the head. The Japanese carver in wood has but to get the right conception, and he will work it out without a pattern, not failing, if it be a figure, to give to it individual expression, however crude it may otherwise be.

Take a Japanese two-leaved folding screen. Powerful contrasting effec s will be sought not in each separate tableau but between one and the other. This contrast is most effective in animal and human forms, and this in the attitudes they assume; indications of dominant but different instincts and feelings.

The glory of the lion may be said to be its strength, but who but a Japanese artist would have conceived the idea of combining the indication of such strength on the exterior of a bronze vase, with fear and impotent rage. The lion with front paws on a fallen tree trunk sees a winged dragon circled by dark thunder clouds in the air and appears to be exerting all his power to draw back from the fearful object on which his eyes are riveted, and yet to fail in the effort, as though enchained by some superior influence.

Quite in accordance with this spirit of contrast is the adorning the rounded edge of an elevated bronze dish with flying birds whose bodies protrude straight from the rim at given distances, their gills alone being attached to the plate.

An artistic surprise has, mentally considered, all the effect of a strong contrast, and the Japanese artist abounds with surprises; thus isolated human eyes will be seen peering out from different artistic objects, just where they would not be looked for, a practice for which, as also for the abounding circles in Japanese work, a symbolic purpose has been vainly sought; the fact being that the brightness of the eyes makes capital contrasts and assures some fun. The truth is that the vagaries of Japanese art require less to be analyzed than enjoyed, more especially with a design unique in itself.

The practical character of the Japanese mind leads to a combination of the *utile* with the artistic. Witness in bronze vases the employment of elephants' heads as decorations whilst their curled trunks serve as handles.

The Japanese lacquered wall-paper in colors or blended with gilding and silvering, shows in the deadened but attractive deep toned hues, and in the silvered rendering of floral subjects, or involved and flowing styles, a serious appreciation of mural artistic requirements and deep study to meet it. The designs are rich without tawdriness, and command admiration, both for the hues—many of which are wholly Eastern, the dyes apparently being vegetable dyes—and the admirable harmonious balancing of parts. If flowers are introduced, they are large and widely dispersed and no apparent continuity in the pattern is rudely broken in by furniture. An English lecturer has satirized their wall-paper as designed for the purpose of setting off their own figures, but no higher praise could well be accorded. These papers, which are beginning to be freely imported, abound with suggestions of treatment, especially in the relation of hues. Much of the decoration wears the appearance of being worked in leather, the dark brown surface being worked in small reticulated forms in intermediate spaces, contributing also its own shade to the colored design, which its hue thus aids in carrying out and strengthening.

In ornamenting objects the Japanese artist aims to avoid an exact repetition or counterpart of lines, or if he finds them, does all he can by means of decoration to destroy the direct effect of an exact division or repetition of any portion. He shuns an equality of parts or rather the appearance of equality of parts. Justice with him is not even handed, weighing with the steel yard instead of scales.

Division or repetition of parts, considered among western nations as the acme of ornamental as of architectural art, is recognized mainly by them in bronze constructions bearing as its center some deity or hero. The Japanese dislike diametrical division, preferring, for instance, to divide an oblong surface. Diaper patterns have not sufficient variety for them, and are too regular to cover surfaces.

Their delight in ornamenting surfaces is to follow the precedent of nature which never repeats herself in spangling the skies with stars or the earth with daises. Right angles, as a rule, are the horror of the Japanese artists. A square, which by the way, he cannot find in nature, offends his eye. He will carry up supports to the very edge of a box, round it off at the corner rather than endure it. To avoid it a tray will be shriveled up at its edges like an autumn leaf, or its raised sides will assume a scroll-like form.

It has been pointedly observed "that abhorring geometrical regularity of design, instead of planting his big bird in the center of a plate, like a tavern sign, the Japanese flings him down haphazard, straggling from the rim into the middle, but always with a pleasing and novel effect," qualities of conspicuous value in decoration.

The Japanese never produce a picture of the pictorial order that will stand any other test than the picturesque; relative position of objects is left to do the work of linear perspective; their use of light and shade is somewhat akin to that of *chiaro-oscuro*. Most of their carvings of the human face are typical, a droll sort of leer pervading all with Egyptian uniformity.

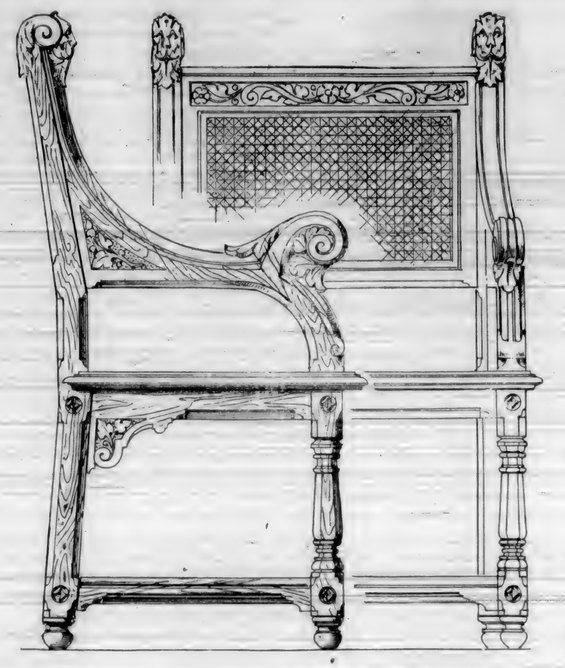
In the production of bronze works of art, both in design and workmanship, the Japanese show a marvelous excellence, epitomizing every form of grace suitable to it. Though much of the bronze work is grotesque there is a unity in the designs that may be studied with advantage.

One pleasing feature of Japanese art, which might be copied for dado and cabinet panels, is painting on dark colored wood, the veins of which are brought out in relief, like clouds in different strata, other portions being cut away with the exception of such parts as form a portion of the design. The bold treatment of the background gives force to the painting which is thrown forward, whilst the hue of the wood virtually serves as a surrounding shade.

The selection of teak, as the favorite wood for Japanese furniture work, is due to its extreme hardness as well as its rich ebony hue, the former quality allowing of minute and enduring carving, as in delicate piercing of apertures, or delineation of objects. It favors also the Japanese tendency to minimise material to the utmost, and affords a good contrast to *metallic* handles, light inlaid woods, or mother-of-pearl, not to mention silver.

Their sculptured, carved and modeled work shows a veritable passion for relief. Even their painted lacquer boxes are raised, and salient peculiarities of nature are faithfully depicted in every case, if only in the miniature carving of the interior of an egg shell, containing figures that must have been sculptured through the open chinks. We must give credit to the success of Japanese art on native subjects, particularly where there is action in social or animal life. In real works of art, the lower portion of the creation are finely rendered, particularly birds in flight. Like early artists of other nations, the Japanese make their point of sight very high, all figures being as if looked down upon. Japanese artists excel in the inexhaustible variety and deliciously eccentric beauty of their designs. Adroit and intelligent, they are forever originating new designs in form and color. It is an error to suppose that in their figures on porcelains, bronzes, textiles, wood, and paper they are always intent on representing grotesque traits. On the contrary, their paintings, castings, and carvings are replete with a serious spirit, with charming figures, costumes elegant and splendid, interiors rich and in good taste, whilst in their painted and embroidered stuffs and in their inlaid furniture, flowers, and other ornaments, are rendered without profusion, and with a marvelous regard to tasteful display; they never make the absurd pretension of deceiving the eye, but subordinate the ornament to the article, color where introduced assisting form by giving prominence to such parts as it is desirable to accent, and subordination to others which it is desirable to subdue.

In the present rehabilitation of ancient styles, treated freely with reference to artistic development from former conventional bounds, Japanese art may be regarded as exercising a wholesome suggestive influence—less in the way of actual novelty than in special modes of treatment.



THERE are several reasons upon which to base the strong hope for the future of the American mechanic. The multiplication, with the consequent cheapening, of technical journals, is one. Thousands of carpenters, and cabinet workers who a few years ago were content to do little if any reading, are now subscribers to one or more publications devoted to their line of work. That the exchange of ideas as thus brought about has greatly broadened the horizon of their work, goes without saying. The workman who reads must necessarily become a better workman for it. Again, the increasing disposition of practical men to write out their observations is a hopeful sign. The mechanic who trains himself to observe, note, and submit to writing his experience cannot help becoming more exact and intelligent in his work. Other important factors at work are the formation of mutual benefit societies among workmen, the establishment of reading rooms and libraries, the inauguration of lyceums and the increasing value with which the mechanic regards his right to vote—all pointing unmistakably to his rapid elevation to wider influence, greater usefulness, and an independence never before enjoyed by the class to which the intelligent mechanic belongs.—*The Builder and Wood-Worker.*

Furniture Woods.

ONE of the most flourishing, profitable and important branches of American industry is the manufacture of furniture. Not only do our factories supply the needs of 53,000,000 people, but scarcely a ship sails from our ports without carrying among her cargo specimens of this class of manufacture.

The American made furniture is preferred in many foreign countries for several reasons. The taste of the American artisan is refined and elegant, and the work he turns out is light and symmetrical, as well as strong and durable. While the English, French and German manufacturers still cling to their antiquated fashions and old methods, the Americans are constantly inventing new styles or improving on the old, and are thus in this branch of industry, as well as in many others also, far ahead of their transatlantic rivals.

Notwithstanding the excessive, and in many cases prohibitive, import duties that obtain in the majority of Latin-American countries, furniture of American manufacture is gradually becoming more and more fashionable. In Colombia, for instance, where the protective system is carried to exaggeration, cane bottom chairs, invoiced at $12 00 per dozen, pay $72.00 per dozen import duty. But while this high tariff has entirely prohibited the introduction of European-made furniture, each Atlas and Lombard steamer that sails from the ports of the Atlantic seaboard carries no inconsiderable quantity of this American line of goods, particularly parlor and bedroom sets, to South America.

But while this branch of American industry is so flourishing and so profitable, a feeling of uneasiness has begun to develop itself among our manufacturers. The domestic supply of hard wood is being gradually exhausted, and the price of raw material is becoming costly in proportion. The problem that agitates the manufacturing circles is "From whence shall we draw our future supply of furniture wood?" Their attention is daily becoming more intently fixed upon the tropical forests of Spanish America, and some of them have already taken steps to acquire possession of the timber lands that are most accessible to our ports.

The principal of the tropical furniture woods are cedar, rosewood and mahogany, for they are the best known and the commonest in use. But here again, another obstacle presents itself to the manufacturer. These woods have been utilized for furniture making for the past 250 years and the most accessible forests in tropical America have become almost denuded of marketable trees.

Such is emphatically the case with the timber lands of Santo Domingo, Jamaica, and the other West Indian Islands, and with those of Colombia, Venezuela, Mexico, and British Honduras also, while only Guatemala, Spanish Honduras, and Nicaragua possess supplies which, under the present circumstances, may be considered as fairly accessible.

Yet Mexico, Colombia, Venezuela, and British Honduras possess vast tracts of land covered with valuable furniture-wood forests, but which are at a long distance from the coast and from the river banks. The question that has already been agitated, how can these forests be rendered accessible? is answered by the demand of these localities for railroads. This subject has attracted the serious attention of European and American capitalists, who have already begun the construction, in several localities, of narrow-gauge railroads from the forest lands to the coast.

Thus the flourishing condition of the furniture traffic and the scarcity of the raw material has given birth to a railroad movement in the tropics that will eventually lead to the development of the vast agricultural, mineral and forest resources of Latin-America.—*Sel.*

Paper Hanging.

THE art of putting on or "hanging" paper, says an exchange, is very simple and is easily learned; but to make tasteful choice of paper for various situations is not so easy; hence the following remarks, which may be of service to the workman or others on whom the selection of paper may devolve:—

Walls to a room should be regarded only in the light of a framework to what the room coptains, and should be decorated so as to bring into prominence, and not eclipse, the other parts of the chamber. Nothing destroys the effect of a room so much as a handsome but staring wall paper, or a wall so profusely ornamented as to strike upon the eye to the exclusion of the rest of the decorations, thus bringing forward what should be the background into the most conspicuous place. A modern drawing-room is always difficult to decorate artistically, because of the taste of its builders for heavy cornices, prominent mantel-pieces and rooms too lofty for their size; and as all these mis-named "embellishments" are too costly to remove by tenants, the only plan to pursue is to destroy their effect by exercising both taste and ingenuity. First with regard to the ceiling; the ornamental plaster boss in its center should be removed and the ceiling tinted a color that harmonizes with the wall paper, as no harmonies can be hoped for when what produces them is surmounted with the glaring white of an ordinary ceiling. The tint used must be one that softens into the wall paper, not one that contrasts: thus, if the tone of the room is that of a soft gray-blue, the ceiling should be a clear flesh-pink; or should a grayish-green picked out with black be the chosen color, then it should be colored a subdued lemon.

Some people cover their ceilings with whole colored paper, and border it with a stenciled pattern representing the thin garlands so familiar upon Queen Anne decorations, but this is a more troublesome plan than the simple coloring, which answers all the purpose. The walls, if they are lofty, require a high dado. These high dados give a look of comfort and "home" that is absent from the modern, high-pitched room papered with one uniform pattern. The dado is divided three to four feet from the ceiling, and the coloring of the lower portion must always be heavier than that used on the upper, or a top-heavy look will be given to the room. When many pictures are to be hung up, the lower part of the dado should be of a whole color—either a whole colored paper or a painted wall—as pictures are only shown off upon such a background. Where a whole tint is used for the lower part of the dado, the upper portion should be decorated with a frieze paper of a good, bold pattern, but of subdued coloring and of tint that harmonizes with the lower. Thus, the color used about the frieze should be the same as that on the lower part, but of a lighter shade, intermixed with some other colors that form a harmonious link between the two shades. Contrasts must be carefully avoided, but pale pinks, blues and ambers can be blended together above a subdued gray-blue ground. The two portions of the dado should be joined together with a light wooden (black or brown) railing, or with a line of paint. The dado decoration can be altered by placing the pattern paper upon the lower part and leaving the upper part plain colored, with or without a stenciled pattern upon it. This will suit a room where not many pictures are required, or that is already rather dark. Some part of the wall should always be in plain color, as the eye requires rest, and no pattern, however subdued in hue, can give the relief to the mind that a bit of plain coloring affords, and this scarcity of ornament in one part of the room is amply repaid by the effect it gives to such parts as are bright and require to be bright. The true theory of effect is to use but one or two bright colors in a room, and to surround them by soft and subdued tints that throw up and do not destroy their brilliancy; a number of bright colors placed together destroy each other, and leave no impression upon the mind but glare and vulgarity. Having settled upon your paper and ceiling, have the woodwork and cornice of the room painted either a shade lighter or darker than the walls, and shroud up the mantel-piece with curtains, etc., of satin sheeting embroidered with crewels, and instead of the usual looking-glass over the fireplace, have a mirror surrounded with brackets holding china, or have a black, wooden mantel-piece made with squares of looking-glass set in. The background of your room being thus completed in a manner really to be a background, your furniture will look twice as well as if it were stared out of countenance by the walls; and one need hardly add that all your friends will delight in a room that throws up and brings out their dresses and faces, instead of killing them by its glaring tints.

Iron Shutters.

CORNICE manufacturers and others are frequently called upon to build iron shutters, and almost every shop has its own peculiar patterns or its own method of construction applicable to articles of this kind. The use of iron shutters is very general, especially in large cities and upon manufacturing establishments. They are to a certain extent not only tolerated, but strongly recommended, by the insurance companies, and yet there are objections to them which are so weighty that a careful consideration of the subject would seem to warrant a substitution of some other material or the abolishment of shutters altogether. One of the daily papers, in discussing this question a short time since, asserted that experience has proven iron shutters to be among the worst obstacles that firemen have to contend with in striving to enter burning buildings. The time taken to batter them open is for the advantage of the flames, and when the firemen get enough of the shutters open to permit water to be thrown into the building, they find that a fire that was of little account when first discovered has acquired almost resistless energy. From this it argues that it is practically certain that a fire originating in a building whose windows are sealed with iron shutters will destroy the building. It asserts that the idea that iron shutters keep fire out is also a fallacy, and then proceeds to state that flames on the outside of a building will frequently heat iron shutters red-hot. It also asserts that shutters cannot be made so tight that small sparks may not pass them, and instances the fact that merchandise of the value of $2,000,000 was destroyed in Brooklyn some time since, by a fire started by sparks from a fire-engine that was at work in front of the building, the sparks having passed through crevices at the hinges of the shutter.

While the naked statements presented by the journal above quoted are perhaps incontrovertible, it still remains that there is much in favor of the iron shutter, and many reasons may be given for believing a building to be better protected with iron shutters than without any shutters at all. Some of the objections raised apply particularly to shutters made of a single thickness of iron, which are likely to warp whenever subjected to a considerable degree of heat. It is hardly necessary for us to argue in this connection against shutters constructed in this manner, or in favor of those made of two thicknesses of iron, preferably corrugated, with an air chamber between them. Our readers will know that a shutter embodying this principle, properly made, is not likely to give trouble on account of warping. The fact that shutters are locked from the inside in such a way as to make it difficult for firemen to enter the building in order to fight the flames is certainly wrong, and the intelligent care of property should suggest some plan by which the shutters could be opened from the outside in case of necessity. The fact that sparks are sometimes drawn into buildings through crevices in the shutters, it seems to us, argues more than would at first be supposed. The true province of the shutters is to protect the building from fire, yet their presence induces carelessness upon the part of employers and others in caring for the building in other respects. Sparks would hardly be drawn through the crevices of iron shutters if the windows inside the shutters were properly closed. It would seem that if proper precautions were taken to keep windows shut, thus closing the building as carefully as though no shutters were in use, and relying upon the latter simply as a fire protection, it would overcome this class of objections to which the paper above mentioned alludes.

MORE than three-fourths of the cedar used in cedar pencils is shipped from Florida.

Every property owner should subscribe for the "CALIFORNIA ARCHITECT AND BUILDING NEWS." It is the only Journal on the Pacific Coast published strictly to advance your interests. Only $2.00 per annum.

To Keep Down House Insects.

OF course scrupulous cleanliness will dispose of most of them. Keep the yard free from decaying vegetables, refuse from the kitchen and the drain of the sink, and sweeten the out-buildings with lime, and flies will mostly emigrate to promising quarters. The few stragglers which remain can be nearly excluded by frames covered with millinet placed in the windows when open. These will also keep out the vexatious mosquito. Myriads of these latter insects are often bred in swamp spots adjoining the dwelling. Proper drainage will route them at head quarters. The rain-water cistern is also prolific in mosquitoes: place a few lively minnows or other brook fish there, and they will fatten on the larvæ of the tormenting insect—thus the biter will be bitten.

The flea delights in the dust and litter of the wood-house and the wagon-shed. Remove all this, sprinkle fresh lime in its place, add whitewash to the beams and boards, and the fleas will soon vanish. Take up all the carpets, beat them thoroughly with a slender rod, and scatter pepper around the sides of the room where the edges of the carpet are to be laid. Then, once a fortnight, whip the outside breadths upon the floor with a light switch and the remaining moths will be beaten out.

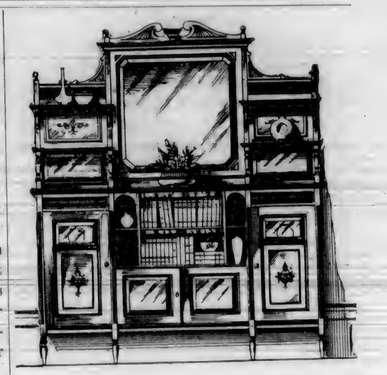
The chinch, or bed-bug, can be routed by first washing all parts of the bedstead with cold water, and then, with a brush, applying corrosive sublimate dissolved in spirits, of an amalgam of lard and quicksilver rubbed together. Or ask your druggist for six cents worth of unguentum; mix it with lamp oil, and apply it with a brush to all joints and crevices, when the bugs will sleep, and allow you to do the same.

Carpet Beating.

WE have no wish to decry this periodic purification, but merely to point out rules for its better conduct and efficiency. The usual process in households which cannot afford to have it carried out by special agency is first to take up the carpets and sweep the walls and ceilings, and then to wash the floors. While the latter are drying, work must be found for the idle hands, and they cannot be better employed than in beating the carpets in the court-yard or back garden, a work attended with a horrid din and clouds of dust. It will not be unavailing, we know, to complain of the noise—no appeal in this direction will gain a moment's sympathy; but we hope more attention will be paid to the other nuisance. When we reflect on the nature of the dust thus raised, we are surprised that sane persons allow to be thus stirred up under their noses all the nauseous accumulations of dining-room, bed-room, and stair carpets, to say nothing of door mats, etc., into a fine dust, and which, thus dispersed, finds its way again into our houses in a form most readily accessible to our respiratory organs. Indeed, it is fortunate if the dust thus roused is only nauseous and not effective, since the desquamated cuticle of scarlet fever, the scabs of small-pox, the dried sputa of consumptive or whooping-cough patients, living parasites, and hairs from mangy cats and dogs may thus invade our rooms. Carpet-beating, we are aware, is forbidden in public thoroughfares; but it should, in any form, be prohibited within a reasonable distance of dwelling-houses; and for those who cannot afford to pay the small sum required to have their carpets and mats properly cleaned, the authorities should set aside some open space, to which, on stated days and at certain hours, persons might bring their carpets and have them beaten, without causing annoyance or danger to themselves or neighbors.—*Lancet*.

Why Chimneys Smoke.

AS A matter of fact they never do,—it is the wood that smokes. We make this statement not by way of facetiousness, but to bring the discussion to a strictly scientific basis. Since the new birth of the open wood fire, the old question of how to coax the smoke to go straight up the chimney flue, at all times and under all circumstances, has come again to the front; and the old controversy as to the relative magnitude of two stupendous but familar domestic evils is liable to be revived. It is not our purpose to give here and now all the infallible rules by which one of these—and doubtless the minor—can be cured, or better still, prevented, but simply to refer to one of the common reasons why smoke from a fire on the hearth falls out into the room occasionally, if not constantly, instead of going up to the skies where it belongs. Having stated that chimneys never smoke, it may be well to observe that they never "draw" either. Whatever goes up chimney—from Thomas Hood's chimney sweep to the steam from the kettle nose—is poked up from behind. Of course this amounts to the same thing practically as being drawn up, but it is well to remember that the same pushing force will just as readily lift air, shavings, ashes, steam or anything else that comes in its way as smoke. The point, therefore, is to so arrange the throat of the chimney that the smoke shall be caught first, and, like proud Korah's troop, be swallowed up before it has a chance to spill over into the room and before something else can be crowded into its place. Left to its own devices it would fall out of the fire-place and run over the floor like water. As the air in the room happens to be usually cooler and, therefore, heavier than that in the fire-place, it forces the latter upwards and the smoke with it. Now the tendency of the smoke, as soon as it is lifted against the back wall of the fire-place, is to fall forward, and this tendency is favored by the curving back against which it ascends. There is no objection to this curve which seems to keep the smoke within bounds, and it doubtless radiates more heat than if it stood erect, but the one point which should be insisted upon,



is that the face of this curve along which the smoke rises should strike, if it were continued (which it is not, being cut off by the broad throat of the flue), several inches above the lintel at the top of the fire-place opening. The smoke is then fairly caught in the ascending current of warm air and carried up and away.

A smoking fire-place may often be cured without any change of flue or chimney by simply bringing down the top either with a row of bricks or tiles, or by a piece of metal fitted in between the jambs. And this cure is effected not because the fire-place was originally too large or too shallow to "draw," but because the proper provision had not been made for entrapping the smoke and turning it into the rising stream of warm air.—*The Builder*.

THERE are many sound truths that deserve careful consideration which are every day overlooked by those who should treat them otherwise. Here is one clipped from the columns of a contemporary, which advertisers should take to heart: The success of trade papers so far has proved conclusively that the leading and most enterprising establishments have been convinced of their value as an advertising medium. The day is not far distant when all manufacturers, of whatever class, will recognize the fact that the journal published directly in their interest is one for them to advertise in. The principal reason for this is that a journal of this kind has only one class of readers, and they are the very ones the advertiser wants to reach. In a trade paper, then, he only pays for just what he receives. How many advertisers think of this? A *trade* paper with only 2,000 circulation is a much cheaper and better advertising medium for the manufacturer than a *newspaper* with ten times the circulation, at the same price per inch. We never look for a manufacturer's advertisement in a daily or a weekly newspaper, but if we want anything in any particular line of goods we look in the paper representing that line for the advertisements of the leading manufacturers. This is sound common sense in a nutshell.

Wells.

THE old way of digging a well and stoning it up so as to leave it about three feet in diameter, is, an Eastern contemporary remarks, a very good one if the water is to be drawn up with buckets; but if only with a pump, it is a very poor way; for if, as is the usual custom, the well be covered at the top, it leaves a very large space for dead air, which often becomes so bad that it affects the quality of the water, and also makes it unsafe to enter the well. When a well thus stoned has only a pump in it, the covering should be under water, or very near it; but if it is known that only a pump is to be used, the expense of stoning may be saved, and the water kept in a much better condition. This is done by digging the well in a dry time, and when dug as low as possible, a cement pipe, some two feet in diameter and two or three feet long, is sunk at the bottom, and worked down as low as possible by digging out the inside. The pipe should be covered with a flat stone, through the middle of which a two-inch hole has been drilled; directly over this hole stand up drain pipe, then begin to fill in the hole. When filled as high as the top of the first piece of drain pipe, put on another, being careful to have it straight with the other and the line perpendicular; continue filling and adding drain pipe until it is as high as the surrounding ground; or if the pump is not to stand directly over the well, then when it is filled within four feet of the surface put in the pump pipe and lead it off in trench to where the pump is to stand. When it is found that the pipe is all right, finish filling the well, leaving some durable mark that the position of the well may be known. A well of this kind is reliable and permanent, requiring no repair, the water is cool and free from impurities that open wells are subject to; no insects or animals can find their way into it, and the cost is not more than one-half that of a well that is stoned. If dug, as it should be, when the springs are low, a constant supply of water that is as pure as the underground springs, is secure. As the well is always full, there is no chance for bad air to injure the water, and, in fact, but little danger of pollution from surrounding cesspools compared to that of open wells.

VALUE OF TRIFLES.—A London builder was offered bricks one-eight of an inch below the regular thickness. "What matters an eight of an inch in a brick?" said the merchant. "It matters *three thousand* more bricks for my job," was the reply. In an establishment employing fifty hands a loss of one minute each time of ringing the bell means fifteen hours in a week; this shows the value of trifles.—*Laxton's Builder's Price Book.*

THE object of setting saws is to less n friction. The reason of greater power being requisite for cross cutting than for ripping is that the former is not parallel to the grain. In filing, the edges are, of course, beveled opposite ways. The sharp beveled edge will be outward on the side to which the tooth is bent.

Restoring the Fire-Place Chimney.

ONE of the most common laments concerning the houses built fifteen or twenty years ago and more, says the *Builder*, is caused by the want of that feature which is now felt to be so indispensable: a place for an open fire. Hundreds of old-fashioned chimneys whose foundations filled all the central portion of the cellar, leaving hardly more than a quadrangular tunnel under the house, were torn down and the space they occupied was converted into halls, passages, stairways or closets, a single slender shaft doing duty as a smoke flue for a half dozen or more air tight stoves.

Repentance speedily followed this destruction of the cherished abiding place of the household gods, but how to bring forth works meet for repentance, that is, to restore the chimney and the fire-place, has always been a troublesome problem.

It need not be. Like many other apparently serious difficulties, the obstacles in the way of constructing new chimneys and open fireplaces in any house old or new are apt to be more apparent than real. A chimney is a self-supporting member of the family, starting from the ground and running straight up through the roof; it asks no favor or privileges except a few square feet of room on each floor less than a common table requires, hardly more than an ordinary chair. Instead of diminishing the security of the building, if properly made, it will make it more substantial. There is no law requiring a chimney or a fireplace to be squarely in the center of a house, directly between two windows, or precisely in the middle of one side of a room. The fireplace may be cornerwise or one-sided, within the house or outside of the main walls, provided it rests on *terra firma* and rises well above the roof.

HEALTHY, spacious workshops always pay, and it is pleasing to note that manufacturers are beginning to recognize this fact and act upon it. The old-fogy notion that anything is good enough for the hewers of wood and the beaters of iron, that comfort and convenience are antagonistic, is being fast relegated to the shades. Manufacturers are learning that a good building rightly planned both adds to convenience and economizes space and time, and that the best work is obtained when the arrangements for the comfort and health of the workmen are most perfect. The rents paid for manufacturing premises, as a rule, are high enough to entitle the manufacturer to better accommodations, and the securing of such is a matter of justice and substantial benefit to employes. Honest artistic work is possible only when conditions are favorable; filthy, dimly lighted and badly ventilated shops or factories are not usually considered very favorable conditions.—*The Builder and Wood-Worker.*

PAPER is now used in Germany instead of wood in the manufacture of lead pencils.

Defective Castings.

IT is stated in the English papers that an examination of the broken girders of the fallen railway bridge at Denmark Hill showed that one of them was "honey-combed with air bubbles;" and it is assumed that, as this girder gave way, the extra weight thus thrown upon the others caused the accident. It is almost unnecessary to say, a correspondent in *Iron* says, that the so-called "air bubbles" are really hydrogen cells, and that the only explanation that has been (and probably ever will be) afforded of the source of this hydrogen is that, if not exclusively, it is mainly derived from the moisture of the atmospheric blast, which becomes decomposed on coming in contact with molten iron or steel, its hydrogen being thereupon absorbed by the metal. This occurs not only in the steel converter, but also in the blast furnace and in the remelting cupola. As a consequence, both steel and iron castings are unreliable, and a constant source of danger wherever their soundness is essential to safety; and they are accordingly unfitted for a number of important purposes for which forged metal, at a far higher cost, is considered necessary.

I do not propose, adds Mr. Fryer, to refer to any of the various methods and expedients which have been devised, and which are sometimes employed to cure the evil. It will, however, seem remarkable that no attempt has yet been made to get rid of the defect itself by eliminating the moisture from the blast, and thus removing the cause. One practical trial in that direction would go further to solve the whole question than all the theories that have been advanced, and all the laboratory experiments that have been tried since Dr. Muller's famous discovery of the real nature of the so-called "air bubbles" or "blowholes."

Sneezing and Shivering.

NATURE'S provision against the consequence of a "chill," and for the prevention of a "cold" are sneezing and shivering. A violent fit of sneezing often saves a chilled body the consequences of the nerve depression or "shock" to which it has been subjected, and this shock may in its first impression be very limited in its area: for example, the small extent covered by a draught of cold air rushing thorugh the crevice of a door or window. The nerve centres are aroused from their "collapse" by the commotion or explosive influence of the sneeze. If sneezing fails nature will try a shiver, which acts mechanically in this way. If this fails, the effects are likely to be very serious and bad consequences may ensue. The cold is slight when sneezing suffices to recover the nervous system quickly from its depression; and grave when even strong shivering fails to do so. In case of chill, with threatened cold, sneezing may be produced by a pinch of snuff of any kind. This is how some of the vaunted "cures" of snuff are brought about. Brisk exercise may also ward off the attack.—*Lancet.*

MASONS' and BUILDERS' EXCHANGE
OF SAN FRANCISCO,
Room 11, 314 Montgomery St.

BELOW will be found a list of the members composing this Exchange. Boxes are provided for each member, so that architects, owners, or others desiring the services of any particular member, or those having boxes who are not members, and yet whose business is directly connected with that of the Exchange, can readily secure the attendance of the party sought, by leaving a note in the respective boxes.

ROBERT MITCHELL, President, 807 Turk St., Box 26.
J. WAGNER, Wagner's Potrero Ave. bet. 22d and 23d Sts. " 3
CRAWFORD FERRIS, 9 Bourbon St. " 20
JOS. SMITH, 2933 Mission St. " 36
JOHN MCCARTHY, 2509 Folsom St. " 7
